Acronyms

AC	abdominal circumference	EFM	electronic fetal monitoring	L/S	lecithin-sphingomyelin ratio	PROM	prelabour rupture of membranes
ACOG	American College of Obstetricians and Gynecologists	eFTS	enhanced first trimester screen	LLDP	left lateral decubitus position	PTL	preterm labour
		EFW	estimated fetal weight	LMP	last menstrual period	QF-PCR	quantitative fluorescence-polymerase chain reaction
AFI	amniotic fluid index	FDP	fibrin degradation products	LMWH	low molecular weight heparin		
AFLP	acute fatty liver of pregnancy	FHR	fetal heart rate	MSAFP	maternal serum α-fetoprotein	RDS	respiratory distress syndrome
AFV	amniotic fluid volume	FISH	fluorescence *in situ* hybridization	MSS	maternal serum screening	RhIG	Rh immune globulin
AP	anteroposterior	FL	femur length	MTX	methotrexate	ROM	rupture of membranes
APGAR	appearance, pulse, grimace, activity, and respiration	FM	fetal movement	NIPT	non-invasive prenatal testing	SFH	symphysis fundal height
		FPG	fasting plasma glucose	NP	*nil per os* - nothing by mouth	SOGC	Society of Obstetricians and Gynaecologists of Canada
aPTT	activated partial thromboplastin time	FTS	first trimester screen	NST	non-stress test		
		GA	gestational age	NT	nuchal translucency	SVD	spontaneous vaginal delivery
APS	antiphospholipid antibody syndrome	GBS	Group B *Streptococcus*	NTD	neural tube defects	T1	first trimester
		GDM	gestational diabetes mellitus	OA	occiput anterior	T2	second trimester
ARDS	acute respiratory distress syndrome	GTN	gestational trophoblastic neoplasia	OCP	oral contraceptive pill	T3	third trimester
				OGCT	oral glucose challenge test	TENS	transcutaneous electrical nerve stimulation
BPP	biophysical profile	HC	head circumference	OGTT	oral glucose tolerance test		
CD	Caesarean delivery	HELLP	hemolysis, elevated liver enzymes, low platelets	ONTD	open neural tube defect	TOLAC	trial of labour after Caesarean
CMV	cytomegalovirus			OP	occiput posterior	TPN	total parenteral nutrition
CPD	cephalopelvic disproportion	IMM	intramyometrial	OT	occiput transverse	TTP	thrombotic thrombocytopenic purpura
CTG	cardiotocography	IOL	induction of labour	PAPP-A	pregnancy-associated plasma protein A		
CVS	chorionic villus sampling	IPS	integrated prenatal screen			TVUS	transvaginal ultrasound
DIC	disseminated intravascular coagulation	ITP	immune thrombocytopenic purpura	PG	plasma glucose	V/Q	ventilation/perfusion lung scan
				PPD	postpartum depression	VBAC	vaginal birth after Caesarean
DVT	deep vein thrombosis	IUFD	intrauterine fetal demise	PPH	postpartum hemorrhage	VWD	von Willebrand disease
ECV	external cephalic version	IUGR	intrauterine growth restriction	PPROM	preterm premature rupture of membranes	VTE	venous thromboembolism
EDD	estimated date of delivery	IVH	intraventricular hemorrhage				

Basic Anatomy Review

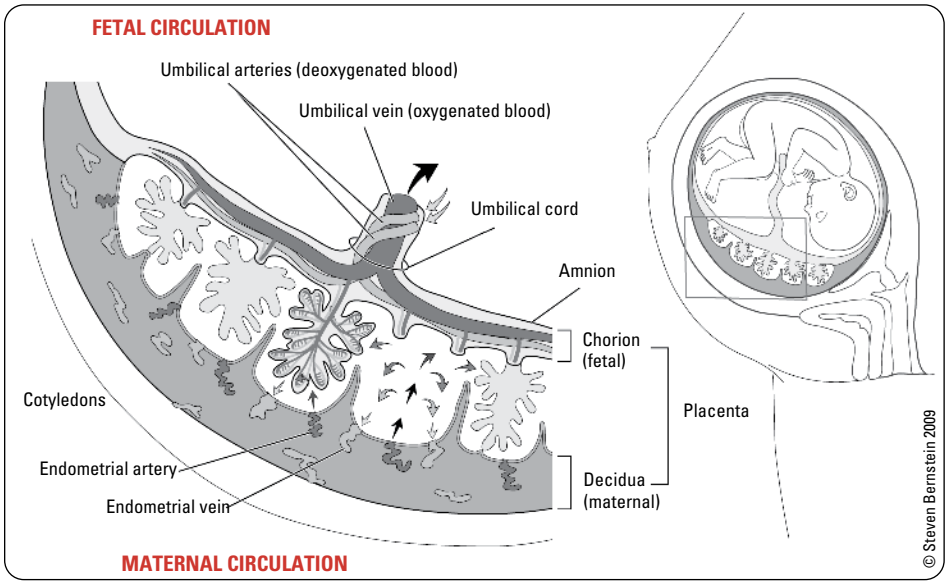

Figure 1. Placental blood flow

Placenta

- site of fetal nutritive, respiratory, and excretory function
- discoid mass composed of fetal (chorion frondosum) and maternal (decidua basalis) tissues divided by fissures into cotyledons (lobules) on the uterine side
- produces hormones such as progesterone, placental lactogen, estrogen, relaxin, β-hCG, and infant growth factors
- poor implantation can lead to spontaneous abortion
- abnormal location, implantation, or detachment can lead to antepartum hemorrhage (see *Antepartum Hemorrhage*, OB14)

Pregnancy

Diagnosis of Pregnancy

History

- symptoms: amenorrhea, N/V, breast tenderness, urinary frequency, and fatigue
- obstetrical and gynaecological history: year, location, mode of delivery, duration of labour, sex, gestational age, birth weight, and complications of every pregnancy; organize into GTPAL format, LMP, length of menstrual cycle, and use of contraception
  - gravidity (G)
    - G: total number of pregnancies of any gestation (multiple gestation=one pregnancy)
      - includes current pregnancy, abortions, ectopic pregnancies, and hydatidiform moles
  - parity (TPAL)
    - T: number of term deliveries (>37 wk GA)
    - P: number of preterm deliveries (20+0 to 36+6 wk GA)
    - A: number of abortions and ectopic pregnancies (ending <20 wk GA)
      - induced (therapeutic) and spontaneous (miscarriage)
    - L: number of living children

Be conscious of the use of gendered language when providing reproductive care to transgender male and gender-diverse patients. Discuss with each patient the terminology they are most comfortable using in order to avoid gender dysphoria throughout pregnancy care

Physical Signs

- uterine enlargement
- breast engorgement, areola darkening, and prominent vascular patterns
- Goodell's sign: softening of the cervix (4-6 wk GA)
- Chadwick's sign: bluish discolouration of the cervix and vagina due to pelvic vasculature engorgement (6 wk GA)
- Hegar's sign: softening of the cervical isthmus (6-8 wk GA)

Establishing the desirability of pregnancy in a patient with suspected or confirmed pregnancy informs the construction of an appropriate management plan

Investigations

- β-hCG: peptide hormone composed of β subunits produced by placental trophoblastic cells – maintains the corpus luteum during pregnancy
  - positive in serum 9 d post-conception, positive in urine 28 d after 1st day of LMP
  - plasma levels usually double every 1.4-2.0 d, peak at 8-12 wk GA, then fall, but continue to be measurable until delivery
- levels less than expected can suggest ectopic pregnancy, abortion, inaccurate dates, but found in some normal pregnancies
- levels greater than expected can suggest multiple gestation, molar pregnancy, trisomy 21, inaccurate dates, some normal pregnancies, or kidney disease (slower clearance)
- U/S:
  - transvaginal
    - 5 wk GA: gestational sac visible
    - 6 wk GA: fetal pole visible
    - 6-8 wk GA: fetal heart activity visible (FHR visible after 6 weeks on TVUS)
  - transabdominal
    - 6-8 wk GA: intrauterine pregnancy visible

β-hCG Rule of 10s
10 IU at time of missed menses
100000 IU at 10 wk GA (peak)
10000 IU at term

Trimesters
T1 (first trimester): 1-14 wk GA
T2 (second trimester): 14-28 wk GA
T3 (third trimester): 28-42 wk GA
Normal pregnancy term: 37-42 wk GA

Maternal Physiologic Adaptations to Pregnancy

Table 1. Physiologic Changes During Pregnancy

	Changes
Skin	Increased pigmentation of perineum and areola, chloasma (pigmentation changes under eyes and on bridge of nose), linea nigra (midline abdominal pigmentation), spider angiomas, palmar erythema due to increased estrogen, and striae gravidarum due to connective tissue changes
Cardiovascular	Hyper-dynamic circulation Increased cardiac output, heart rate, and blood volume Decreased blood pressure: decreased PVR and decreased venous return from enlarging uterus compressing IVC and pelvic veins Increased venous pressure leads to risk of varicose veins, hemorrhoids, and leg edema
Hematologic	Hemodilution causes physiologic anemia and apparent decrease in hemoglobin and hematocrit Increased leukocyte count but impaired function leads to improvement in some autoimmune diseases Gestational thrombocytopenia: mild (platelets >70000/μL) and asymptomatic, normalizes within 2-12 wk following delivery Hypercoagulable state: increased risk of DVT and PE but also decreased bleeding at delivery

PVR – pulmonary vascular resistance; IVC – inferior vena cava; FEV1 – forced expiratory volume in 1 second; CO – cardiac output; GFR – glomerular filtration rate; BUN – blood urea nitrogen; GERD – gastroesophageal reflux disease

Table 1. Physiologic Changes During Pregnancy

	Changes
Respiratory	Increased incidence of nasal congestion Increased O_2 consumption to meet increased metabolic requirements Elevated diaphragm (i.e. appears more "barrel-chested") Increased minute ventilation leads to decreased CO_2 resulting in mild respiratory alkalosis that helps CO_2 diffuse across the placenta from fetal to maternal circulation Decreased total lung capacity (TLC), functional residual capacity (FRC), and residual volume (RV) No change in vital capacity (VC) and FEV1
Gastrointestinal	GERD due to increased intra-abdominal pressure and progesterone (causing decreased sphincter tone and delayed gastric emptying) Increased incidence of gallstones due to progesterone causing increased gallbladder stasis Constipation due to progesterone causing decreased GI motility and hemorrhoids as a result of constipation and increased intra-abdominal pressure
Genitourinary	Increased urinary frequency due to increased total urinary output Increased incidence of UTI and pyelonephritis due to urinary stasis (see *Urinary Tract Infection*, OB31) Glycosuria that can be physiologic especially in the T3; consider testing for GDM if noted in first 2 trimesters Ureteric and renal pelvis dilation (R>L) due to progesterone-induced smooth muscle relaxation and uterine enlargement Increased CO and thus increased GFR leads to decreased creatinine (normal in pregnancy 35-44 mmol/L), uric acid, and BUN
Neurologic	Increased incidence of carpal tunnel syndrome, sciatica, and Bell's palsy
Endocrine	Thyroid: moderate enlargement (not clinically detectable) and increased basal metabolic rate Increased total thyroxine and thyroxine binding globulin (TBG) Normal free thyroxine index and TSH levels Physiologic suppression of TSH in T1 is common due to cross-reactivity of HCG to TSH receptors Adrenal: increased maternal cortisol throughout pregnancy (total and free) Calcium: decreased total maternal Ca^{2+} due to decreased albumin Free ionized Ca^{2+} (i.e. active) proportion remains the same due to parathyroid hormone (PTH), resulting in increased bone resorption and gut absorption, and increased bone turnover (but no loss of bone density due to estrogen inhibition) (see *Diabetes Mellitus*, OB28)

PVR – pulmonary vascular resistance; IVC – inferior vena cava; FEV1 – forced expiratory volume in 1 second; CO – cardiac output; GFR – glomerular filtration rate; BUN – blood urea nitrogen; GERD – gastroesophageal reflux disease

Antepartum Care

- can be provided by an obstetrician, family physician, midwife, or multidisciplinary team (based on patient preference and risk factors)

Preconception Counselling

- 3-8 wk GA is a critical period of organogenesis, so early preparation is vital
- PMHx: optimize medical conditions and review medications prior to pregnancy (see *Medical Complications of Pregnancy*, OB28 and *Medications*, OB13)
- supplementation
  - folic acid: see *Counselling of the Pregnant Patient*, OB12 and *Medical Complications of Pregnancy*, OB28
- prenatal vitamins (PNV), consider iron supplementation in T2 and T3 (earlier in cases of iron deficiency anemia)
- lifestyle/social: smoking, alcohol, drug use, domestic violence, occupational risks, poor social support, balanced nutrition, and physical fitness (see Family Medicine)
- medications: discuss teratogenicity of medications so they may be adjusted, replaced, or stopped if necessary
- infection screening: rubella, HBsAg, VDRL, Pap smear, gonorrhea/chlamydia, HIV, TB testing based on travel and working in health care, history of varicella or vaccination, and parvovirus immunity if exposed to small children
- genetic testing as appropriate for high-risk groups (see *Prenatal Screening*, Table 2, OB7); consider genetics referral in known carriers, recurrent pregnancy loss/stillbirth, family members with developmental delay, birth anomalies, genetic diseases, and consanguinity

Initial Prenatal Visit

- usually within 8-12 wk of the 1st day of LMP or earlier if <20 or >35 y/o, bleeding, very nauseous, or other risk factors present

History

- gestational age by dates from the 1st day of the LMP
  - Naegele's rule: 1st day of LMP + 1 yr + 7 d – 3 mo
  - e.g. LMP = 1 Apr 2021, EDD = 8 Jan 2022 (modify if cycle not 28 d by adding number of d >28 or subtracting number of d <28)
  - EDD by LMP not reliable if irregular menstrual cycle, or if patient unsure of the LMP

Family physicians and midwives can consider OB consultation for conditions including:
- Insulin-dependent GDM
- TOLAC
- Multiple gestation
- Malpresentation
- Active antepartum hemorrhage
- PTL/PPROM
- Failure to progress/descend
- Induction/augmentation if high-risk
- Tears: 3rd or 4th degree
- Retained placenta
- IUGR
- Postpartum hemorrhage

Note: Guidelines vary by institution and by provincial midwifery colleges

Advise all patients capable of becoming pregnant to supplement their diet with 0.4 mg/d of folic acid (CTFPHC Grade II-2-A Evidence)

Prenatal and genetic screening are voluntary and require proper counselling and informed consent before proceeding. HIV screening is done automatically in some provinces as opt-out testing; need to inform patient of this

- dating U/S should be offered to all woman
- EDD by T1 U/S after 7 wk more reliable than LMP if difference is greater than 5 d from LMP due date
- history of present pregnancy (e.g. bleeding, N/V) and all previous pregnancies
- past medical, surgical, and gynaecological history
- prescription and non-prescription medications
- family history: diabetes, hypertension, thyroid disease, mental health issues, genetic diseases, birth defects, multiple gestation, and consanguinity
- social history: smoking, alcohol, and substance use
- intimate partner violence screening: look for bruising, improbable injury, depression, late prenatal care (presenting at T2 or T3), missed prenatal visits, and/or appointments cancelled on short notice (see Family Medicine, *Intimate Partner Violence*, FM30)

In history of previous pregnancies, **ALWAYS** ask:
GTPAL
Year
Sex
Weight
Gestational age
Mode of delivery
Length of labour
Complications

Physical Exam
- complete physical exam to obtain baseline patient information – BP and weight important for interpreting subsequent changes
- BMI for risk stratification (risk of DVT, GDM, and preeclampsia all increase with greater BMI)

Ask every woman about abuse – not just those whose situations raise suspicion of abuse AND ask as early as possible in pregnancy

Investigations
- blood work
  - CBC, blood group and Rh status, antibody screen, and infection screening as per preconception counselling
- urine routine & microscopic, midstream urine C&S
  - screen for bacteriuria and proteinuria
- pelvic exam
  - Pap smear (only if required according to patient history and provincial screening guidelines), cervical or urine PCR for *N. gonorrhoeae* (GC) and *C. trachomatis* (CT)

Estimated Date of Delivery (EDD) Determination
- By LMP if menses regular, patient reliable historian
- By T1 U/S
- By embryo age and date of transfer if *in vitro* fertilization
- T1 U/S up to 13+6/7 wk GA is most accurate method of establishing GA
- Changes to the EDD must be documented and discussed with the patient
- Pregnancy without U/S confirming or revising the EDD prior to 22+0/7 wk GA is considered sub-optimally dated

Nausea and Vomiting

Epidemiology
- affects 50-90% of pregnant women
- often limited to T1 but may persist beyond this

Management
- rule out other causes of N/V especially if refractory to initial therapy
- weigh frequently, assess level of hydration, and test urine for ketones
- non-pharmacological
  - frequent small meals (bland, dry, salty are better tolerated), encourage any safe appealing foods
  - electrolyte oral solutions (Pedialyte®, Gatorade®)
  - stop prenatal vitamins and if T1, substitute with folic acid or adult/children's vitamins that are low in iron
  - increase sleep/rest
  - ginger (maximum 1000 mg/d)
  - acupuncture, acupressure, and mindfulness-based cognitive therapy
- pharmacological
  - first line: pyridoxine (B6) monotherapy or doxylamine/pyridoxine (Diclectin®) combination 4 tablets PO daily (1 q AM, 1 q lunch, and 2 qhs) up to maximum of 8 tablets/d
  - H1 receptor antagonists should be considered for acute or chronic episodes of N/V in pregnancy
  - metoclopramide and phenothiazines can be used as an adjunctive therapy for severe N/V in pregnancy
  - ondansetron if severe N/V and other anti-emetics have failed
  - consider use of acid-reducing medications as adjunctive therapy (e.g. antacids, H2 blockers, proton pump inhibitors)
- severe/refractory
  - consider homecare with IV fluids and parenteral anti-emetics, hospitalization

Hyperemesis Gravidarum

Definition
- intractable N/V, usually presents in T1 then diminishes; occasionally persists throughout pregnancy
- affects ~1% of pregnancies

Etiology
- multifactorial with hormonal, immunologic, and psychological components
- rapidly rising β-hCG ± estrogen levels may be implicated

Investigations
- rule out systemic causes: GI, pyelonephritis, thyrotoxicosis
- rule out other obstetrical causes: multiple gestation, GTN
- CBC, electrolytes, BUN, creatinine, LFTs, urinalysis
- U/S

Management
- thiamine supplementation may be indicated
- non-pharmacological (see *Nausea and Vomiting*, OB5)
- pharmacological options
  - doxylamine/pyridoxine (for dosage, see *Nausea and Vomiting*, OB5)
  - dimenhydrinate can be safely used as an adjunct to Diclectin® (1 suppository BID or 25-50 mg PO QID)
  - other adjuncts: hydroxyzine, pyridoxine, phenothiazine, or metoclopramide
  - also consider: ondansetron or methylprednisolone (avoid steroids in T1 due to increased risk of oral clefting)
  - if severe: admit to hospital, NPO initially then small frequent meals; correct hypovolemia, electrolyte disturbance, and ketosis; TPN (if very severe) to reverse catabolic state

Complications
- maternal
  - dehydration, electrolyte, and acid-base disturbances
  - Mallory-Weiss tear
  - Wernicke's encephalopathy, if protracted course
  - death
- fetal: usually none, IUGR is 15x more common in women losing >5% of pre-pregnancy weight

Subsequent Prenatal Visits

Timing
- for uncomplicated pregnancies, SOGC recommends q4-6 wk GA until 30 wk, q2-3 wk from 30 wk GA, and q1-2 wk from 36 wk GA until delivery

Assess at Every Visit
- estimated GA
- history: FM, vaginal bleeding, leaking, cramping, questions, and/or concerns
- physical exam: BP, weight gain, SFH, Leopold's maneuvers (T3) to determine the lie, position, and presentation of fetus
- investigations: urinalysis for proteinuria in high-risk women (hypertensive patients); FHR starting at 10-12 wk using Doppler U/S

Leopold's Maneuvers
- performed after 30-32 wk GA
- first maneuver: to determine which fetal part is lying furthest away from the pelvic inlet
- second maneuver: to determine the location of the fetal back
- third maneuver: to determine which fetal part is lying above the pelvic inlet
- fourth maneuver: to locate the fetal brow

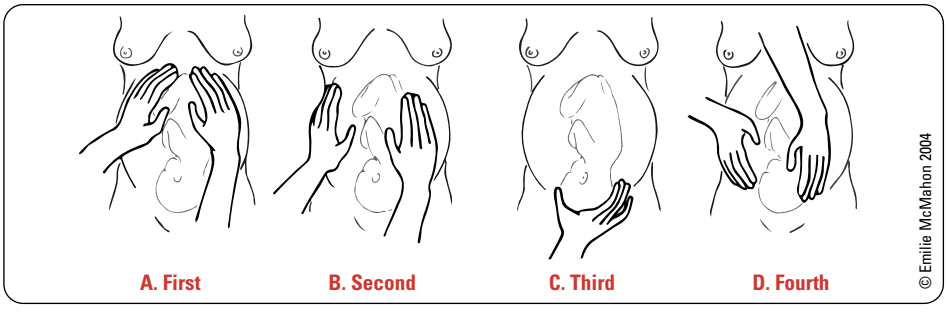

Figure 2. Leopold's maneuvers (T3)
Reprinted with permission from Essentials of Clinical Examination Handbook, 6th ed. Lincoln, McSheffrey, Tran, Wong

Symphysis Fundal Height (SFH)

12 wk GA	Uterine fundus at pubic symphysis
16 wk GA	Fundus halfway from pubic symphysis to umbilicus
20 wk GA	Fundus at umbilicus
20-36 wk GA	SFH should be within 2 cm of GA

SFH < Dates
- Date miscalculation
- IUGR
- Fetal demise
- Oligohydramnios
- Early engagement
- Transverse lie

SFH > Dates
- Date miscalculation
- Multiple gestation
- Polyhydramnios
- Large for gestational age (familial, DM)
- Fibroids

Prenatal Screening and Diagnostic Tests

Screening Tests

- testing should only occur following counselling and with informed consent from the patient

Table 2. High-Risk Population Screening Tests

Disease (Inheritance)	Population(s) at Risk	Screening Test(s)
Thalassemia (AR)	Individuals from these regions: Mediterranean, South East Asia, Western Pacific, Africa, Middle East, Caribbean, South America	CBC (MCV and MCH), Hb electrophoresis, or HPLC
Sickle Cell (AR)	Individuals from these regions: Africa, Caribbean, Mediterranean, Middle East, India, South America	CBC (MCV and MCH), Hb electrophoresis, or HPLC
Cystic Fibrosis (CF) (AR)	Family history of CF in patient or partner or medical condition linked to CF like male infertility	CFTR gene DNA analysis
Tay Sachs Disease (AR)	Ashkenazi Jewish*, French Canadians, Cajun	Enzyme assay HEXA or DNA analysis HEXA gene
Fragile X Syndrome (X-linked)	Family history – confirmed or suspected	DNA analysis: FMR-1 gene

AR = autosomal recessive; HEXA = hexosaminidase A; HPLC = high performance liquid chromatography
*If both partners are Ashkenazi Jewish, test for Canavan disease and Familial Dysautonomia (FD); if family history of a specific condition, look for carrier status: e.g. Gaucher, CF, Bloom syndrome, Niemann-Pick disease, etc. In all cases, if both partners are positive, refer for genetic counselling.

Table 3. Gestation-Dependent Screening Investigations

Gestational Age (wk)	Investigations	Details
8-12	Dating U/S, possible Pap smear, chlamydia/gonorrhea testing, urine C&S (detect asymptomatic bacteriuria), HIV, VDRL, HBsAg, Rubella IgG, Parvovirus IgM if symptomatic or IgG if high-risk (small child at home or daycare worker/primary teacher), Varicella IgG if no history of disease/immunization, CBC, blood group and screen	
>10	NIPT	Measures cell-free fetal DNA in maternal circulation
10-12	CVS	Diagnostic test, NOT screening
11-14	Enhanced FTS or IPS Part 1	
11-14	Nuchal translucency U/S	Measures 1. Nuchal translucency on U/S 2. β-hCG 3. PAPP-A 4. Placental growth factor (enhanced FTS only) 5. MSAFP (enhanced FTS only)
15-16 to term	Amniocentesis	Diagnostic test, NOT screening
15-20	IPS Part 2	Measures 1. MSAFP 2. β-hCG 3. Unconjugated estrogen (estriol or μE3) 4. Inhibin A
15-20	MSS	Measures 1. MSAFP 2. β-hCG 3. Unconjugated estrogen (estriol or μE3) 4. Inhibin A
18-20 to term	FM (quickening)	
18-20	U/S for fetal size, anatomy assessment, and placental location	
24-28	Gestational Diabetes Screen OGCT 50 g	See *Diabetes Mellitus*, OB28
28	Repeat CBC +/- ferritin RhIG for all Rh-negative women	
35-37	GBS screen	See *Early-Onset Group B Streptococcus*, OB30
6 wk postpartum	Discuss contraception, menses, breastfeeding, depression, mental health, and support Physical exam: breast exam, pelvic exam including Pap smear (only if due as per provincial screening), wounds assessment (perineum or C-section scar)	

Maternal serum screen is also referred to as Triple Screen; if Inhibin A is also tested, it is referred to as Quadruple Screen
Can consider ordering AFP to screen for open neural tube defects in women with BMI >40

Routine T2 U/S at 18-22 wk GA Helps to Determine:

- Number of fetuses
- GA (if no prior U/S)
- Location of placenta
- Fetal anomalies

DDx of Increased MSAFP

- Incorrect GA
- >1 fetus (e.g. twins)
- Fetal loss
- ONTD
- Abdominal wall defects (e.g. omphalocele)

ULTRASOUND SCREENING

- 8-12 wk GA: dating U/S (most accurate form of pregnancy dating)
- measurement of crown-rump length (margin of error: ± 5 d)
- EDD should be based on T1 U/S if available
- 11-14 wk GA: U/S for NT
- measures the amount of fluid behind the neck of the fetus
- early screen for trisomy 21 (may also detect cardiac anomalies and other aneuploidies like Turner syndrome)
- NT measurement is necessary for the FTS and IPS Part 1
- 18-20 wk GA: growth and anatomy U/S (margin of error: ±10 d)
- earlier or subsequent U/S performed when medically indicated

NON-INVASIVE PRENATAL TESTING (NIPT)

- analyses maternal blood for circulating cell-free fetal DNA (ccffDNA) at 10 wk GA onwards. Requires dating U/S for accuracy

Advantages

- increased accuracy (high detection rate (DR), low false positive rate (FPR))
  - trisomy 21 (DR 99%, FPR 0.1%), highly sensitive
  - trisomy 18 (DR 96%, FPR 0.1%), trisomy 13 (DR 91%, FPR 0.1%)
  - Turner syndrome (DR 90%, FPR 0.2%)
  - other disorders (DiGeorge syndrome, Cri Du Chat, Prader-Willi, Angelman syndrome, XY disorders)
- earlier timing with results available in 1-2 wk where parents can potentially have a CVS at 10-12 wk for diagnosis over an amniocentesis after 15 wk

Disadvantages

- does not screen for ONTD
- not covered by most provincial health insurance systems
- need to confirm with invasive testing (it is a screening test, not a diagnostic test)
- obtaining a result depends on sufficient fetal fraction (affected by the GA, maternal obesity, and presence of a chromosome aneuploidy in either the placenta or the mother)
- does not test for all aneuploidies
- gives no result in 1-5% of cases (insufficient fetal fraction, more common with elevated BMI)

Table 4. Comparison of FTS, MSS, and IPS

eFTS	MSS	IPS
11-14 wk GA	15-20 wk GA	11-14 wk GA: U/S-nuchal translucency 11-14 wk GA: eFTS blood 15-20 wk GA: MSS blood including inhibin A
Risk estimate for 1. Down syndrome (trisomy 21): increased NT, increased β-hCG, decreased PAPP-A 2. Trisomy 18: increased NT, decreased PAPP-A	Risk estimate for 1. ONTD: increased MSAFP (sensitivity 80-90%) 2. Trisomy 21: decreased MSAFP, increased β-hCG, decreased μE3 (sensitivity 65%) 3. Trisomy 18: decreased MSAFP, decreased β-hCG, decreased μE3, decreased inhibin A (sensitivity 80%)	Risk estimate for ONTD, trisomy 21, trisomy 18 Sensitivity ~85-90% 2% false positive rate Patients with positive screen should be offered U/S and/or amniocentesis or NIPT (covered in some provinces, self-pay in others)
Note: Useful when patient wants results within the T1		
More accurate estimate of Down syndrome risk than MSS, sensitivity ~85% (when combined with age)	Only offered alone if patient missed the time window for IPS or eFTS	
5% false positive rate	8% baseline false positive rate for trisomy 21, lower for NTD and trisomy 18	
Patients with positive screen should be offered CVS, amniocentesis, or NIPT (covered in some provinces, self-pay in others)	Patients with positive screen should be offered U/S, amniocentesis, or NIPT (covered in some provinces, self-pay in others)	

Note: In twins, eFTS, MSS, and IPS are not applicable; screen with NT, NIPT for chromosomal abnormalities, and MSAFP for ONTDs

Diagnostic Tests

- diagnostic tests available:
  - amniocentesis
  - chorionic villus sampling

Indications

- age >35 yr (increased risk of chromosomal anomalies)
  - risk factors in current pregnancy
  - abnormal U/S
- abnormal prenatal screen (IPS, eFTS, MSS, or NIPT)
- past history/family history of:
  - chromosomal anomaly or genetic disease
  - either parent a known carrier of a genetic disorder or balanced translocation
  - consanguinity
  - >3 spontaneous abortions

AMNIOCENTESIS

- U/S-guided transabdominal extraction of amniotic fluid performed as early as 15 wk GA

Indications

- identification of genetic and chromosomal anomalies (15-16 wk GA) as per indications above
- confirmation of positive NIPT testing
- positive eFTS/IPS/MSS
- assessment of fetal lung maturity (T3) via the L/S ratio
  - if >2:1, RDS is less likely to occur

Advantages

- also screens for ONTD (acetylcholinesterase and amniotic AFP) – 96% accurate
- in women >35 yr, the risk of chromosomal anomaly (1/180) is greater than the risk of miscarriage from the procedure
- more accurate genetic testing than CVS

Disadvantages

- 1/200 to 1/900 risk of procedure-related pregnancy loss, depending on local experience
- results take 14-28 d; QF-PCR or FISH can be done on chromosomes X, Y, 13, 18, 21, 22 to give preliminary results in 48 h; chromosomal microarray also readily available

Compared to CVS, amniocentesis has a higher accuracy of prenatal cytogenetic diagnosis (99.8% vs. 97.5%) and lower risk of spontaneous abortion (0.5% vs. 1-2%)

Risk Factors for Neural Tube Defects

GRIMM
Genetics: family history of NTD (risk of having second child with NTD is increased to 2-5%), consanguinity, chromosomal (characteristic of trisomy 13, 18, and 21)
Race: Higher risk in Europeans and non-Hispanic whites than African Americans, 3-fold higher in Hispanics
Insufficient vitamins: zinc and folate
Maternal chronic disease (e.g. DM)
Maternal use of antiepileptic drugs

General population risk for NTD is 0.1%

CHORIONIC VILLUS SAMPLING

- biopsy of fetal-derived chorion using a transabdominal needle or transcervical catheter at 10-12 wk GA

Advantages

- enables pregnancy to be terminated earlier than with amniocentesis
- rapid karyotyping and biochemical assay within 48 h, including FISH analysis
- high sensitivity and specificity

Disadvantages

- 1% risk of procedure-related pregnancy loss
- does not screen for ONTD
- 1-2% incidence of genetic mosaicism "false negative" results

ISOIMMUNIZATION SCREENING

Definition

- isoimmunization: antibodies (Ab) produced against a specific RBC antigen (Ag) as a result of antigenic stimulation with RBC of another individual

Etiology

- maternal-fetal circulation normally separated by placental barrier, but sensitization can occur and can affect the current pregnancy, or more commonly, future pregnancies
- anti-Rh Ab produced by a sensitized Rh-negative mother can lead to fetal hemolytic anemia
- risk of isoimmunization of an Rh-negative mother with an Rh-positive ABO-compatible infant is 16%
- sensitization routes
  - incompatible blood transfusions
  - previous fetal-maternal transplacental hemorrhage (e.g. ectopic pregnancy, trauma, abruption)
  - invasive procedures in pregnancy (e.g. prenatal genetic diagnosis, cerclage, D&C)
  - any type of abortion
  - labour and delivery
  - trauma (e.g. car accident, fall, etc.)

Rh Antibody Titre
A positive titre (≥1:16) indicates an increased risk of fetal hemolytic anemia

Investigations

- screening with indirect Coombs test at first visit for blood group, Rh status, and antibodies
- Kleihauer-Betke test used to determine extent of fetomaternal hemorrhage by estimating volume of fetal blood volume that entered maternal circulation
- detailed U/S for hydrops fetalis
- middle cerebral artery Dopplers are done to assess degree of fetal anemia; if not available, bilirubin is measured by serial amniocentesis to assess the severity of hemolysis
- cordocentesis for fetal Hb should be used cautiously (not first-line)

Standard dose of 300 µg of Rhogam® sufficient for 30 mL of fetal blood. Give additional 10 µg of Rhogam® for every mL of fetal blood over 30 mL

Prophylaxis
- exogenous Rh IgG (Rhogam® or WinRho®) binds to Rh antigens of fetal cells and prevents them from contacting maternal immune system
- Rhogam® (120-300 µg) given to all Rh-negative and antibody screen negative women in the following scenarios:
  - routinely at 28 wk GA (provides protection for ~12 wk)
  - within 72 h of the birth of a Rh-positive fetus
  - with any invasive procedure in pregnancy (CVS, amniocentesis)
  - as part of management of ectopic pregnancy
  - with miscarriage or therapeutic abortion
  - with an antepartum hemorrhage
  - with trauma
- Rhogam® 300 µg provides sufficient prophylaxis for 30 mL fetal Rh-positive whole blood
- a Kleihauer-Betke test or flow cytometry can be used to measure the relative quantity of fetal blood in maternal circulation to determine if additional Rhogam® is indicated (if >30 mL fetal blood)
- if Rh-negative and Ab screen positive, follow mother with serial monthly Ab titres throughout pregnancy + U/S ± serial amniocentesis as needed (Rhogam® has no benefit, as B cells sensitized antibodies already in circulation)

Treatment
- falling biliary pigment warrants no intervention (usually indicative of either unaffected or mildly affected fetus)
- intrauterine transfusion between 18-35 wk GA of O-negative packed RBCs may be required for severely affected fetus
- early delivery of the fetus for exchange transfusion following 35 wk GA

Complications
- anti-Rh IgG can cross the placenta and cause fetal RBC hemolysis resulting in fetal anemia, CHF, edema, ascites
- severe cases can lead to hydrops fetalis (edema in at least two fetal compartments due to fetal heart failure secondary to anemia) or erythroblastosis fetalis (moderate to severe immune-mediated hemolytic anemia)

Fetal Surveillance

DDx of Decreased Fetal Movements

DASH
Death of fetus
Amniotic fluid decreased
Sleep cycle of fetus
Hunger/Thirst

- patients will generally first notice FM ("quickening") at 18-20 wk GA in primigravidas; can occur 1-2 wk earlier in multigravidas; can occur 1-2 wk later if placenta is implanted on the anterior wall of uterus
- if there is concern about decreased FM, the patient is counselled to choose a time when the fetus is normally active to count movements (usually recommended after 26 wk)
- all high-risk patients should be advised to do FM counts
  - should experience ≥6 perceived movements in 2 h period
  - if there is a subjective decrease in FM, time how long it takes to feel 10 discrete movements (laying on the left in a quiet setting may facilitate feeling subtle movements)
  - if 10 movements take more than 2 h, further assessment is indicated, and patient should present to labour and delivery triage for assessment

NON-STRESS TEST

Normal NST: 2 accels, >15 bpm from baseline, lasting >15 s in 20 min

Definition
- FHR tracing ≥20 min using an external Doppler to assess FHR and its relationship to FM (see Gynaecology, *First and Second Trimester Bleeding*, GY20)

Indication
- any suggestion of uteroplacental insufficiency or suspected compromise in fetal well-being

Table 5. Classification of Intrapartum EFM Tracings

	Normal Tracing (Category 1)	Atypical Tracing* (Category 2)	Abnormal Tracing* (Category 3)
Baseline	110-160 bpm	100-110 bpm or >160 bpm for 30-80 min Rising baseline Arrhythmia	Bradycardia <100 bpm Tachycardia >160 for >80 min Erratic baseline
Variability	6-25 bpm (moderate) ≤5 (absent or minimal) for <40 min	≤5 (absent or minimal) for 40-80 min	≤5 for >80 min ≥25 bpm for >10 min Sinusoidal
Decelerations	None Non-repetitive uncomplicated variable Early decelerations	Repetitive uncomplicated variables Non-repetitive complicated variables Intermittent late decelerations Single prolonged deceleration ≥2 min but <3 min	Repetitive complicated variables Recurrent late decelerations Single prolonged deceleration ≥3 min but <10 min
Acceleration	Spontaneous accelerations but not required Acceleration with scalp stimulation	Absence of acceleration with scalp stimulation	Usually absent (accelerations, if present, do not change classification of tracing)
Interpret Clinically	No evidence of fetal compromise	Physiologic response	Possible fetal compromise

Adapted from: SOGC, Fetal Health Surveillance: Intrapartum Consensus Guideline, March 2020

Describing NSTs: baseline rate, absent/minimal/moderate/marked variability, accelerations present/not present, decelerations early/late/variable

Reassuring BPP (8/8)

LAMB
Limb extension + flexion
AFV 2 cm x 2 cm
Movement (3 discrete)
Breathing (one episode x 30 s)

Operating Characteristics
- false positive rate depends on duration; false negative rate = 0.2-0.3%

Interpretation
- normal: >32 wk GA: at least 2 accelerations of FHR ≥15 bpm from the baseline lasting ≥15 s in 20 min
- normal: <32 wk GA: at least 2 accelerations of FHR ≥10 bpm from the baseline lasting ≥10 s in 20 min
- abnormal: <2 accelerations of FHR in 40 min
- if no observed accelerations or FM in the first 20 min, stimulate fetus (fundal pressure, acoustic/vibratory stimulation) and continue monitoring for 30 min

BIOPHYSICAL PROFILE

Definition
- U/S assessment of the fetus ± NST

Indications
- post-term pregnancy
- decreased FM
- IUGR
- any other suggestion of fetal distress or uteroplacental insufficiency

Table 6. Ultrasound Scoring Components of the BPP

Parameter	Reassuring (2 points)
Tone	At least one episode of limb extension followed by flexion
Movement	Three discrete movements
Breathing	At least one episode of breathing lasting at least 30 s
Amniotic Fluid Volume (AFV)*	Fluid pocket of 2 cm in 2 axes

*AFV is a marker of chronic hypoxia, all other parameters indicate acute hypoxia

Interpretation
- 8/10 with normal fluid or 10/10: perinatal mortality rate 1:1000; intervention for obstetric and maternal factors
- 6-8/10 with abnormal fluid: perinatal mortality rate 9:1000; determine that there is functioning renal tissue and intact membranes. If so, deliver fetus at term, continue surveillance of preterm fetus <34 wk GA to maximize fetal maturity
- 6/10 with normal fluid: perinatal mortality variable; equivocal test, repeat BPP in 24 h
- 0-4/10: perinatal mortality rate 91-600:1000; consider delivery for fetal indications

Counselling of the Pregnant Patient

Nutrition

- Canada's Food Guide to Healthy Eating suggests
  - eating a varied diet with plenty of vegetables and fruits, whole grains, dairy products, and lean meats or plant proteins
  - caloric increase of ~100 kCal/d in T1, ~300 kCal/d in T2 and T3, and ~450 kCal/d during lactation (less if BMI >25)
  - daily multivitamin with folic acid should be continued during pregnancy

Nutrients in Pregnancy

- folate: 0.4-1 mg daily in all women starting 2-3 mo pre-conception until 4-6 wk postpartum; 4 mg if high-risk for NTD starting at least 3 mo pre-conception until 12 wk GA, then continue 0.4-1 mg until 4-6 wk postpartum or as long as breastfeeding continues
  - supports increase in blood volume, growth of maternal and fetal tissue, and decrease in incidence of NTD
  - foods rich in folic acid include: spinach, lentils, chickpeas, asparagus, broccoli, peas, brussels sprouts, corn, and oranges
- calcium: 1200-1500 mg/d
  - maintains integrity of maternal bones, skeletal development of fetus, and breast milk production
- vitamin D: 1000 IU
  - promotes calcium absorption
- iron: 0.8 mg/d in T1, 4-5 mg/d in T2, and >6 mg/d in T3
  - supports maternal increase in blood cell mass, supports fetal and placental tissue
  - required amounts exceed normal body stores and typical intake, and therefore need supplemental iron
  - iron is the only known nutrient for which requirements during pregnancy cannot be met by diet alone (see *Iron and Folate Deficiency Anemia*, OB28)
- essential fatty acids – supports fetal neural and visual development
  - contained in vegetable oils, margarines, peanuts, and fatty fish

Caffeine

- diuretic and stimulant that readily crosses placenta
- less than 300 mg/d is considered safe
- relationship between caffeine and IUGR is unknown (ACOG)
- SOGC states 1-2 cups/d are safe during pregnancy

Sources of Caffeine
- 5 oz cup coffee: 40-180 mg
- 5 oz brewed tea: 20-90 mg
- 12 oz cola: 46 mg
- Red Bull®: 67 mg
- Dark chocolate bar: 10 mg
- 8 oz hot chocolate: 5 mg

Herbal Teas and Preparations

- not enough scientific information about safety of various herbs and herbal products to recommend their use during pregnancy
- some herbal teas can have toxic or pharmacological effects on the mother or fetus
- raspberry leaf tea often used at term to promote labour
- herbal teas considered safe in moderation (2-3 cups/d): citrus peel, ginger, lemon balm, linden flower (unless cardiac condition), orange peel, and rose hip

Foodborne Illnesses

- microbiological contamination of food may occur through cross-contamination and/or improper food handling
  - listeriosis (*Listeria monocytogenes*) and toxoplasmosis (*Toxoplasma gondii*) are of concern during pregnancy
  - avoid consumption of raw meats and fish, raw hotdogs, raw eggs, raw sprouts (especially alfalfa), and unpasteurized dairy products or juices
  - avoid unpasteurized soft cheeses, deli meats, smoked salmon, and pâtés as they may be sources of *Listeria*
- chemical contamination of food
  - current guideline for mercury of 0.5 ppm in fish is not considered harmful for the general population, including pregnant women
  - Health Canada advises pregnant women to limit consumption of top predator fish such as shark, swordfish, king mackerel, and tilefish

Lifestyle

- 150 min of moderate-intensity per wk; "talk test" = should be able to speak while exercising; avoid supine position after 20 wk GA
- absolute contraindications
  - ruptured membranes, PTL, hypertensive disorders of pregnancy, incompetent cervix, IUGR, multiple gestations (>3), placenta previa after 28 wk GA, persistent T2 or T3 bleeding, uncontrolled T1DM, uncontrolled thyroid disease, serious cardiovascular or respiratory disease, and other systemic disorders
  - relative contraindications
    - recurrent pregnancy loss, gestational HTN, history of spontaneous preterm birth, mild/moderate cardiovascular or respiratory disease, symptomatic anemia, malnutrition, eating disorder, twin pregnancy after 28 wk GA, and other significant medical conditions
- weight gain: optimal gain depends on pre-pregnancy BMI (varies from 6.8-18.2 kg)
- work: strenuous work, extended hours and shift work during pregnancy may be associated with greater risk of low birth weight, prematurity, and spontaneous abortion
- air travel acceptable in T2; airline cut off for travel is 36-38 wk GA depending on the airline, to avoid giving birth on the plane
- sexual intercourse: may continue, except in patients at risk for: spontaneous abortion, PTL, or placenta previa; breast stimulation may induce uterine activity, and is discouraged in high-risk patients near term
- smoking: assist/encourage to reduce or quit smoking (see Family Medicine, FM13)
  - increased risk of decreased birth weight, placenta previa/abruption, spontaneous abortion, PTL, and stillbirth
  - psychosocial interventions considered first-line, nicotine replacement therapy, and/or pharmacotherapy if counselling unsuccessful
  - lowest effective dose to minimize fetal exposure, intermittent dosage preparations preferred
  - limited safety data for bupropion and varenicline use during pregnancy
- alcohol: no amount of alcohol is safe in pregnancy; encourage abstinence from alcohol during pregnancy; alcohol increases incidence of spontaneous abortion, stillbirth, and congenital anomalies
  - fetal alcohol spectrum disorder (see Paediatrics, P29)
- cocaine: microcephaly, growth retardation, prematurity, and placental abruption
- cannabis: smoking associated with low birth weight infants
- biopsychosocial considerations: discuss adjustment to pregnancy (e.g. mood, work, stress, family) and birth plan, refer to counselling or community resources as necessary

Weight Gain in Pregnancy

BMI	Total Gain in T2 & T3	Weekly Gain
<18.5	28-40 lb	1-1.3 lb/wk
18.5-24.9	25-35 lb	1 lb/wk
>25-29.9	15-25 lb	0.5-0.7 lb/wk
>30	11-20 lb	0.4-0.6 lb/wk

Medications

- most drugs cross the placenta to some extent
- very few drugs are teratogenic, but very few drugs have proven safety in pregnancy
- use any drug with caution and only if necessary
- analgesics: acetaminophen preferable to ASA or ibuprofen

Table 7. Documented Adverse Effects, Weigh Benefits vs. Risks, and Consider Medication Change

Contraindicated Medication	Adverse Effect
ACE Inhibitor	Fetal renal defects, IUGR, oligohydramnios
Carbamazepine	ONTD in 1-2%
Chloramphenicol	Grey baby syndrome (fetal circulatory collapse 2° to toxic accumulation)
Lithium	Ebstein's cardiac anomaly, goitre, hyponatremia
Misoprostol	Mobius syndrome (congenital facial paralysis with or without limb defects), spontaneous abortion, PTL
NSAIDs	Premature closure of the ductus arteriosus after 30 wk GA (prior to that, indomethacin used for tocolysis)
Phenytoin	Fetal hydantoin syndrome in 5-10% (IUGR, mental retardation, facial dysmorphogenesis, congenital anomalies)
Retinoids (e.g. Accutane®)	CNS, craniofacial, cardiac, and thymic anomalies
Sulpha drugs	Anti-folate properties, therefore theoretical risk in T1; risk of kernicterus in T3
Tetracycline	Stains infant's teeth, may affect long bone development
Valproate	Congenital malformation (including ONTD) up to 9%
Warfarin	Increased incidence of spontaneous abortion, stillbirth, prematurity, IUGR, fetal warfarin syndrome (nasal hypoplasia, epiphyseal stippling, optic atrophy, mental retardation, intracranial hemorrhage)

Drug Resources During Pregnancy and Breastfeeding

- Hale T. Medications and mothers' milk, 18th ed. Springer Publishing Company, 2019
- Lactmed: https://toxnet.nlm.nih.gov/newtoxnet/lactmed.htm

Immunizations

Intrapartum
- administration is dependent on the risk of infection vs. risk of immunization complications
- safe: tetanus toxoid, diphtheria, influenza, hepatitis B, and pertussis
- avoid live vaccines (risk of placental and fetal infection): polio, measles/mumps/rubella, and varicella
- contraindicated: oral typhoid
- the Public Health Agency of Canada recommends:
  - all pregnant women receive the influenza vaccine
  - all pregnant women should be given Tdap every pregnancy irrespective of immunization history. Ideally between 27-32 wk GA but can be given at 13-26 wk GA if high-risk of PTL

Postpartum
- rubella vaccine for all non-immune mothers. If they have had an adult booster and remain non-immune, they should not be revaccinated and pregnancy should be deferred for at least 1 mo following vaccination
- hepatitis B vaccine should be given to infants within 12 h of birth if maternal status unknown or positive or if father is known to have chronic hepatitis B infection – follow-up doses at 1 and 6 mo
- any vaccine required/recommended is generally safe postpartum

Radiation

- ionizing radiation exposure is considered teratogenic at high doses
  - if indicated for maternal health, should be done
- imaging not involving direct abdominal/pelvic high dosage radiation is not associated with adverse effects
  - higher dosage to fetus: plain x-ray of lumbar spine/abdomen/pelvis, barium enema, CT abdomen/pelvis/lumbar spine
- radioactive isotopes of iodine are contraindicated
- no known adverse effects from U/S or MRI (long-term effects of gadolinium unknown, avoid if possible)

Table 8. Approximate Fetal Doses from Common Diagnostic Procedures

Examination	Estimated Fetal Dose (cGy)	Number of Exams Safe in Pregnancy
Plain Film		
Abdomen	0-14	35
Pelvis	0-11	45
Lumbar spine	0-17	29
Thoracic spine	0.009	555
Chest (2 views)	<0.001	5000
CT		
Abdomen	0-8	6
Pelvis	2-5	2
Lumbar spine	0-24	20
Chest	0.006	833

Adapted from: Cohen-Kerem, et al. 2005 and Valentin 2000

Radiation in Pregnancy
- Necessary amount to cause miscarriage: >5 cGy
- Necessary amount to cause malformations: >20-30 cGy

Antepartum Hemorrhage

- see Gynaecology, *First and Second Trimester Bleeding*, GY20

Definition
- vaginal bleeding from 20 wk to term

Differential Diagnosis
- bloody show (represents cervical changes/early stages of dilation) – most common etiology in T3
- placenta previa
- placental abruption – most common pathological etiology in T3
- vasa previa
- cervical lesion (cervicitis, polyp, ectropion, cervical cancer)
- uterine rupture
- other: bleeding from bowel or bladder, abnormal coagulation

Table 9. Comparison of Placenta Previa and Abruptio Placentae

	Placenta Previa	Abruptio Placentae
Definition	Abnormal location of the placenta near, partially, or completely over the internal cervical os	Premature separation of a normally implanted placenta after 20 wk GA
Etiology	Idiopathic	Idiopathic
Epidemiology	0.5-0.8% of all pregnancies	1-2% of all pregnancies
Risk Factors	History of placenta previa (4-8% recurrence risk) Multiparity Increased maternal age Multiple gestation Uterine tumour (e.g. fibroids) or other uterine anomalies Uterine scar due to previous abortion, CD, D&C, myomectomy	Previous abruption (recurrence rate 5-16%) Maternal HTN (chronic or gestational HTN in 50% of abruptions) or vascular disease Cigarette smoking (>1 pack/d), excessive alcohol consumption, cocaine Multiparity and/or maternal age >35 yr PPROM Rapid decompression of a distended uterus (polyhydramnios, multiple gestation) Uterine anomaly, fibroids Trauma (e.g. motor vehicle collision, maternal battery)
Bleeding	PAINLESS	Usually PAINFUL

Placenta Previa

Definition

- placenta implanted in the lower segment of the uterus
- placental location is described in relation to the internal os as "mm away" or "mm of overlap"

Clinical Features

- PAINLESS bright red vaginal bleeding (recurrent), may be minimized and cease spontaneously but can become catastrophic
- mean onset of bleeding is 30 wk GA, but onset depends on degree of previa
- physical exam
  - do not perform digital vaginal exam until ruled out placenta previa (speculum and transvaginal probe are safe)
  - uterus soft and non-tender
  - presenting fetal part high or displaced
  - FHR usually normal
  - shock/anemia correspond to degree of apparent blood loss
- complications
  - fetal
    - perinatal mortality low but still higher than with a normal pregnancy
    - prematurity (bleeding often dictates early CD)
    - intrauterine hypoxia (acute or IUGR)
    - fetal malpresentation
    - PPROM
    - risk of fetal blood loss from placenta, especially if incised during CD
  - maternal
    - <1% maternal mortality
    - hemorrhage and hypovolemic shock, anemia, acute renal failure, and pituitary necrosis (Sheehan syndrome)
    - placenta accreta – especially if previous uterine surgery or anterior placenta previa
    - hysterectomy

Do NOT perform a vaginal exam until placenta previa has been ruled out by U/S

Investigations

- transvaginal U/S is more accurate than transabdominal U/S at diagnosing placenta previa at any GA
- spontaneously resolution is likely with increasing uterine distention if the placenta covers the internal os by <20 mm at 20 wk GA
- transvaginal U/S should be repeated in T3 as continued change in the placental location is likely

Management

- goal: keep pregnancy intrauterine until the risk of continuing pregnancy outweighs the risk of preterm delivery
- stabilize and monitor
  - maternal stabilization: large bore IV with hydration, O_2 for hypotensive patients
  - maternal monitoring: vitals, urine output, blood loss, blood work (hematocrit, CBC, INR/PTT, fibrinogen, FDP, type, and crossmatch)
  - electronic fetal monitoring
  - U/S assessment: when fetal and maternal conditions permit, determine fetal viability, GA, and placental location

- Rhogam® if mother is Rh-negative
- Kleihauer-Betke test to determine extent of fetomaternal transfusion and administer Rhogam® at adequate dose
- <37 wk GA and minimal bleeding: expectant management
  - admit to hospital
  - limited physical activity, no douches, enemas, or sexual intercourse
  - consider corticosteroids for fetal lung maturity
  - delivery when fetus is mature or hemorrhage indicating maternal or fetal compromise
- ≥37 wk GA: deliver by CD

Placental Abruption

Definition
- partial or total placental detachment that is premature and caused by bleeding at the decidual-placental interface
- occurs >20 wk GA (placental detachment <20 wk GA is classified as an abortion)

Clinical Features
- classification
  - total (fetal death inevitable) vs. partial
  - external/revealed/apparent: blood dissects downward toward cervix
  - internal/concealed/occult (20%): blood dissects upward toward fetus, may or may not present with vaginal bleeding
  - most are mixed
- presentation
  - usually PAINFUL (80%) vaginal bleeding (bleeding not always present if abruption is concealed), uterine tenderness, uterine contractions/hypertonus (lack of relaxation between contractions)
  - pain: sudden onset, constant, localized to lower back and uterus
  - shock/anemia out of proportion to apparent blood loss
  - ± fetal distress, fetal demise (15% present with demise), bloody amniotic fluid (fetal presentation typically normal)
  - ± coagulopathy

Placental abruption is the most common cause of DIC in pregnancy

Complications
- fetal complications: perinatal mortality 25-60%, prematurity, intrauterine hypoxia
- maternal complications: <1% maternal mortality, DIC (in 20% of abruptions), acute renal failure, anemia, hemorrhagic shock, pituitary necrosis (Sheehan syndrome), amniotic fluid embolus

Investigations
- clinical diagnosis, U/S not sensitive for diagnosing abruption (sensitivity 15%)

Management
- maternal stabilization: large bore IV with hydration, O_2 for hypotensive patients
- maternal monitoring: vitals, urine output, blood loss, blood work (hematocrit, CBC, PTT/PT, fibrinogen, FDP, type, and crossmatch)
- EFM
- blood products on hand (red cells, platelets, cryoprecipitate) because of DIC risk
- Rhogam® if Rh negative
  - Kleihauer-Betke test to assess dosing of Rhogam®, may confirm abruption (not diagnostic)
- abruption without fetal/maternal compromise (mild abruption)
  - <37 wk GA: use serial hematocrit to assess concealed bleeding, deliver when fetus is mature or when hemorrhage dictates
  - ≥37 wk GA: stabilize and deliver
- abruption with fetal/maternal compromise (moderate to severe abruption)
  - hydrate and restore blood loss and correct coagulation defect if present
  - vaginal delivery if no contraindication and no evidence of fetal or maternal distress
  - CD if live fetus and fetal or maternal distress develops with fluid/blood replacement, labour fails to progress, or if vaginal delivery otherwise contraindicated

Kleihauer-Betke Test
Quantifies fetal cells in the maternal circulation

Vasa Previa

Definition
- unprotected fetal vessels pass over the cervical os; associated with velamentous insertion of cord into membranes of placenta or succenturiate (accessory) lobe

Epidemiology
- 1 in 5000 deliveries – higher in twin pregnancies

Clinical Features
- PAINLESS vaginal bleeding and fetal distress (tachy-to-bradyarrhythmia in a sinusoidal pattern)
- if undiagnosed, 50% perinatal mortality, increasing to 75% if membranes rupture (most infants die of exsanguination)
- if diagnosed antenatally on U/S without labour or symptoms, then 97% survival

Investigations
- Apt test (NaOH mixed with the blood) can be done immediately to determine if the source of bleeding is fetal (supernatant turns pink) or maternal (supernatant turns yellow)
- Wright's stain on blood smear and look for nucleated red blood cells (in cord, not maternal blood)

Management
- planned CD (35-36 wk GA) or if bleeding, emergency CD (since bleeding is from fetus, a small amount of blood loss can have catastrophic consequences)

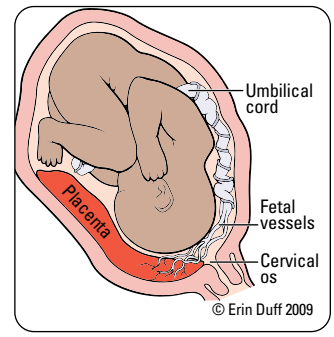

Figure 3. Vasa previa

Obstetrical Complications

Preterm Labour

Definition
- labour between 20 and 37 wk GA

Etiology
- idiopathic (most common)
- maternal: infection (recurrent pyelonephritis, untreated bacteriuria, chorioamnionitis), HTN, DM, chronic illness, mechanical factors (previous obstetric, gynaecological, and abdominal surgeries); socio-environmental (poor nutrition, smoking, drugs, alcohol, stress), preeclampsia, advanced reproductive age
- maternal-fetal: PPROM (common), polyhydramnios, placenta previa, placental abruption, placental insufficiency
- fetal: multiple gestation, congenital abnormalities, fetal hydrops
- uterine: excessive enlargement (hydramnios, multiple gestation), malformations (intracavitary leiomyomas, septate uterus, and Müllerian duct abnormalities)

Epidemiology
- PTL complicates about 10% of pregnancies

Risk Factors
- prior history of spontaneous PTL is the most important risk factor
- prior history of large or multiple cervical excisions (cone biopsy) or mechanical dilatation (D&C)
- cervical length: measured by transvaginal U/S (cervical length >30 mm has high negative predictive value for PTL before 34 wk GA)
- identification of bacterial vaginosis and *Ureaplasma urealyticum* infections
  - routine screening not supported by current data, but it is reasonable to screen high-risk women
- family history of preterm birth
- smoking
- late maternal age
- multiple gestation

Prevention of Preterm Labour
A. Cervical Cerclage
- definition: placement of cervical sutures at the level of the internal os, usually at the end of the T1 or in the T2 and removed in the T3
- indications: cervical incompetence (i.e. cervical dilation and effacement in the absence of increased uterine contractility)

PTL is the most common cause of neonatal mortality in the United States

Positive fetal fibronectin in cervicovaginal fluid (>50 ng/mL) at 24 wk GA predicted spontaneous PTL at <34 wk GA with sensitivity 23%, specificity 97%, PPV 25%, NPV 96%

Ultrasonographic Cervical Length Assessment in Predicting Preterm Birth in Singleton Pregnancies
J Obstet Gynaecol Can 2018;40(2);154-161
Recommendations:
1. Transabdominal ultrasonography should not be used for cervical length assessment to predict preterm birth (II-2D).
2. Transvaginal ultrasonography is the preferred route for cervical assessment to identify women at increased risk of spontaneous preterm birth and may be offered to women at increased risk of preterm birth (II-2B).
3. Transperineal ultrasonography may be offered to women at increased risk of preterm birth if transvaginal ultrasonography is either unacceptable or unavailable (II-2B).
4. Because of poor positive predictive values and sensitivities and lack of proven effective interventions, routine transvaginal cervical length assessment is not recommended in women at low-risk (II-2E).
5. In women presenting with suspected PTL, transvaginal sonographic assessment of cervical length may be used to help in determining who is at high-risk of preterm delivery and may be helpful in preventing unnecessary intervention. It is unclear whether this information results in a reduced risk of preterm birth (II-2B).
6. In asymptomatic women with a history of spontaneous preterm birth and an ultrasonographically diagnosed short cervical length (<25 mm) prior to 24 wk GA, cervical cerclage should be considered to reduce the risk of preterm birth (I-B).
7. In all asymptomatic women who present with membranes at or protruding past the external cervical os, an emergency cerclage should be considered to reduce the risk of preterm delivery (I-B).

- diagnosis of cervical incompetence
  - obstetrical Hx: silent cervical dilation, recurrent T2 losses, cervical procedures such as loop excisions
  - ability of cervix to hold an inflated Foley catheter during a hysterosonogram
  - transvaginal U/S of cervical length is recommended only for high-risk pregnancies and only before 28 wk GA
- proven benefit in the prevention of PTL in women with primary structural abnormality of the cervix (e.g. conization of the cervix, connective tissue disorders)

B. Progesterone
- progesterone thought to maintain uterine quiescence; however, exact mechanism of action is unclear
- if short cervix: 200 mg vaginally once daily from time of diagnosis to 36 wk GA
- superior to cerclage in preventing PTL of singletons not due to cervical incompetence

C. Lifestyle Modification
- smoking cessation, substance use reduction, treatment of GU infections (including asymptomatic UTIs), and patient education regarding risk factors

Predicting Preterm Labour
- fetal fibronectin: a glycoprotein in amniotic fluid and placental tissue
  - positive if >50 ng/mL; NPV > PPV
  - done if one or more signs of PTL (regular contractions >6/h, pelvic pressure, low abdominal pain and/or cramps, low backache)
  - done only if: 24-34 wk GA, intact membranes, <3 cm dilated, established fetal well being
  - contraindicated if: cerclage, active vaginal bleeding, vaginal exam, or sex in last 24 h
  - if negative, not likely to deliver in 7-14 d (>95% accuracy); if positive, increased risk of delivery, may need admission/transfer to centre that can do delivery ± tocolysis and/or corticosteroids

Clinical Features
- regular contractions (2 in 10 min, >6/h)
- cervix >1 cm dilated, >80% effaced, or length <2.5 cm

Management
A. Initial
- transfer to appropriate facility if stable
  - tocolysis and first dose of antenatal steroids prior to transfer
- hydration (normal saline at 150 mL/h)
- bed rest in left lateral decubitus position to reduce aortocaval compression and improve cardiac output
- analgesia (morphine)
- avoid repeated pelvic exams (increased infection risk)
- U/S examination of fetus (GA, BPP, presentation, placenta location, estimated fetal weight)
- prophylactic antibiotics (for GBS); important to consider if PPROM (e.g. erythromycin controversial, but may help to delay delivery)

B. Tocolysis (Suppression of Labour)
- does not inhibit PTL completely, but may delay delivery (used for <48 h) to allow for betamethasone valerate (Celestone®) and/or transfer to appropriate centre for care of the premature infant
- requirements (all must be satisfied)
  - PTL
  - live, immature fetus, intact membranes, cervical dilatation of <4 cm
- absence of maternal or fetal contraindications
- contraindications
  - maternal: bleeding (placenta previa or abruption), maternal disease (HTN, DM, heart disease), preeclampsia or eclampsia, chorioamnionitis
  - fetal: erythroblastosis fetalis, severe congenital anomalies, fetal distress/demise, IUGR, multiple gestation (relative)
- agents
  - calcium channel blockers: nifedipine
    - 20 mg PO loading dose followed by 20 mg PO 90 min later
    - 20 mg can be continued q3-8 h for 72 h or to a maximum of 180 mg
    - 10 mg PO q20 min x 4 doses
    - relative contraindications: nifedipine allergy, hypotension, hepatic dysfunction, concurrent β-mimetics or magnesium sulfate use, transdermal nitrates, or other antihypertensive medications
    - absolute contraindications: maternal CHF, aortic stenosis
  - prostaglandin synthesis inhibitors: indomethacin
    - first-line for early PTL (<32 wk GA) or polyhydramnios
    - 50-100 mg PR loading dose followed by 25-50 mg q6 h x 8 doses for 48 h

Physical Examination-Indicated Cerclage: A Systematic Review and Meta-Analysis
Obstet Gynecol 2017;126:125-135
Purpose: To estimate the effectiveness of physical examination-indicated cerclage in the setting of T2 cervical dilatation
Methods: Meta-analysis of studies identified on MEDLINE, EMBASE, Scopus, ClinicalTrials.gov, Web of Science, and the Cochrane Library
Results: 10 trials, 757 women (485 underwent cerclage and 272 were expectantly managed). Studies compared cerclage with no cerclage in women with a physical examination that revealed cervical dilatation of ≥0.5 cm between 14 and 27 wk GA. Survival was more likely in the cerclage group (71%) compared to the expectantly managed group (47%) (RR=1.65, 95% CI 1.19-2.28). Cerclage was also associated with a significant prolongation of pregnancy (average 33.98 days, 95% CI 17.88-50.08), greater GA at delivery (mean difference 4.62 wk, 95% CI 3.89-5.36) and significant reductions in preterm birth between 24 and 28 wk GA (8% compared to 37%; RR=0.23, 95% CI 0.13-0.41) and at less than 34 wk GA (50% compared to 82%; RR=0.55, 95% CI 0.38-0.80)
Conclusions: Physical examination-indicated cerclage is associated with significant reductions in perinatal mortality and preterm birth. RCTs are warranted for additional investigation

Tocolytics for Preterm Premature Rupture of Membranes
Cochrane DB Syst Rev 2014;2:CD007062
Purpose: To assess the potential benefits and harms of tocolysis in women with PPROM.
Selection Criteria: Pregnant women with singleton pregnancies and PPROM (23-36+6 wk GA).
Results: 8 studies with 408 women total. Prophylactic tocolysis with PPROM was associated with increased overall latency, without additional benefits for maternal/neonatal outcomes. For women with PPROM before 34 wk GA, there was a significantly increased risk of chorioamnionitis in women who received tocolysis. Neonatal outcomes were not significantly different.
Conclusions: Although there are limitations to the studies, there is currently insufficient evidence to support tocolytic therapy for women with PPROM, as there was an increase in maternal chorioamnionitis without significant benefits to the infant.

C. Antenatal Corticosteroids
- betamethasone valerate (Celestone®) 12 mg IM q24 h x 2 doses or dexamethasone 6 mg IM q12 h x 4 doses
  - given between 24 to 34+6 wk GA if expected to deliver in the next 7 d
  - patients between 22+0 and 23+6 wk GA at high-risk of preterm birth within the next 7 d should be provided with multidisciplinary consultation regarding high likelihood for severe perinatal morbidity and mortality and associated maternal morbidity – consider antenatal corticosteroid therapy if early intensive care is requested and planned
  - specific maternal contraindications: active TB
- enhance fetal lung maturity, reduce perinatal death, reduce incidence of severe RDS, IVH, necrotizing enterocolitis, neonatal sepsis

D. Neuroprotection
- $MgSO_4$ 4 g bolus followed by 1 g/h infusion for at least 4 h if imminent delivery expected and ≤33+6 wk GA

Prognosis
- prematurity is the leading cause of perinatal morbidity and mortality
- 24 wk GA = 50% survival (may be higher in tertiary care centres with level 3-4 NICU)
- 30 wk GA or 1500 g (3.3 lb) = 90% survival
- 33 wk GA or 2000 g (4.4 lb) = 99% survival
- morbidity due to asphyxia, hypoxia, sepsis, RDS, IVH, thermal instability, retinopathy of prematurity, bronchopulmonary dysplasia, necrotizing enterocolitis

Prematurity increases newborn risk of:
- Respiratory distress
- Hypoglycemia
- Hyperbilirubinemia
- Apnea
- Feeding difficulties
- Seizures
- And more

Prelabour Rupture of Membranes

Definitions
- PROM: prelabour rupture of membranes at any GA
- prolonged ROM: >24 h elapsed between rupture of membranes and onset of labour
- PPROM: preterm (before 37 wk GA) AND PROM

Risk Factors
- maternal: multiparity, cervical incompetence, infection (cervicitis, vaginitis, STI, UTI), family history of PROM, low socioeconomic class/poor nutrition
- fetal: congenital anomaly, multiple gestation
- other risk factors associated with PTL

Clinical Features
- history of fluid gush or continued leakage

Investigations
- sterile speculum exam (avoid introduction of infection)
  - pooling of fluid in the posterior fornix
  - cascading: fluid leaking out of cervix with cough/valsalva
- nitrazine (basic amniotic fluid turns nitrazine paper blue)
  - low specificity as it can also be positive with blood, urine, or semen
- ferning: salt in amniotic fluid evaporates, giving amniotic fluid the appearance of ferns on microscopy
- U/S to rule out fetal anomalies; assess GA, presentation, and BPP

Membrane status determined by
- Pooling of fluid on speculum exam
- Increased pH of vaginal fluid (nitrazine test)
- Ferning of fluid under light microscopy
- Decreased AFV on U/S

Management
- admit for expectant management and monitor vitals q4 h, daily NST, WBC count, surveillance for infection
- avoid introducing infection by minimizing examinations
  - consider administration of betamethasone valerate (Celestone®) to accelerate maturity if <35 wk GA if no evidence of infection
  - consider tocolysis for 48 h to permit administration of steroids if PPROM induces labour
- screen patients for UTIs, STIs, GBS infection and treat with appropriate antibiotics if positive (treat GBS at time of labour)
- if not in labour or labour not indicated, consider antibiotics: penicillins or macrolide antibiotics are the antibiotics of choice
- deliver urgently if evidence of fetal distress and/or chorioamnionitis

Antibiotic Therapy in Preterm Premature Rupture of the Membranes
J Obstet Gynaecol Can 2017;39(9):207-212
Recommendations:
1. Following PPROM, antibiotics should be administered to women who are not in labour in order to prolong pregnancy and to decrease maternal and neonatal morbidity
2. The benefit of antibiotics is greater at earlier GAs
3. Antibiotics of choice are penicillins or macrolide antibiotics (erythromycin) in parenteral and/or oral forms. In patients allergic to penicillin, macrolide antibiotics should be used alone
4. Two possible regimen options from large PPROM RCTs are: (1) ampicillin 2 g IV q6 h and erythromycin 250 mg IV q6 h for 48 h followed by amoxicillin 250 mg PO q8 h and erythromycin 333 mg PO q8 h for 5 d; (2) erythromycin 250 mg PO q6 h for 10 d
5. Amoxicillin/clavulanic acid should not be used because of an increased risk of necrotizing enterocolitis in neonates. Amoxicillin without clavulanic acid is safe
6. Women presenting with PPROM should be screened for UTIs, STIs, and GBS

Table 10. PROM Management

Gestational Age	Management
22-25 wk	Individual consideration with counselling of parents regarding risks to preterm infants
26-34 wk	Expectant management as prematurity complications are significant
34-36 wk	"Grey zone" where risk of death from RDS and neonatal sepsis is the same
≥37 wk	Induction of labour since the risk of death from sepsis is greater than RDS

Prognosis
- varies with gestational age
- 90% of patients with PROM at 28-34 wk GA go into spontaneous labour within 1 wk
- 50% of patients with PROM at <26 wk GA go into spontaneous labour within 1 wk
- complications: cord prolapse, intrauterine infection (chorioamnionitis), premature delivery, limb contracture, and pulmonary hypoplasia especially at very early GA

Post-term Pregnancy

Definition
- pregnancy >42 wk GA

Epidemiology
- 41 wk GA: up to 27%
- >42 wk GA: 5.5%

Etiology
- most cases are idiopathic
- anencephalic fetus with no pituitary gland
- placental sulfatase deficiency (X-linked recessive condition, incidence ranges from 1 in 2000 to 1 in 6000 births)
- incorrect dates

Management (for singleton, cephalic fetus, otherwise uncomplicated)
- labour induction is recommended at 41+3 wk GA if no contraindications to vaginal delivery (see *Induction and Augmentation of Labour*, OB38)

Prognosis
- if >42 wk GA, perinatal mortality 2-3x higher (due to progressive uteroplacental insufficiency)
- with increasing GA, higher rates of: intrauterine infection, asphyxia, meconium aspiration syndrome, placental insufficiency, placental aging and infarction, macrosomia, dystocia, fetal distress, operative deliveries, pneumonia, seizures, NICU admission, stillbirth
- morbidity increased with HTN in pregnancy, DM, placental abruption, IUGR, advanced reproductive age, and multiple gestation

Intrauterine Fetal Death

Definition
- fetal demise *in utero* after 20 wk GA (before 20 wk GA called spontaneous abortion)

Epidemiology
- occurring in 1% of pregnancies, increased in high-risk pregnancies

Etiology
- 50% idiopathic
- 50% secondary to HTN, DM, erythroblastosis fetalis, congenital anomalies, umbilical cord or placental complications, intrauterine infection, and APS

Clinical Features
- decreased perception of FM by mother
- SFH and maternal weight not increasing
- absent fetal heart tones on Doppler (not diagnostic)
- high MSAFP
- on U/S: no FHR. Depending on timing of death, may see skull collapse, brain tissue retraction, empty fetal bladder, non-filled aorta, or poor visualization of midline falx

Management
- diagnosis: absent cardiac activity and FM on U/S (required)
- determine secondary cause
  - maternal: HbA1c, fasting glucose, TSH, Kleihauer-Betke, VDRL, ANA, CBC, anticardiolipins, antibody screens, INR/PTT, serum/urine toxicology screens, cervical and vaginal cultures, and TORCH screen
  - fetal: karyotype, cord blood, skin biopsy, genetics evaluation, autopsy, amniotic fluid culture for CMV, parvovirus B19, and herpes
  - placenta: pathology, bacterial cultures

DIC: Generalized Coagulation and Fibrinolysis Leading to Depletion of Coagulation Factors

Obstetrical Causes
- Placental abruption
- Gestational HTN
- Fetal demise
- PPH

DIC-specific Blood Work
- CBC (platelets)
- aPTT and PT
- FDP
- Fibrinogen

Treatment
- Treat underlying cause
- Supportive
- Fluids
- Blood products
- FFP, platelets, cryoprecipitate
- Consider anti-coagulation as VTE prophylaxis

Treatment
- >20 wk GA: IOL
- monitor for maternal coagulopathy (10% risk of DIC)
- parental psychological care/bereavement support as per hospital protocol
- comprehensive discussion within 3 mo about final investigation and post-mortem results, help make plans for future pregnancies

Intrauterine Growth Restriction

Definition
- estimated fetal weight <10th percentile for GA on U/S, has not reached biologically determined growth potential

Etiology/Risk Factors
- 50% unknown
- maternal causes
  - malnutrition, smoking, drug misuse, alcoholism, cyanotic heart disease, T1DM, SLE, pulmonary insufficiency, previous IUGR (25% risk, most important risk factor), chronic HTN, gestational HTN, chronic renal insufficiency, prolonged gestation, substance misuse, and poor nutrition
- placental
  - any disease that causes placental insufficiency
  - gross placental morphological abnormalities (infarction, hemangiomas, placenta previa, and abnormal cord insertion)
- fetal causes
  - TORCH infections, multiple gestation, and congenital anomalies/chromosomal abnormalities (10%)

TORCH
Toxoplasmosis
Others: e.g. syphilis
Rubella
CMV
HSV
See Table 15, OB31

Clinical Features
- symmetric/type I (25-30%): occurs early in pregnancy
  - reduced growth of both head and abdomen
  - head:abdomen ratio may be normal (>1 up to 32 wk GA; =1 at 32-34 wk GA; <1 after 34 wk GA)
  - usually associated with congenital anomalies or TORCH infections
- asymmetric/type II (70%): occurs late in pregnancy
  - fetal abdomen is disproportionately smaller than fetal head
  - brain is spared; therefore head:abdomen ratio increased
  - usually associated with placental insufficiency
  - more favourable prognosis than type I
- complications
  - prone to meconium aspiration, asphyxia, polycythemia, hypoglycemia, hypocalcemia, hypophosphatemia, hyponatremia, and intellectual disability
  - greater risk of perinatal morbidity and mortality

Investigations
- SFH measurements at every antepartum visit (ensure accurate GA)
- if mother at high-risk or SFH lags >2 cm behind GA
  - U/S for biparietal diameter, head and abdominal circumference ratio, FL, fetal weight, AFV (decrease associated with IUGR), and decrease in the rate of growth
  - ± BPP
  - Doppler analysis of umbilical cord blood flow

Management
- prevention via risk modification prior to pregnancy is ideal
- modify controllable factors: smoking, alcohol, nutrition, and treat maternal illness
- serial BPP (monitor fetal growth) and determine cause of IUGR, if possible
- delivery when extrauterine existence is less dangerous than continued intrauterine existence (abnormal function tests, absent growth, severe oligohydramnios) especially if >34 wk GA
- optimize fetus with celestone, magnesium sulfate for neuroprotection, early GBS swab, and pediatrics consult if anticipated preterm delivery
- as IUGR fetuses are less likely to withstand stresses of labour, they are more likely to be delivered by CD

Macrosomia

Definition
- infant weight ≥90th percentile for a particular GA or >4000 g

Etiology/Risk Factors
- maternal obesity, gestational and pre-gestational DM, past history of macrosomic infant, prolonged gestation, multiparity, excessive maternal weight gain during pregnancy

Clinical Features
- increased risk of perinatal mortality
- CPD and birth injuries (shoulder dystocia, fetal bone fracture) more common
- complications of DM in labour (see Table 14, OB30)

Investigations
- serial SFH
- U/S for estimated fetal weight if mother at high-risk or SFH >2 cm ahead of GA

Management
- prevent hyperglycemia in patients with DM, optimize pre-pregnancy weight, and limit excessive pregnancy weight gain in patients with increased BMI
- planned CD is a reasonable option where EFW >5000 g in non-diabetic patients and EFW >4500 g in diabetic patients

Polyhydramnios/Oligohydramnios

Table 11. Polyhydramnios and Oligohydramnios

	Polyhydramnios	Oligohydramnios
Definition	AFI >25 cm U/S: single deepest pocket >8 cm	AFI <5 cm U/S: single deepest pocket ≤2 cm
Etiology	Idiopathic most common Maternal T1DM: abnormalities of transchorionic flow Maternal-fetal Chorioangiomas Multiple gestation Fetal hydrops (increased erythroblastosis) Fetal Chromosomal anomaly (up to 2/3 of fetuses have severe polyhydramnios) Respiratory: cystic adenomatoid malformed lung CNS: anencephaly, hydrocephalus, meningocele GI: tracheoesophageal fistula, duodenal atresia, facial clefts (interfere with swallowing)	Idiopathic most common Maternal Uteroplacental insufficiency (preeclampsia, nephropathy) Medications (ACEI) Fetal Congenital urinary tract anomalies (renal agenesis, obstruction, posterior urethral valves) Demise/chronic hypoxemia (blood shunt away from kidneys to perfuse brain) IUGR Ruptured membranes: prolonged amniotic fluid leak Amniotic fluid normally decreases after 35 wk GA
Epidemiology	Occurs in 0.2-1.6% of all pregnancies	Occurs in ~4.5% of all pregnancies Severe form in <0.7% Common in pregnancies >41 wk GA (~12%)
Clinical Features and Complications	Uterus large for GA, difficulty palpating fetal parts and hearing FHR Maternal complications Pressure symptoms from overdistended uterus (dyspnea, edema, hydronephrosis) Obstetrical complications Cord prolapse, placental abruption, malpresentation, PTL, uterine dysfunction, and PPH	Uterus small for dates Fetal complications 15-25% have fetal anomalies Amniotic fluid bands (T1) can lead to Potter's facies, limb deformities, abdominal wall defects Obstetrical complications Cord compression Increased risk of adverse fetal outcomes Pulmonary hypoplasia (late-onset) Marker for infants who may not tolerate labour well
Management	Determine underlying cause Screen for maternal disease/infection Complete fetal U/S evaluation Depends on severity Mild to moderate cases require no treatment If severe, hospitalize and consider therapeutic amniocentesis	Always warrants admission and investigation Rule out ROM Fetal monitoring (NST, BPP) U/S Doppler studies (umbilical cord and uterine artery) Maternal hydration with oral or IV fluids to help increase amniotic fluid Injection of fluid via amniocentesis will improve condition for ~1 wk – may be most helpful for visualizing any associated fetal anomalies Consider delivery if term Amnio-infusion may be considered during labour via intrauterine catheter
Prognosis	2- to 5-fold increase in risk of perinatal mortality	Poorer with early onset High mortality related to congenital malformations and pulmonary hypoplasia when diagnosed during T2

Antenatal Depression

Definition
- major depression occurring in a patient who is pregnant, onset may be prior to pregnancy

Epidemiology
- occurs in 7-9% of pregnancies

Risk Factors
- prior history of depression, anxiety, unintended or unwanted pregnancy, life stress, intimate partner violence or history of abuse, poor social support, chronic general medical conditions

Clinical Features
- comparable to symptoms of non-pregnant MDD (see Psychiatry, PS12)
- suspect if: prior history of depression, excessive anxiety about the fetus, poor self-esteem, despondency, anhedonia, non-adherence to antenatal care, poor weight gain due to decreased appetite or inadequate diet, suicidal ideation

Assessment
- Edinburgh Postnatal Depression Scale or others

Treatment
- antidepressants, psychotherapy, supportive care, and electroconvulsive therapy if refractory or if features of psychosis, catatonia, high risk suicide, and fluid or food refusal leading to dehydration and malnutrition

Prognosis
- may be associated with altered fetal physiologic effects, adverse pregnancy and neonatal outcomes, abnormal infant and child development, cognitive impairment and psychopathology in the offspring, leading to lasting long-term effects
- increased risk of recurrence after pregnancy, changed diagnosis to bipolar disorder

Multi-Fetal Gestation and Malpresentation

Epidemiology
- incidence of twins is 1 in 80 and triplets 1 in 6400 in North America
- 2/3 of twins are dizygotic (fraternal)
  - risk factors for dizygotic twins: IVF, increased maternal age, newly discontinued OCP, and ethnicity (e.g. certain African regions)
- monozygous twinning occurs at a constant rate worldwide (1 in 250)
- determine zygosity by number of placentas, thickness of membranes, sex, and blood type

The Ps of Multiple Gestation Complications

Increased rates of:
Puking
Pallor (anemia)
Preeclampsia/Pregnancy-induced HTN
Pressure (compressive symptoms)
PTL/**P**ROM/**P**PROM
Polyhydramnios
Placenta previa/abruption
PPH/ Antepartum hemorrhage
Prolonged labour
Cord **P**rolapse
Prematurity
Mal**p**resentation
Perinatal morbidity and mortality
Parental distress
Postpartum depression

Clinical Features

Table 12. Complications Associated with Multiple Gestation

Maternal	Uteroplacental	Fetal
Hyperemesis gravidarum	Increased PROM/PTL	Prematurity
GDM	Polyhydramnios	IUGR
Gestational HTN	Placenta previa	Malpresentation
Anemia	Placental abruption	Congenital anomalies
Increased physiological stress on all systems	PPH (uterine atony)	Twin-twin transfusion syndrome
Increased compressive symptoms	Umbilical cord prolapse	Increased perinatal morbidity and mortality
CD	Cord anomalies	Twin interlocking (twin A breech, twin B vertex)
Thrombosis	(velamentous insertion, 2 vessel cord)	Single fetal demise

Management
- U/S determination of chorionicity must be done within T1 (ideally 8-12 wk GA)
- increased antenatal surveillance
  - serial U/S q2-3 wk from 16 wk GA (monochorionic), q3-4 wk from 18-22 wk GA (uncomplicated diamniotic dichorionic) to assess growth
  - Doppler flow studies weekly if discordant fetal growth (>30%)
  - BPP
- may attempt vaginal delivery (if dichorionic diamniotic or monochorionic diamniotic) if twin A presents as vertex and growth discrepancy <25%, otherwise CD (40-50% of all twin deliveries, 10% of cases have twin A delivered vaginally and twin B delivered by CD)
- all monochorionic monoamniotic twins need to be delivered by CD
- mode of delivery depends on fetal weights, GA, and presentation

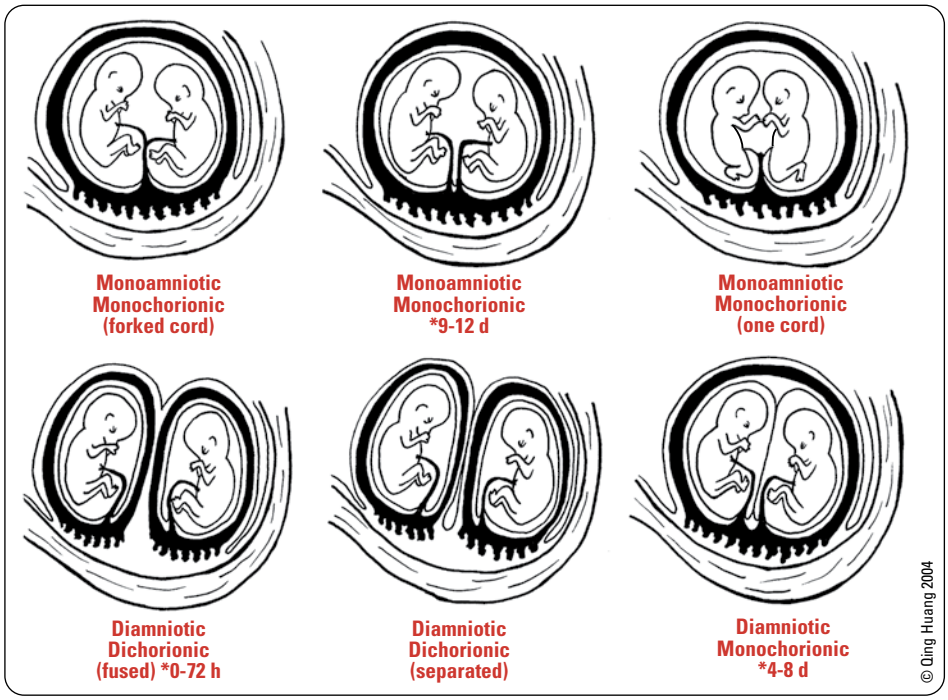

Figure 4. Classification of twin pregnancies
*Indicates time of cleavage

Twin-Twin Transfusion Syndrome

Definition
- formation of placental intertwin vascular anastomoses can cause arterial blood from donor twin to pass into veins of the recipient twin

Epidemiology
- 10% of monochorionic twins
- concern if >30% discordance in estimated fetal weight

Clinical Features
- donor twin: IUGR, hypovolemia, hypotension, anemia, and oligohydramnios
- recipient twin: hypervolemia, HTN, CHF, polycythemia, edema, polyhydramnios, and kernicterus in neonatal period

Investigations
- detected by U/S screening, Doppler flow analysis

Management
- fetoscopic laser ablation of placental vascular anastomoses (preferred between 16-26 wk GA)
- therapeutic serial amniocentesis to decompress polyhydramnios of recipient twin and decrease pressure in cavity and on placenta
- intrauterine blood transfusion to donor twin if necessary

Breech Presentation

Definition
- fetal buttocks or lower extremity is the presenting part as determined on U/S
- complete (10%): hips and knees both flexed
- frank (60%): hips flexed, knees extended, buttocks present at cervix
  - most common type of breech presentation
  - most common breech presentation to be delivered vaginally
- incomplete (30%): both or one hip partially flexed and both or one knee present below the buttocks, feet or knees present first (footling breech, kneeling breech)

Epidemiology
- occurs in 3-4% of pregnancies at term (25% at <28 wk GA)

Criteria for Vaginal Breech Delivery
- Frank or complete breech, >36 wk GA
- EFW 2500-3800 g based on clinical and U/S assessment (5.5-8.5 lb)
- Fetal head flexed
- Continuous fetal monitoring
- Two experienced obstetricians, assistant, and anesthetist present
- Ability to perform emergency CD within 30 min if required
- Mother motivated for vaginal breech delivery and understands risks and benefits

Risk Factors
- maternal: pelvis (contracted), uterus (shape abnormalities, fibroids, previous breech), pelvic tumours causing compression, and grand multiparity
- placental: placenta previa
- fetal: prematurity, amniotic fluid (poly-/oligohydramnios), multiple gestation, congenital malformations (found in 6% of breeches; 2-3% if in vertex presentations), abnormalities in fetal tone and movement, aneuploidy, hydrocephalus, and anencephaly

Management
- pre- or early-labour U/S to assess type of breech presentation, fetal growth, estimated weight, placenta position, attitude of fetal head (flexed is preferable); if U/S unavailable, recommend CD
- external cephalic version (ECV) and elective CD should be presented as options with the risks and benefits outlined; obtain informed consent
- **ECV**: repositioning of singleton fetus within uterus under U/S guidance
  - overall success rate of ~40-60%
  - criteria: >36 wk GA, singleton, unengaged presenting part, reactive NST, not in labour
  - contraindications
    - absolute: where CD is required (placenta previa, previous classical CD), previous myomectomy, PROM, uteroplacental insufficiency, nuchal cord, non-reactive NST, multiple gestation
    - relative: mild/moderate oligohydramnios, suspected IUGR, HTN, previous T3 bleed
  - risks: abruption, cord compression, cord accident, ROM, labour, fetal bradycardia requiring CD (<1% risk), alloimmunization, fetal death (1/5000)
  - method: tocometry, followed by U/S guided transabdominal manipulation of fetus with constant fetal heart monitoring
  - if patient Rh negative, give Rhogam® after the procedure
  - better prognosis if multiparous, good fluid volume, small baby, skilled obstetrician, and posterior placenta
  - if unsuccessful, planned vaginal breech birth or planned CD
- **vaginal breech delivery**: can be spontaneous or assisted
  - method:
    - encourage effective maternal pushing efforts
    - at delivery of head (after feet), assistant must apply suprapubic pressure to flex and engage fetal head
    - delivery can be spontaneous or assisted; avoid fetal traction
    - apply fetal manipulation only after spontaneous delivery to level of umbilicus
  - contraindications: cord presentation, fetal factors incompatible with vaginal delivery (e.g. hydrocephalus, macrosomia, fetal growth restriction), clinically inadequate maternal pelvis
- CD recommended if: the breech has not descended to the perineum in the second stage of labour after 2 h, in the absence of active pushing, or if vaginal delivery is not imminent after 1 h of active pushing

Prognosis
- regardless of route of delivery, breech infants have lower birth weights and higher rates of perinatal mortality, congenital anomalies, abruption, and cord prolapse

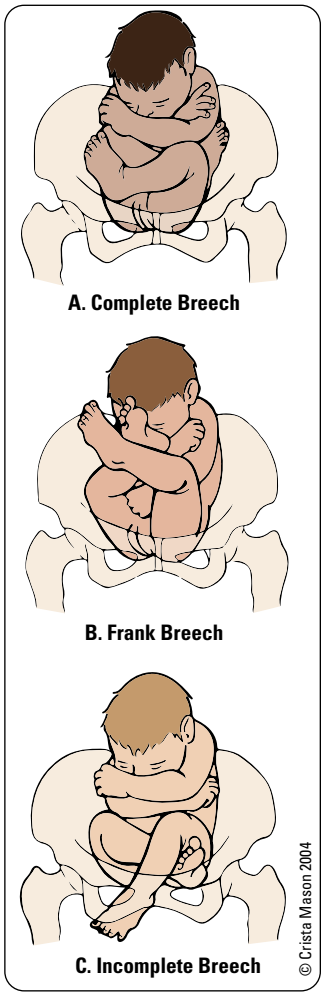

Figure 5. Types of breech presentation

Hypertensive Disorders of Pregnancy

Hypertension in Pregnancy

- hypertensive disorders of pregnancy are classified as either pre-existing or de novo (gestational HTN or pre-eclampsia) and exist on a spectrum

Ominous Symptoms of HTN in Pregnancy
Right upper quadrant pain, headache, and visual disturbances

PRE-EXISTING HYPERTENSION

Definition
- sBP ≥140 or dBP ≥90 prior to 20 wk GA; BP should be elevated on ≥2 occasions at least 15 min apart
- essential HTN is associated with an increased risk of gestational HTN, abruptio placentae, IUGR, and IUFD

GESTATIONAL HYPERTENSION

Definition
- sBP ≥140 or dBP ≥90 after 20 wk GA without proteinuria in a patient known to be normotensive before pregnancy

PREECLAMPSIA

Definition
- pre-existing or gestational HTN with new onset proteinuria (urinary protein/creatinine ratio >30 mg/mmol) or adverse conditions (end organ dysfunction)

ECLAMPSIA

Definition
- the occurrence of ≥1 generalized convulsions and/or coma in the setting of preeclampsia and in the absence of other neurologic conditions

Epidemiology of Eclampsia
- an eclamptic seizure occurs in approximately 0.5% of mildly preeclamptic patients and 2-3% of severely preeclamptic patients

Clinical Manifestation of Eclampsia
- eclampsia is a clinical diagnosis
- typically tonic-clonic and lasting 60-75 s
- symptoms that may occur before the seizure include persistent frontal or occipital headache, blurred vision, photophobia, right upper quadrant or epigastric pain, and altered mental status
- in up to one third of cases, there is no proteinuria or blood pressure ≥140/90 mmHg prior to the seizure
- in general, women with typical eclamptic seizures who do not have focal neurologic deficits or prolonged coma do not require diagnostic evaluation including imaging

Risk Factors for Hypertensive Disorders in Pregnancy
- maternal factors
  - primigravida (80-90% of gestational HTN), first conception with a new partner, PMHx or FMHx of gestational HTN, or preeclampsia/eclampsia
  - DM, chronic HTN, or renal insufficiency
  - obesity
  - antiphospholipid syndrome or inherited thrombophilia
  - extremes of maternal age (<18 or >35 yr)
  - previous stillbirth or IUFD
  - vascular or connective tissue disease
- fetal factors
  - IUGR or oligohydramnios
  - GTN
  - multiple gestation
  - fetal hydrops "mirror syndrome"
  - abruptio placentae

Clinical Evaluation of Hypertensive Disorders in Pregnancy
- in general, clinical evaluation should include the mother and fetus
- evaluation of mother:
  - body weight
  - central nervous system
    - presence and severity of headache
    - visual disturbances (blurring, scotomata)
    - tremulousness, irritability, and somnolence
    - hyperreflexia
  - hematologic (bleeding, petechiae)
  - hepatic (right upper quadrant or epigastric pain, severe N/V)
  - renal (urine output, colour)
- evaluation of fetus:
  - FM
  - FHR tracing – NST
  - U/S for growth
  - BPP
  - Doppler flow studies

Laboratory Evaluation of Hypertensive Disorders in Pregnancy
- CBC
- PTT, INR, fibrinogen – if abnormal LFTs or bleeding
- ALT, AST
- creatinine, uric acid
- 24 h urine collection for protein or albumin:creatinine ratio
- may consider placental growth factor (PlGF) testing as an early screening test for suspected preeclampsia

Eclampsia prior to 20 wk GA is rare and should raise the possibility of an underlying molar pregnancy or antiphospholipid syndrome

Hypertension in Pregnancy

Adverse Maternal Conditions
- sBP >160 mmHg
- dBP >100 mmHg
- HELLP
- Cerebral hemorrhage
- Renal dysfunction: oliguria <500 mL/d
- Left ventricular failure, pulmonary edema
- Placental abruption, DIC
- Symptoms
- Abdominal pain, N/V
- Headaches, visual problems
- SOB, chest pain
- Eclampsia: convulsions

Adverse Fetal Conditions
- IUGR
- Oligohydramnios
- Absent/reversed umbilical artery end diastolic flow
- **Can result in:**
  Fetal disability and/or death

I-A Evidence-Recommendation Highlights of SOGC Clinical Practice Guidelines
Diagnosis, Evaluation, and Management of the Hypertensive Disorders of Pregnancy
J Obstet Gynaecol Can 2014;36(5):416-438
- For BP measurement, Korotkoff phase V should be used to designate the dBP
- Calcium supplementation (of at least 1 g/d PO) is recommended for women with low dietary intake of calcium (<600 mg/d). (I-A)
- For preeclampsia prevention among increased risk women, low-dose ASA (75-100 mg/d) is recommended until delivery
- Umbilical artery Doppler velocimetry should be part of the antenatal fetal surveillance in preeclampsia
- Initial antihypertensive therapy for severe HTN (sBP ≥160 or dBP ≥110) should be with labetalol, nifedipine, or hydralazine
- Initial antihypertensive therapy for non-severe HTN (BP 140-159/90-109 mmHg) should be with methyldopa, β-blockers, or calcium channel blockers
- Antenatal corticosteroids for fetal lung maturation should be considered for all women with preeclampsia before 34 wk gestation
- In a planned vaginal delivery with an unfavourable cervix, cervical ripening should be used
- Oxytocin 5 units IV or 10 units IM should be used as part of the management during the third stage of labour, particularly in the presence of thrombocytopenia or coagulopathy
- Magnesium sulfate is the recommended first-line treatment for eclampsia
- Magnesium sulfate is the recommended eclampsia prophylaxis in severe preeclampsia

Complications of Hypertensive Disorders in Pregnancy

- maternal
  - liver and renal dysfunction
  - seizure - "eclampsia"
  - abruptio placentae
  - left ventricular failure/pulmonary edema
  - DIC (release of placental thromboplastin consumptive coagulopathy)
  - HELLP syndrome
  - hemorrhagic stroke (50% of deaths)
- fetal (secondary to placental insufficiency)
  - IUGR, prematurity, abruptio placentae, IUFD

HELLP Syndrome
Hemolysis
Elevated
Liver Enzymes
Low
Platelets

Management of Hypertension

- for non-severe HTN (BP 149-159/90-109 mmHg): target a BP of 130-155/80-105 mmHg in patient without comorbidities or <140/90 mmHg in patient with comorbidities
  - antihypertensive therapy for both pre-existing and gestational HTN: labetalol 100-400 mg PO BID-TID, nifedipine XL preparation 20-60 mg PO once daily, or α-methyldopa 250-500 mg PO BID-TID
- for severe HTN (BP>160/110 mmHg): target sBP <160 mmHg and dBP <110 mmHg, give one of
  - labetalol 20 mg IV then 20-80 mg IV q30 min (max 300 mg), then switch to oral
  - nifedipine immediate release 5-10 mg capsule q30 min
  - hydralazine 5 mg IV, repeat 5-10 mg IV q30 min or 0.5-10 mg/h IV, to a maximum of 20 mg IV (or 30 mg IM)
- no ACEI, ARBs, diuretics (in cases of pulmonary edema or cardiac failure, may be used), prazosin, or atenolol
- pre-existing HTN and gestational HTN without any deterioration can be followed until 37 wk GA, then decide to induce shortly thereafter

Management of Preeclampsia

- if stable and no adverse factors (24-33+6 wk GA): expectant management ± delivery as approaching 34-36 wk (must weigh risks of fetal prematurity vs. risks of developing severe preeclampsia/eclampsia)
  - antenatal corticosteroids should be considered if ≤ 35 wk GA
- if >37 wk GA, delivery is recommended
- for severe preeclampsia, stabilize and deliver, regardless of GA
- if severe preeclampsia during labour, increase maternal monitoring: hourly input and output, hourly neurological vitals, and continuous FHR monitoring
- antihypertensive therapy (as above for severe HTN)
- seizure prevention
  - magnesium sulfate: 4 g IV loading dose, followed by 1g/h
  - postpartum management
  - risk of seizure highest in first 24 h postpartum – continue $MgSO_4$ for 12-24 h after delivery
  - vitals q1 h
  - consider HELLP syndrome
  - most return to a normotensive BP within 2 wk

Management of Eclampsia

- ABCs
- roll patient into LLDP to prevent aspiration
- supplemental O_2 via face mask to treat hypoxemia due to hypoventilation during convulsive episode
- aggressive antihypertensive therapy for sustained dBP ≥109 mmHg or sBP ≥160 mmHg with hydralazine or labetalol
- prevention of recurrent convulsions: to prevent the possible complications of repeated seizure activity (e.g. rhabdomyolysis, metabolic acidosis, aspiration pneumonitis, etc.)
- $MgSO_4$ is the first-line therapy for eclampsia (use for treatment and prophylaxis)
- the definitive treatment of eclampsia is DELIVERY after maternal stabilization, irrespective of gestational age, to reduce the risk of maternal morbidity and mortality from complications of the disease
- mode of delivery is dependent on clinical situation and fetal-maternal condition

Differential Diagnosis of Cause for Seizure in a Pregnant Woman

- Stroke
- Hypertensive disease (hypertensive encephalopathy, pheochromocytoma)
- Space-occupying lesion of the CNS
- Metabolic disorders (hypoglycemia, SIADH)
- Infection (meningitis, encephalitis)
- TTP or thrombophilia
- Idiopathic epilepsy
- Use of illicit drugs
- Cerebral vasculitis

Medical Complications of Pregnancy

Iron and Folate Deficiency Anemia

Table 13. Iron Deficiency and Folate Deficiency Anemia

	Iron Deficiency Anemia	Folate Deficiency Anemia
Etiology	See Hematology, H15	See Hematology, H26
Epidemiology	Responsible for 80% of non-physiologic anemia during pregnancy	Incidence varies from 0.5-25% depending on region, population, and diet
Clinical Features	See Hematology, H15	See Hematology, H26
Investigations	See Hematology, H15	See Hematology, H26
Management	Prevention (non-anemic): 30 mg elemental iron daily (met by most prenatal vitamins) Treatment (anemic): 30-120 mg elemental iron daily 325 mg ferrous fumarate = 106 mg elemental Fe; 325 mg ferrous sulfate = 65 mg elemental Fe; 325 mg ferrous gluconate = 36 mg elemental Fe Polysaccharide-Iron Complex = 150 mg elemental Fe/capsule	Prevention: 0.4-1 mg folic acid PO daily for 1-3 mo preconceptually and throughout T1
Complications	Maternal: angina, CHF, infection, slower recuperation, and PTL Fetal: decreased oxygen carrying capacity leading to fetal distress, IUGR, low birth weight, and fetal neurodevelopment	Maternal: decreased blood volume, N/V, and anorexia Fetal: neural tube defects in T1, low birth weight, and prematurity
Notes	Mother needs 1 g of elemental iron per fetus; this amount exceeds normal stores + dietary intake Iron requirements increase during pregnancy due to fetal/placental growth (500 mg), increased maternal RBC mass (500 mg), and losses (200 mg) – more needed for multiple gestations	Minimum daily requirement is 0.4 mg Most often associated with iron deficiency anemia Folic acid is necessary for closure of neural tube during early fetal development (by day 28 of gestation)

Diabetes Mellitus

Epidemiology
- 2-6% of pregnancies are complicated by DM

Classification of Diabetes Mellitus
- T1DM and T2DM (see Endocrinology, E9)
- GDM: onset of DM during pregnancy (usually tested for around 24-28 wk GA)

Etiology
- T1DM and T2DM
- GDM: anti-insulin factors produced by placenta and high maternal cortisol levels create increased peripheral insulin resistance ➔ leading to GDM and/or exacerbating pre-existing DM

Management

A. T1DM and T2DM

Preconception
- pre-plan and refer to high-risk clinic for interprofessional care
- commence folic acid (1.0 mg daily) 3 mo prior
- optimize glycemic control (HbA1c <7%), counsel and assess for risks and complications (retinopathy, neuropathy, CKD, CVD), review medications (discontinue ACEi, ARBs, statins)

Pregnancy
- for T2DM, switch to insulin therapy and discontinue non-insulin antihyperglycemic agents
  - continuing glyburide or metformin controversial
  - teratogenicity unknown for other oral antihyperglycemics
- tight glycemic control
  - insulin dosage may need to be adjusted as pregnancy advances due to increased demand and increased insulin resistance

Monitoring Glucose Levels
- Frequent measurements of blood glucose during pregnancy are advised for women with T1DM or T2DM to help prevent or treat both hypoglycemia and hyperglycemia, and also improves neonatal outcome
- Aim for:
  - FPG ≤5.3 mmol/L (95 mg/dL)
  - 1 h post prandial PG ≤7.8 mmol/L (140 mg/dL)
  - 2 h post prandial PG ≤6.7 mmol/L (120 mg/dL)
  - Most women can be followed with monthly HbA1c determinations

Post-prandial blood glucose values seem to be the most effective at determining the likelihood of macrosomia or other adverse pregnancy outcomes

- monitor as for normal pregnancy, plus initial 24 h urine protein and creatinine clearance, retinal exam, and HbA1c (aim for <6.5% during pregnancy)
- increased fetal surveillance (fetal growth, BPP, NST) starting in late T2 and T3, consider fetal echocardiogram in T2 (if high HbA1c in T1 or just prior to pregnancy) to look for cardiac abnormalities

Labour
- timing of delivery depends on fetal and maternal health and risk factors (i.e. must consider size of baby, lung maturity, maternal blood glucose)
- induce by 38-39 wk GA for uncomplicated pre-existing diabetes, induce earlier if indicated (poor glycemic control, end-organ involvement)
- increased risk of cephalopelvic disproportion (CPD) and shoulder dystocia with babies >4000 g, consider elective CD for predicted birth weight >4500 g (controversial)
- monitoring
  - during labour, monitor blood glucose q1 h with patient on insulin and dextrose drip
  - aim for blood glucose between 4.0-7.0 mmol/L to reduce the risk of neonatal hypoglycemia

Postpartum
- insulin requirements dramatically drop with expulsion of placenta (source of insulin antagonists)
- monitor glucose q6 h, restart insulin at two-thirds of pre-pregnancy dosage when glucose >8 mmol/L

B. GESTATIONAL DM

Screening and Diagnosis
- all pregnant women between 24-28 wk GA
- 2 screening options
  - 2-step screening (recommended by the Canadian Diabetes Association)
    - step 1: perform a random non-fasting 50 g OGCT
      - 1 h PG <7.8 mmol/L is normal
      - 1 h PG ≥11.1 mmol/L is GDM
      - if 1 h PG 7.8-11.0 mmol/L, proceed to Step 2
    - step 2: perform a fasting 75 g OGTT, GDM if ≥1 of:
      - FPG ≥5.3 mmol/L
      - 1 h PG ≥10.6 mmol/L
      - 2 h PG ≥9.0 mmol/L
  - alternative 1-step screening with fasting 75 g OGTT; GDM if ≥1 of:
    - FPG ≥5.1 mmol/L
    - 1 h PG ≥10.0 mmol/L
    - 2 h PG ≥8.5 mmol/L

Management
- first line: diet modification and increased physical activity
- initiate insulin therapy if glycemic targets not achieved within 2 wk of lifestyle modification alone
  - glycemic targets: FPG <5.3 mmol/L, 1 h PG <7.8 mmol/L, 2 h PG <6.7 mmol/L
- oral agents can be used in pregnancy but is off-label and should be discussed with patient
- stop insulin and diabetic diet postpartum
- follow-up with 75 g OGTT between 6 wk-6 mo postpartum, counsel about lifestyle modifications
- serial BPP/growth starting at 28 wk q3-4 wk
- starting at 36 wk, weekly assessment of fetal wellbeing with either BPP or NST until delivery
- offer IOL between 38-40 wk GA

Prognosis
- most maternal and fetal complications are related to hyperglycemia and its effects
- long-term maternal complications
  - T1DM and T2DM: risk of progressive retinopathy and nephropathy
  - GDM: 50% risk of developing T2DM in next 20 yr

Risk Factors for GDM
- Age >35 yr
- Obesity (BMI ≥30 kg/m²)
- Increased risk in Indigenous, Hispanic, Asian, and African populations
- FHx of DM
- Previous history of GDM
- Previous child with birthweight >4.0 kg
- Polycystic ovarian syndrome
- Current use of glucocorticoids
- Essential HTN or pregnancy-related HTN

Table 14. Complications of DM in Pregnancy

Maternal	Fetal
Obstetric HTN/preeclampsia (especially if pre-existing nephropathy/proteinuria): insulin resistance is implicated in etiology of HTN Polyhydramnios: maternal hyperglycemia leads to fetal hyperglycemia, which leads to fetal polyuria (a major source of amniotic fluid)	**Growth Abnormalities** Macrosomia: maternal hyperglycemia leads to fetal hyperinsulinism resulting in accelerated anabolism IUGR: due to placental vascular insufficiency
Diabetic Emergencies Hypoglycemia Ketoacidosis Diabetic coma	**Delayed Organ Maturity** Fetal lung immaturity: hyperglycemia interferes with surfactant synthesis (respiratory distress syndrome)
End-Organ Involvement or Deterioration (occur in T1DM and T2DM, not in GDM) Retinopathy Nephropathy	**Congenital Anomalies (occur in T1DM and T2DM, not in GDM)** 2-7x increased risk of cardiac (ventricular septal defect), NTD, GU (cystic kidneys), GI (anal atresia), and MSK (sacral agenesis) anomalies due to hyperglycemia Note: Pregnancies complicated by GDM do not manifest an increased risk of congenital anomalies because GDM develops after the critical period of organogenesis (in T1)
Other Pyelonephritis/UTI: glucosuria provides a culture medium for *E. coli* and other bacteria Increased incidence of spontaneous abortion (in T1DM and T2DM, not in GDM): related to pre-conception glycemic control	**Labour and Delivery** PTL/prematurity: most commonly in patients with HTN/preeclampsia PTL is associated with poor glycemic control but the exact mechanism is unknown Increased incidence of stillbirth Birth trauma: due to macrosomia, can lead to difficult vaginal delivery and shoulder dystocia **Neonatal** Hypoglycemia: due to pancreatic hyperplasia and excess insulin secretion in the neonate Hyperbilirubinemia and jaundice: due to prematurity and polycythemia Hypocalcemia: exact pathophysiology not understood, may be related to functional hypoparathyroidism Polycythemia: hyperglycemia stimulates fetal erythropoietin production

Early-Onset Group B *Streptococcus*

Epidemiology
- 15-40% recto-vaginal carrier rate

Risk Factors (for Neonatal Disease)
- <37 completed weeks of gestation at birth
- prolonged rupture of membranes ≥18 h
- maternal intrapartum GBS colonization during current pregnancy
- GBS bacteriuria at any time during the current pregnancy
- previous infant with invasive GBS disease
- maternal fever (temperature ≥38°C)

Clinical Features
- not harmful to mother
- risk of vertical transmission (neonatal sepsis, meningitis or pneumonia, and death)

Investigations
- offer screening to all women at 35-37 wk GA with vaginal and anorectal swabs for GBS culture

Treatment
- prophylactic treatment of maternal GBS at delivery decreases neonatal morbidity and mortality
- antibiotics for GBS prophylaxis (should be given 4 h prior to delivery to be considered adequate)
  - penicillin G 5 million IU IV, then 2.5 million IU IV q4 h until delivery
  - penicillin allergy but low risk for anaphylaxis: cefazolin 2 g IV, then 1 g q8 h
  - penicillin allergy and at risk of anaphylaxis: vancomycin 1 g IV q12 h or clindamycin 900 mg q8 h (only if isolate known to be susceptible to clindamycin) until delivery
  - vancomycin and clindamycin levels in amniotic fluid do not reach therapeutic levels, all babies should be screened for GBS despite treatment
- if maternal fever, broad spectrum antibiotic coverage regardless of GBS status and GA is advised
- if <37 wk GA and in labour or with ROM, IV GBS antibiotic prophylaxis for a minimum of 48 h

Indications for Intrapartum Antibiotic GBS Prophylaxis
Prevention of Perinatal Group B Streptococcal Disease: Revised Guidelines from CDC, 2010. MMWR 2010;59(RR-10):14
- Previous infant with invasive GBS disease
- GBS bacteriuria during any trimester of the current pregnancy
- Positive GBS vaginal-rectal screening culture in late gestation during current pregnancy
- Unknown GBS status at the onset of labour (culture not done, incomplete, or results unknown) and any of the following:
  - Delivery at <37 wk gestation
  - Amniotic membrane rupture ≥18 h
  - Intrapartum temperature ≥38.0°C (≥100.4°F)
  - Intrapartum nucleic-acid amplification test positive for GBS

Urinary Tract Infection

Epidemiology
- most common medical complication of pregnancy
- asymptomatic bacteriuria in 2-7% of pregnant women, more frequently in multiparous women
- note: asymptomatic bacteriuria should be treated in pregnancy due to increased risk of pyelonephritis and PTL

Treat asymptomatic bacteriuria in pregnancy because of increased risk of progression to cystitis, pyelonephritis, and probable increased risk of PTL

Etiology
- increased urinary stasis from mechanical and hormonal (progesterone) factors
- organisms include GBS as well as those that occur in non-pregnant women

Clinical Features
- may be asymptomatic
- dysuria, urgency, and frequency in cystitis
- fever, flank pain, and costovertebral angle tenderness in pyelonephritis

Investigations
- urinalysis, urine C&S
- renal function tests in recurrent infections

Management
- uncomplicated UTI
  - first line: amoxicillin (250-500 mg PO q8 h x 7 d)
  - alternatives: nitrofurantoin (100 mg PO BID x 7 d) or cephalosporins
  - follow with monthly urine cultures
- pyelonephritis
  - hospitalization and IV antibiotics

Prognosis
- complications if untreated: acute cystitis, pyelonephritis, and possible PTL
- recurrence is common

Infections During Pregnancy

Table 15. Infections During Pregnancy

Infection	Agent	Source of Transmission	Greatest Transmission Risk to Fetus	Effects on Fetus	Effects on Mother	Diagnosis	Management
Chicken Pox	Varicella zoster virus (herpes family)	To mother: direct, respiratory To baby: transplacental	13-30 wk GA and 5 d pre- to 2 d post-delivery	Congenital varicella syndrome (limb aplasia, chorioretinitis, cataracts, cutaneous scars, cortical atrophy, IUGR, hydrops), PTL	Fever, malaise, vesicular pruritic lesions	Clinical, ± vesicle fluid culture, ± serology	Varicella-zoster immune globulin for mother if exposed, decreases congenital varicella syndrome Note: do not administer vaccine during pregnancy (live attenuated vaccine)
***Cytomegalovirus**	DNA virus (herpes family)	To mother: blood/organ transfusion, sexual contact To baby: transplacental, during delivery, breast milk	T1-T3	5-10% develop CNS involvement (mental retardation, cerebral calcification, hydrocephalus, microcephaly, deafness, chorioretinitis)	Asymptomatic or flu-like	Serologic screen; isolate virus from urine or secretion culture	No specific treatment; maintain good hygiene and avoid high-risk situations
Erythema Infectiosum (Fifth Disease)	Parvovirus B19	To mother: respiratory, infected blood products To baby: transplacental	10-20 wk GA	Spontaneous abortion (SA), stillbirth, hydrops *in utero*	Flu-like, rash, arthritis; often asymptomatic	Serology, viral PCR, maternal AFP; if IgM present, follow fetus with U/S for hydrops	If hydrops occurs, consider fetal transfusion
Hepatitis B	DNA virus	To mother: blood, saliva, semen, vaginal secretions To baby: transplacental, breast milk	T3 10% vertical transmission if asymptomatic and HBsAg +ve; 85-90% if HBsAg and HBeAg +ve	Prematurity, low birth weight, neonatal death	Fever, N/V, fatigue, jaundice, elevated liver enzymes	Serologic screening for all pregnancies	Rx neonate with HBIG and vaccine (at birth, 1, 6 mo); 90% effective

* Indicates TORCH infection

Table 15. Infections During Pregnancy

Infection	Agent	Source of Transmission	Greatest Transmission Risk to Fetus	Effects on Fetus	Effects on Mother	Diagnosis	Management
***Herpes Simplex Virus**	DNA virus	To mother: intimate mucocutaneous contact To baby: transplacental, during delivery	Delivery (if genital lesions present); less commonly *in utero*	Disseminated herpes (20%); CNS sequelae (35%); self-limited infection	Painful vesicular lesions	Clinical diagnosis	Acyclovir for symptomatic women, suppressive therapy at 36 wk controversial Suggested CD if active genital lesions, even if remote from vulva
HIV	RNA retrovirus	To mother: blood, semen, vaginal secretions To baby: in utero, during delivery, breast milk	1/3 *in utero*, 1/3 at delivery, 1/3 breastfeeding	IUGR, PTL, PROM	See Infectious Diseases, ID26	Serology, viral PCR All pregnant women are offered screening	Triple antiretroviral therapy decreases transmission to <1% Elective CD: no previous antiviral Rx or monotherapy only, viral load unknown or >500 RNA copies/mL, unknown prenatal care, patient request
***Rubella**	ssRNA togavirus	To mother: respiratory droplets (highly contagious) To baby: transplacental	T1	SA or congenital rubella syndrome (hearing loss, cataracts, CV lesions, mitral regurgitation, IUGR, hepatitis, CNS defects, osseous changes)	Rash (50%), fever, posterior auricular or occipital lymphadenopathy, arthralgia	Serologic testing; all pregnant women screened (immune if titre >1:16); infection if IgM present or >4x increase in IgG	No specific treatment; offer vaccine following pregnancy Do not administer during pregnancy (live attenuated)
Syphilis	Spirochete (*Treponema pallidum*)	To mother: sexual contact To baby: transplacental	T1-T3	Risk of PTL, multisystem involvement, fetal death	See Infectious Diseases, ID24	VDRL screening for all pregnancies; if positive, requires confirmatory testing	Benzathine penicillin G 2.4 million IU IM x 1 dose if early syphilis, 3 doses if late syphilis, monitor VDRL monthly No approved alternatives in pregnancy; if beta-lactam allergy, recommend to desensitize then treat with penicillin
***Toxoplasmosis**	Protozoa (*Toxoplasma gondii*)	To mother: raw meat, unpasteurized goat's milk, cat feces/urine To baby: transplacental	T3 (but most severe if infected in T1); only concern if primary infection during pregnancy	Congenital toxoplasmosis (chorioretinitis, hydrocephaly, intracranial calcification, mitral regurgitation, microcephaly) NB: 75% initially asymptomatic at birth	Majority subclinical; may have flu-like symptoms	IgM and IgG serology; PCR of amniotic fluid	Self-limiting in mother; spiramycin decreases fetal morbidity but not rate of transmission

* Indicates TORCH infection

Venous Thromboembolism

Epidemiology

- incidence of 12.1 in 10000 (DVT), and 5.4 in 10000 (PE)
- increased risk of VTE throughout pregnancy with highest risk of DVT in T3 and postpartum period; highest risk of PE postpartum (first 6 wk)

Virchow's Triad for VTE
- Hypercoagulable state
- Stasis
- Endothelial damage

Risk Factors

- previous VTE, age >35, obesity, infection, bedrest/immobility, shock/dehydration, and thrombophilias (see Hematology, H36)

Table 16. Risk Factors for VTE Specific to Pregnancy

Hypercoagulability	Stasis	Endothelial Damage
Increased Factors: II, V, VII, VIII, IX, X, XII, fibrinogen Increased platelet aggregation Decreased protein S, tPA, factors XI, XIII Increased resistance to activated protein C Antithrombin can be normal or reduced	Increased venous distensibility Decreased venous tone 50% decrease in venous flow in lower extremity by T3 Uterus is mechanical impediment to venous return	Vascular damage at delivery (CD or SVD) Uterine instrumentation Peripartum pelvic surgery

Clinical Features

- most DVTs occur in the iliofemoral or calf veins with a predilection for the left leg
- signs of a pulmonary embolism are non-specific

Investigations
- duplex venous Doppler sonography for DVT
- V/Q scan (preferred) or CT angiography for PE

Management
- before initiating treatment, obtain a baseline CBC including platelets and aPTT
- treatment with LMWH preferred
  - dosing varies depending on specific LMWH used
  - should be discontinued at least 24 h prior to delivery
- unfractionated heparin
  - 80 IU/kg bolus (max 5000 IU) followed by 18 IU/kg/h infusion
  - measure aPTT 6 h after the bolus
  - maintain aPTT at a therapeutic level (1.5-2x normal)
  - repeat q24 h once therapeutic
  - heparin-induced thrombocytopenia (HIT) uncommon (3%), but serious complication
- warfarin is contraindicated during pregnancy due to its potential teratogenic effects
- poor evidence to support a recommendation for or against avoidance of prolonged sitting
- VTE prophylaxis
  - women on long-term anticoagulation: full therapeutic anticoagulation throughout pregnancy and for 6-12 wk postpartum
  - women with a non-active PMHx of VTE: unfractionated heparin regimens suggested
  - postpartum thromboprophylaxis should be considered if absolute risk is over 1.0%, defined as:
    - any two of the following: BMI ≥30 at first antepartum visit, smoking >10 cigarettes/d, preeclampsia, IUGR, placenta previa, emergency CD, peripartum/postpartum blood loss >1 L, any low-risk thrombophilia, maternal cardiac disease/SLE/SCD/IBD/varicose veins/GDM, preterm delivery, stillborn
    - any three or more of the following: age >35, parity ≥2, use of ART, multiple pregnancy, placental abruption, PROM, elective CD, maternal cancer
  - current prophylaxis regimens for acquired thrombophilias (e.g. APS) include low dose ASA in conjunction with prophylactic heparin

Normal Labour and Delivery

Definition of Labour
- true labour: regular, painful contractions of increasing intensity associated with progressive dilatation and effacement of cervix and descent of presenting part, or progression of station
  - preterm (≥20 to ≤36+6 wk GA)
  - term (37-41+6 wk GA)
  - postterm (≥42 wk GA)
- false labour (Braxton-Hicks contractions): irregular contractions, with unchanged intensity and long intervals, occur throughout pregnancy and not associated with any cervical dilatation, effacement, or descent
  - often relieved by rest or hydration

The Cervix

- see Bishop Score (see Table 20, OB38)
  - dilatation: latent phase (0-4 cm, variable time); active phase (4-10 cm)
  - effacement: thinning of the cervix by percentage or length of cervix (cm)
  - consistency: firm, medium, or soft
  - position: posterior, mid, or anterior
- other consideration
  - application: contact between the cervix and presenting part (i.e. well or poorly applied)

The Fetus

- **fetal lie**: orientation of the long axis of the fetus with respect to the long axis of the uterus (longitudinal, transverse, and oblique)
- **fetal presentation**: fetal body part closest to the birth canal
  - breech (complete, frank, and incomplete) (see Figure 5, OB25)
  - cephalic (vertex/occiput, face, or brow)
  - transverse (shoulder)
  - compound (fetal extremity prolapses along with presenting part)
  - all except vertex are considered malpresentations (see *Obstetrical Complications*, OB17)
- **fetal position**: position of presenting part of the fetus relative to the maternal pelvis
  - OA: most common presentation ("normal") – left OA most common
  - OP: most rotate spontaneously to OA; may cause prolonged second stage of labour

Maternal Triage Assessment
ID: Age, GPA, EDD, GA, GBS, Rh, Serology
Chief Complaint (CC)
HPI: 4 key questions:
- Contractions: Since when, how close (q x min), how long (x s), how painful
- Bleeding: Since when, how much (pads), colour (pinky vs. brownish vs. bright red), pain, last U/S, trauma/intercourse
- Fluid (ROM): Since when, large gush vs. trickle, soaked pants, clear vs. green vs. red, continuous
- FM: As much as usual, time since last movement, kick counts (lie still for 1-2 h, cold juice, feel FM – should have 6 movements in 2 h)

PregHx: Any complications (HTN, GDM, infections), IPS/FTS, last U/S (BPP score, growth, EFW, presentation), last vaginal exam
POBHx: Every previous pregnancy and outcome: year, SVD/CD/miscarriage/abortion, baby size, length of labour, use of vacuum or forceps, complications
PMHx, Meds, Allergies, SHx
O/E: Maternal vitals, fetal heart tracing (baseline, variability, presence of accelerations/decelerations), Leopold's, vaginal exam, U/S

  - OT: leads to arrest of dilatation
    - normally, fetal head enters maternal pelvis and engages in OT position
    - subsequently rotates to OA position (or OP in a small percentage of cases)
- **attitude**: flexion/extension of fetal head relative to shoulders
  - brow presentation: head partially extended (requires CD)
  - face presentation: head fully extended
    - mentum posterior always requires CD, mentum anterior can deliver vaginally
- **station**: position of presenting bony part relative to ischial spines – determined by vaginal exam
  - at ischial spines = station 0 = engaged
  - –5 to –1 cm above ischial spines
  - +1 to +5 cm below ischial spines
- **asynclitism**: alignment of the sagittal suture relative to the axis of the birth canal
  - lateral tilt seen with either anterior or posterior asynclitism and may impact descent

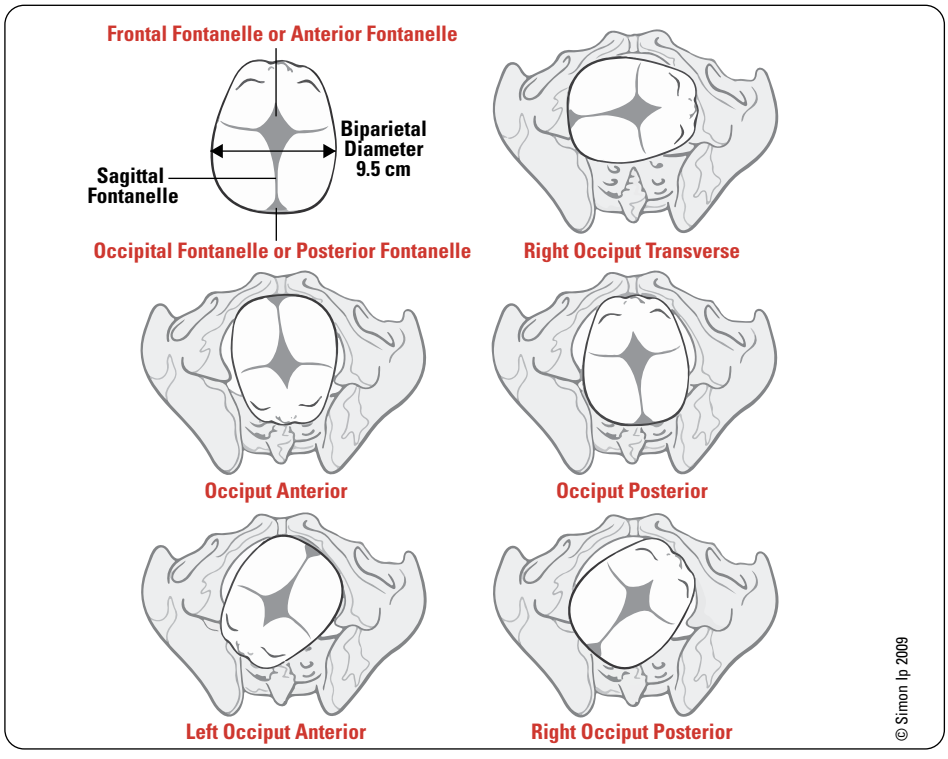

Figure 6. Fetal positions

Reference Point for Describing Fetal Position
- Occiput for cephalic presentation
- Sacrum for breech presentation
- Mentum for face presentation

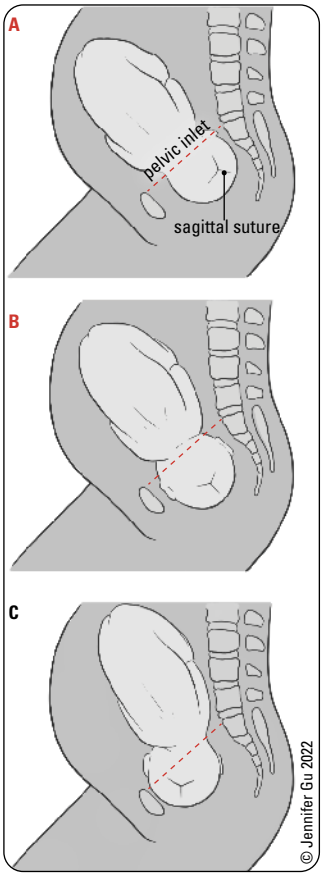

Figure 7. Synclitism and asynclitism

Four Stages of Labour

First Stage of Labour (0-10 cm cervical dilation)
- latent phase
  - uterine contractions typically infrequent and irregular
  - slow cervical dilatation (usually to 4 cm) and effacement
- active phase
  - rapid cervical dilatation to full dilatation (nulliparous ≥1.0 cm/h, multiparous ≥1.2 cm/h)
  - phase of maximum slope on cervical dilatation curve
  - painful, regular contractions q2-3 min, lasting 45-60 s
  - contractions strongest at fundus

Second Stage of Labour (10 cm dilation – delivery of the baby)
- from full dilatation to delivery of the baby; duration varies based on parity, contraction quality, and type of analgesia
- mother feels a desire to bear down and push with each contraction
- women may choose a comfortable position that enhances pushing efforts and delivery
  - upright (semi-sitting, squatting) and LLDP are supported in the literature
- progress measured by descent

Course of Normal Labour*

Stage	Nulliparous	Multiparous
First	6-18 h	2-10 h
Second	30 min-3 h	5-30 min
Third	5-30 min	5-30 min

*without epidural

Signs of Placental Separation
- Gush of blood
- Lengthening of cord
- Uterus becomes globular
- Fundus rises

Third Stage of Labour (delivery of the baby – delivery of the placenta)

- from baby's birth to separation and expulsion of the placenta
- can last up to 30 min before intervention is indicated
- demonstrated by gush of fresh blood, umbilical cord lengthening, uterine fundus changing shape (firm and globular), and rising upward
- active management: start oxytocin IV drip, or give 10 IU IM or 5 mg IV push, after delivery of anterior shoulder in anticipation of placental delivery, otherwise give after delivery of placenta
- routine oxytocin administration in third stage of labour can reduce the risk of PPH by >40%

Fourth Stage of Labour

- first postpartum hour
- monitor vital signs and bleeding, repair lacerations
- ensure uterus is contracted (palpate uterus and monitor uterine bleeding)
- inspect placenta for completeness and umbilical cord for presence of 2 arteries and 1 vein
- 3rd and 4th stages of labour most dangerous to the mother (i.e. hemorrhage)

Continuous Support for Women During Childbirth
Cochrane DB Syst Rev 2017;7:CD003766
Study: Systematic review of 27 trials from 17 countries involving a total of 15858 women
Intervention: Continuous support vs. usual care during labour
Outcome: Effects on mothers and their babies
Results: Women receiving continuous support were slightly more likely to have a spontaneous vaginal birth (RR 1.08, 95% CI 1.04 to 1.12) and shorter labour (mean difference -0.69 h, 95% CI -1.04 to -0.34) and were less likely to use intrapartum analgesia (RR 0.90, 95% CI 0.84 to 0.96), report dissatisfaction with their childbirth experience (RR 0.69, 95% CI 0.59 to 0.79), and have a baby with a low 5 min APGAR score (RR 0.62, 95% CI 0.46 to 0.85)

The Cardinal Movements of the Fetus During Delivery

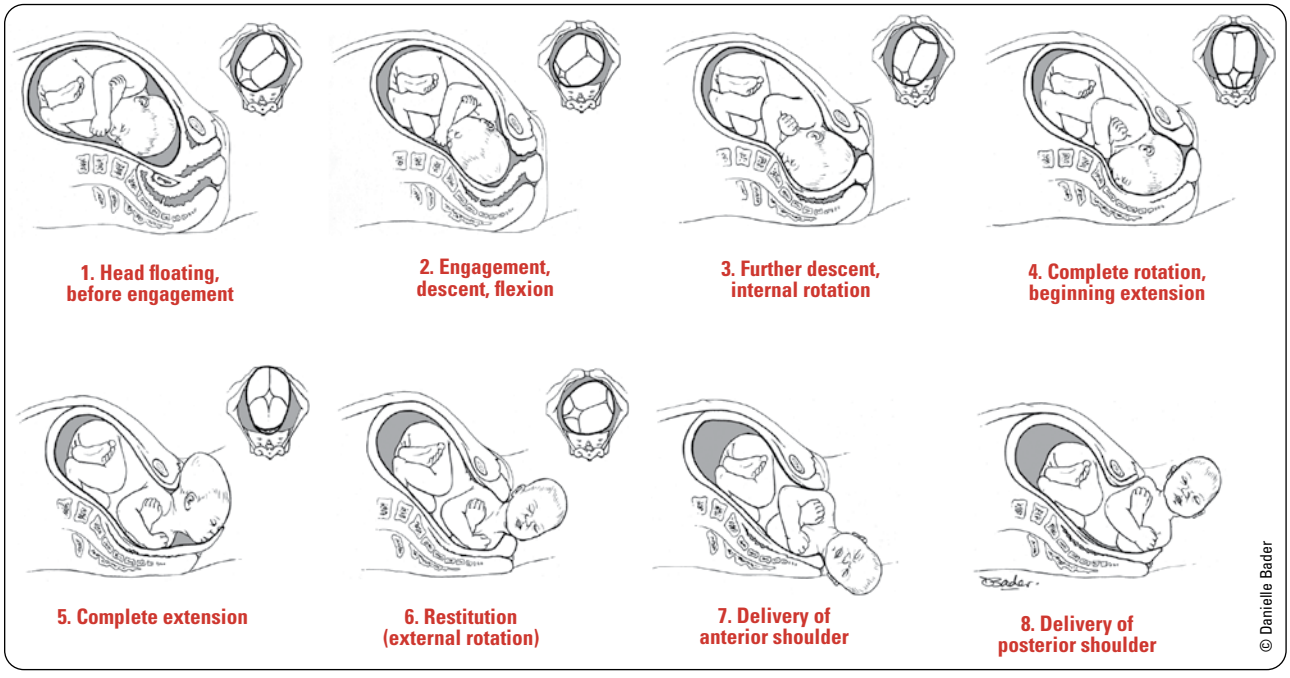

Figure 8. Cardinal movements of fetus during delivery
Adapted from illustration in Williams Obstetrics, 19th ed

Analgesic and Anesthetic Techniques in Labour and Birth

- pain or anxiety leads to high endogenous catecholamines, which produce a direct inhibitory effect on uterine contractility

Non-Pharmacologic Pain Relief Techniques

- reduction of painful stimuli
  - maternal movement, position change, counter-pressure, and abdominal compression
- activation of peripheral sensory receptors
  - superficial heat and cold
  - immersion in water during labour
  - touch and massage, acupuncture, and acupressure
  - TENS
  - intradermal injection of sterile water
  - aromatherapy
- enhancement of descending inhibitory pathways
  - attention focusing and distraction
  - hypnosis
  - music and audio analgesia
  - biofeedback

Pharmacologic Methods (see Anesthesia, A27)
- nitrous oxide (e.g. self-administered Entonox®)
- narcotics (usually combined with anti-emetic)
- pudendal nerve block
- perineal infiltration with local anesthetic
- regional anesthesia (epidural block, combined spinal-epidural, and spinal)

Fetal Monitoring in Labour

- see online **Fetal Heart Rate Tutorial**

Vaginal Exam
- membrane status, as indicated by amniotic fluid (clear, pink, bloody, and meconium)
- cervical effacement (thinning), dilatation, consistency, position, and application
- fetal presenting part, position, and station
- bony pelvis size and shape
- monitor progress of labour at regular intervals and document in a partogram

Intrapartum Fetal Monitoring
- intermittent fetal auscultation with Doppler device q15-30 min for 1 min in first stage active phase following a contraction, q5 min during second stage when pushing has begun
- continuous electronic FHR monitoring reserved for abnormal auscultation, prolonged labour, labour which is induced or augmented, meconium present, multiple gestation/fetal complication, and concerns about the fetus tolerating labour
  - use of continuous electronic monitoring shown to lead to higher intervention rates and no improvement in outcome for the neonate when used routinely in all patients (i.e. no risk factors)
  - techniques for continuous monitoring include external (Doppler) vs. internal (fetal scalp electrode) monitoring
- fetal scalp sampling should be used in conjunction with electronic FHR monitoring and contraction monitoring (CTG) to resolve the interpretation of abnormal or atypical patterns

Electronic FHR Monitoring
- FHR measured by Doppler; contractions measured by tocometer
- described in terms of baseline FHR, variability (short-term, long-term), and periodicity (accelerations, decelerations)
- see Table 5, OB11
- **Baseline FHR**
  - normal range is 110-160 bpm
  - parameter of fetal well-being vs. distress
- **Variability**
  - physiologic variability is a normal characteristic of FHR
  - variability is measured over a 15 min period and is described as: absent, minimal (<6 bpm), moderate (6-25 bpm), or marked (>25 bpm)
  - normal variability indicates fetal acid-base status is acceptable
  - can only be assessed by electronic contraction monitoring (CTG)
  - variability decreases intermittently even in healthy fetus
- **Periodicity**
  - accelerations: increase of ≥15 bpm for ≥15 s (or ≥10 bpm for ≥10 s if <32 wk GA)
  - decelerations: 3 types, described in terms of shape, onset, depth, duration recovery, occurrence, and impact on baseline FHR and variability

Table 17. Factors Affecting Fetal Heart Rate

	Fetal Tachycardia (FHR >160 bpm)	Fetal Bradycardia (FHR <110 bpm)	Decreased Variability
Maternal Factors	Fever, hyperthyroidism, anemia, dehydration	Hypothermia, hypotension, hypoglycemia, position, umbilical cord occlusion	Infection Dehydration
Fetal Factors	Arrhythmia, anemia, infection, prolonged activity, chronic hypoxemia, congenital anomalies	Rapid descent, dysrhythmia, heart block, hypoxia, vagal stimulation (head compression), hypothermia, acidosis	CNS anomalies Dysrhythmia Inactivity/sleep cycle, preterm fetus
Drugs	Sympathomimetics	β-blockers Anesthetics	Narcotics, sedatives Magnesium sulphate, β-blockers
Uteroplacental	Early hypoxia (abruption, HTN) Chorioamnionitis	Late hypoxia (abruption, HTN) Acute cord prolapse Hypercontractility	Hypoxia

Approach to the Management of Abnormal FHR

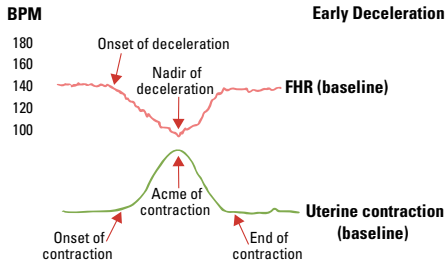
POISON – ER
Position (LLDP)
O$_2$ (100% by mask)
IV fluids (corrects maternal hypotension)
Fetal scalp stimulation
Fetal scalp electrode
Fetal scalp pH
Stop oxytocin
Notify physician
Vaginal exam to rule out cord prolapse
Rule out fever, dehydration, drug effects, and prematurity
• If above fails, consider CD

Continuous Cardiotocography (CTG) as a Form of Electronic Fetal Monitoring (EFM) for Fetal Assessment During Labour
Cochrane DB Syst Rev 2017;5:CD006066
Purpose: To examine the effectiveness of continuous electronic fetal monitoring or cardiotocography during labour
Selection Criteria: Randomized and quasi-randomized controlled trials comparing continuous CTG (with and without fetal blood sampling) to a) no fetal monitoring, b) intermittent auscultation, or c) intermittent CTG
Results: 13 trials, 37000 women. Continuous CTG compared with intermittent auscultation showed no difference in overall perinatal death rate or cerebral palsy rates. Nonetheless, neonatal seizures were halved (RR 0.50, 95% CI 0.31-0.80) and there was a significant increase in CD (RR 1.63, 95% CI 1.29-2.07) and instrumental vaginal birth (RR 1.15, 95% CI 1.01-1.33) with CTG
Conclusion: Continuous CTG may reduce the incidence of neonatal seizures, but has no effect on cerebral palsy rates, infant mortality, or other measures of neonatal well-being. Continuous CTG was also associated with an increase in CD and instrumental deliveries

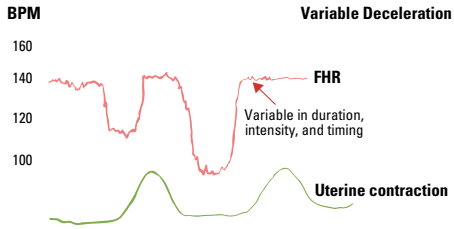
Table 18. Comparison of Decelerations

Comparisons

Early Decelerations
- Uniform shape with onset early in contraction, returns to baseline by end of contraction, mirrors contraction (nadir occurs at peak of contraction)
- Gradual deceleration and return to baseline
- Often repetitive; no effect on baseline FHR or variability
- Benign, due to vagal response to head compression

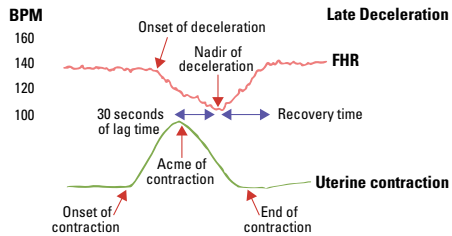


Variable Decelerations
- Variable in shape, onset, and duration
- Most common type of periodicity seen during labour
- Often with abrupt drop in FHR >15 bpm below baseline (>15 s, <2 min); usually no effect on baseline FHR or variability
- Due to cord compression or, in second stage, forceful pushing with contractions



Complicated Variable Decelerations
- FHR drop <60 bpm for >60 s
  - Loss of variability or decrease in baseline after deceleration
  - Biphasic deceleration
  - Slow return to baseline
  - Baseline tachycardia or bradycardia
  - May be associated with fetal acidemia

Late Decelerations
- Uniform shape with onset, nadir, and recovery occurring after peak of contraction, slow return to baseline
- May cause decreased variability and change in baseline FHR
- Due to fetal hypoxia and acidemia, maternal hypotension, or uterine hypertonus
- Usually a sign of uteroplacental insufficiency (an ominous sign)



Rule of 60s Suggesting Severe Variable Decelerations
Deceleration to <60 bpm
>60 bpm below baseline
>60 s in duration with slow return to baseline

Fetal Scalp Blood Sampling
- cervix must be adequately dilated
- indicated when atypical or abnormal FHR is suggested by clinical parameters including heavy meconium or moderately to severely abnormal FHR patterns (including unexplained low variability, repetitive late decelerations, complex variable decelerations, and fetal cardiac arrhythmias)
- done by measuring pH or more recently fetal lactate
  - pH ≥7.25, lactate <4.2 mmol/L: normal, repeat if abnormal FHR persists
  - pH 7.21-7.24, lactate 4.2-4.8 mmol/L: repeat assessment in 30 min or consider delivery if rapid fall since last sample
  - pH ≤7.20, lactate >4.8 mmol/L indicates fetal acidosis, delivery is indicated
- contraindications
  - known or suspected fetal blood dyscrasia (hemophilia, VWD)
  - active maternal infection (HIV, genital herpes)

Fetal Oxygenation
- uterine contractions during labour decrease uteroplacental blood flow, which results in reduced oxygen delivery to the fetus
- most fetuses tolerate this reduction in flow and have no adverse effects
- distribution of oxygen to the fetus depends on maternal, uteroplacental, and fetal factors
- fetal response to hypoxia/asphyxia:
  - decreased movement, tone, and breathing activities
  - anaerobic metabolism (decreased pH)
  - transient fetal bradycardia followed by fetal tachycardia
  - redistribution of fetal blood flow
- increased flow to brain, heart, and adrenals
- decreased flow to kidneys, lungs, gut, liver, and peripheral tissues
- increase in blood pressure

Table 19. Factors Affecting Fetal Oxygenation

Factor	Mechanism	Example
Maternal	Decreased maternal oxygen carrying capacity	Significant anemia (iron deficiency, hemoglobinopathies), carboxyhemoglobin (smokers)
	Decreased uterine blood flow	Hypotension (blood loss, sepsis), regional anesthesia, maternal positioning
	Chronic maternal conditions	Vasculopathies (SLE, T1DM, chronic HTN), APS, cyanotic heart disease, COPD
Uteroplacental	Uterine hypertonus	Placental abruption, tachysystole secondary to oxytocin, prostaglandins, or normal labour
	Uteroplacental dysfunction	Placental abruption, placental infarction (dysfunction marked by IUGR, oligohydramnios, abnormal Doppler studies), chorioamnionitis, placental edema (DM, hydrops), placental senescence (post-dates)
Fetal	Cord compression	Oligohydramnios, cord prolapse, or entanglement
	Decreased fetal oxygen carrying capacity	Significant anemia (isoimmunization, feto-maternal bleed), carboxyhemoglobin (exposure to smokers)

Induction and Augmentation of Labour

Induction of Labour

Definition

- artificial initiation of labour in a pregnant woman prior to spontaneous initiation to deliver the fetus and placenta

Prerequisites for Labour Induction

- capability for CD if necessary
- maternal
  - inducible/ripe cervix: short, thin, soft, anterior cervix with open os
  - if cervix is not ripe, use prostaglandin vaginal insert (Cervidil®), prostaglandin gel (Prepidil®), misoprostol (Cytotec®), or Foley catheter
- fetal
  - normal fetal heart tracing
  - cephalic presentation
  - adequate fetal monitoring available
- likelihood of success determined by Bishop score
  - cervix considered unfavourable if <6
  - cervix favourable if ≥6
  - score of 9-13 associated with high likelihood of vaginal delivery

Table 20. Bishop Score

Cervical Characteristic	0	1	2	3
Position	Posterior	Mid	Anterior	–
Consistency	Firm	Medium	Soft	–
Effacement (%)	0-30	40-50	60-70	≥80
Dilatation (cm)	0	1-2	3-4	≥5
Station of Fetal Head	-3	-2	-1, 0	+1, +2, +3

Indications

- late term and post-dates pregnancy = most common reason for induction
- 39-41 wk GA especially with risk factors such as advanced maternal age (>40 yr): consideration should be given to IOL due to increased risk of stillbirth
- >41 wk GA: offer IOL if vaginal delivery is not contraindicated
  - IOL shown to decrease CD, FHR changes, meconium staining, macrosomia, and death when compared with expectant management
- >41 wk GA and expectant management elected: serial fetal surveillance
  - FM count by the mother
  - BPP q3-4 d
- maternal factors
  - DM = second most common reason for induction
  - gestational HTN ≥38 wk GA
  - preeclampsia ≥37 wk GA
  - other maternal medical problems, e.g. renal or lung disease, chronic HTN, and cholestasis
  - significant but stable antepartum hemorrhage
  - labour induction may be offered to patients age ≥40 at ≥39 wk GA due to increased risk of stillbirth

Induction is indicated when the risk of continuing pregnancy exceeds the risks associated with induced labour and delivery

Induction vs. Augmentation
Induction is the artificial initiation of labour
Augmentation promotes contractions when spontaneous contractions are inadequate

Consider the Following Before Induction
- Indication for induction
- Contraindications
- GA
- Cervical favourability
- Fetal presentation
- Potential for CPD
- Fetal well-being/FHR
- Membrane status

- maternal-fetal factors
  - isoimmunization, PROM, and chorioamnionitis
- fetal factors
  - suspected fetal jeopardy as evidenced by biochemical or biophysical indications
  - macrosomia, fetal demise, IUGR, oligo/polyhydramnios, anomalies requiring surgical intervention, and twins
  - previous stillbirth or low PAPP-A

Risks
- failure to achieve labour and/or vaginal birth
- tachysystole with fetal compromise or uterine rupture
- maternal side effects to medications
- uterine atony and PPH if labour is prolonged

Contraindications
- maternal
  - prior classical or inverted T-incision CD or uterine surgery (e.g. myomectomy)
  - unstable maternal condition
  - active maternal genital herpes
  - invasive cervical carcinoma
  - pelvic structure deformities
  - previous uterine rupture
- maternal-fetal
  - placenta previa or vasa previa
  - cord presentation
- fetal
  - fetal distress or malpresentation/abnormal lie

Methods for Induction of Labour

CERVICAL RIPENING

Definition
- use of medications or other means to soften, efface, and dilate the cervix; increases likelihood of successful induction
- ripening of an unfavourable cervix (Bishop score <6) is warranted prior to induction of labour

Methods
- intravaginal prostaglandin PGE2 gel (Prostin® gel): long and closed cervix
  - recommended dosing interval of prostaglandin gel is every 6-12 h up to 3 doses
- intravaginal PGE2 (Cervidil®): long and closed cervix, may use if ROM
  - continuous release, can be removed if needed
  - controlled release PGE2
- intracervical PGE2 (Prepidil®)
- intravaginal PGE1 misoprostol (Cytotec®): long and closed cervix
  - inexpensive, stored at room temperature
  - more effective than PGE2 for achieving vaginal delivery and less epidural use
- Foley catheter placement to mechanically dilate the cervix

INDUCTION OF LABOUR

Amniotomy
- artificial ROM (amniotomy) to stimulate prostaglandin synthesis and secretion; may try this as initial measure if cervix is open and soft, the membranes can be felt, and if the head is present at the cervix
- few studies address the value of amniotomy alone for induction of labour
- amniotomy plus intravenous oxytocin: more women delivered vaginally at 24 h than amniotomy alone (RR=0.03) and had fewer instrumental vaginal deliveries (RR=5.5)

Oxytocin
- oxytocin (Pitocin®): 10 U in 1 L normal saline, run at 0.5-2 mU/min IV increasing by 1-2 mU/min q20-60 min
- reduces rate of unsuccessful vaginal deliveries within 24 h when used alone (8.3% vs. 54%, RR=0.16)
- ideal dosing regimen of oxytocin is not known
- current recommendations: use the minimum dose to achieve active labour and increase q30 min as needed
- reassessment should occur once a dose of 20 mU/min is reached
- potential complications
  - tachysystole/tetanic contraction (may cause fetal distress or uterine rupture)
  - uterine muscle fatigue, uterine atony (may result in PPH)
  - vasopressin-like action causing anti-diuresis

Evidence for Cervical Ripening Methods (SOGC Guidelines)
- Meta-analysis of five trials has concluded that the use of oxytocin to ripen the cervix is not effective
- Since the best dose and route of misoprostol for labour induction with a live fetus are not known and there are concerns regarding hyperstimulation, the use of misoprostol for induction of labour should be in cases of intrauterine fetal death to initiate labour

Vaginal Prostaglandin (PGE2 and PGF2a) for Induction of Labour at Term
Cochrane DB Syst Rev 2014;6:CD003101
This analysis examined the results of 70 RCTs (n=11487 women). Use of vaginal PGE2 increased the risk of uterine hyperstimulation with FHR changes (RR 3.16; 95% CI 1.67-5.98) and likely reduces the CD rate slightly (RR 0.91; 95% CI 0.81-1.02) compared to placebo or no treatment. There were no detectable differences in effectiveness between gel or tablet forms of PGE2 or between sustained release pessaries and PGE2 gel/tablets
Theoretical advantages between intravaginal PGE2 (Cervidil®) compared to Intravaginal Prostaglandin Gel:
- Slow, continuous release
- Ability to use oxytocin 30 min after removal vs. 6 h for gel
- Ability to remove insert if required (e.g. excessive uterine activity)

Labour Induction vs. Expectant Management in Low-Risk Nulliparous Women
NEJM 2018;379:513-523
Purpose: To assess whether induction of labour between 39+0 wk and 40+6 wk improves perinatal and maternal outcomes
Methods: 6106 low-risk nulliparous women were randomized to the elective induction or the expectant management groups. The primary outcome was a composite outcome of perinatal death or severe neonatal complications. The main secondary outcome was the rate of CD
Results: The primary perinatal outcome occurred in 4.3% of neonates from the elective induction group and 5.4% of neonates from the expectant management group (RR: 0.80; 95% CI: 0.64-1.00; P=0.049, P<0.046 for significance). This result was consistent after adjusting for other maternal factors. CD occurred in 18.6% of induction group mothers compared to 22.3% of expectant management group mothers (RR: 0.84; 95% CI: 0.76-0.93, P<0.001). There were no significant differences in primary or secondary outcomes in subgroup analyses
Conclusion: Elective induction of labour between 39 and 41 wk GA did not result in increased incidence of adverse perinatal outcomes and resulted in fewer CDs

Oxytocin t½ = 3-5 min

Augmentation of Labour

- augmentation of labour with amniotomy and/or oxytocin may be used to promote stronger and more frequent contractions when spontaneous contractions are inadequate and cervical dilatation or descent of fetus fails to occur

Provided there are no contraindications, oxytocin is used to improve uterine contraction strength and/or frequency

Abnormalities and Complications of Labour and Delivery

Abnormal Progression of Labour (Dystocia)

Definition

- expected patterns of descent of the presenting part and cervical dilatation fail to occur in the appropriate time frame; can occur in all stages of labour
- during active phase: >4 h of <0.5 cm/h
- during 2nd stage: >1 h with no descent during active pushing

Etiology

- power (leading cause): contractions (hypotonic, uncoordinated), inadequate maternal expulsive efforts
- passenger: fetal position, attitude, size, anomalies (hydrocephalus)
- passage: pelvic structure (CPD), maternal soft tissue factors (tumours, full bladder or rectum, vaginal septum)
- psyche: hormones released in response to stress may contribute to dystocia; psychological and physiological stress should be evaluated as part of the management once dystocia has been diagnosed

The 4 Ps of Dystocia
Power
Passenger
Passage
Psyche

Management

- confirm diagnosis of labour (rule out false labour)
- search for factors of CPD
- concern for dystocia if adequate contractions measured by intrauterine pressure catheter with no descent/dilatation for >2 h
- management: if CPD ruled out, IV oxytocin augmentation ± amniotomy, optimize fetal position, optimize pain control

Risks of Dystocia

- inadequate progression of labour is associated with an increased incidence of:
  - maternal stress
  - maternal infection
  - PPH
  - need for neonatal resuscitation
  - fetal compromise (from tachysystole)
  - uterine rupture
  - hypotension

Shoulder Dystocia

Definition

- fetal anterior shoulder impacted above pubic symphysis after fetal head has been delivered
- life threatening emergency

Etiology/Epidemiology

- incidence 0.15-1.4% of deliveries
- occurs when breadth of shoulders is greater than biparietal diameter of the head

Risk Factors

- maternal: obesity, DM, multiparity, and previous shoulder dystocia
- fetal: prolonged gestation or macrosomia (especially if associated with GDM)
- labour
  - prolonged 2nd stage
  - instrumental midpelvic delivery

Presentation
- "turtle sign": head delivered but retracts against inferior portion of pubic symphysis
- complications
  - fetal
    - hypoxic ischemic encephalopathy (chest compression by vagina or cord compression by pelvis can lead to hypoxia)
    - brachial plexus injury (Erb's palsy: C5-C7; Klumpke's palsy: C8-T1), 90% resolve within 6 mo
    - fracture (clavicle, humerus, and cervical spine)
    - death
  - maternal
    - perineal injury
    - PPH (uterine atony or lacerations)
    - uterine rupture

Treatment
- goal: to displace anterior shoulder from behind symphysis pubis; follow a stepwise approach of maneuvers until goal achieved (see sidebar)
- other options
  - cleidotomy (deliberate fracture of neonatal clavicle)
  - Zavanelli maneuver: replacement of fetus into uterine cavity and emergent CD
  - symphysiotomy

Approach to the Management of Shoulder Dystocia

ALARMER
Ask for help
Legs in full flexion (McRoberts maneuver)
Anterior shoulder disimpaction (suprapubic pressure)
Release posterior shoulder by rotating it anteriorly with hand in the vagina under adequate anesthesia
Manual corkscrew i.e. rotate the fetus by the posterior shoulder until the anterior shoulder emerges from behind the maternal symphysis
Episiotomy
Rollover (on hands and knees)
*Note that suprapubic pressure and McRoberts maneuver together will resolve 90% of cases

Prognosis
- 1% risk of long-term disability for infant

Umbilical Cord Prolapse

Definition
- descent of the cord to a level adjacent to or below the presenting part, causing cord compression between presenting part and pelvis

Etiology/Epidemiology
- increased incidence with prematurity/PROM, fetal malpresentation (~50% of cases), low-lying placenta, polyhydramnios, multiple gestation, and CPD
- incidence: 1 in 200 to 1 in 400 deliveries

Presentation
- visible or palpable cord
- FHR changes (variable decelerations, bradycardia, or both)

Treatment
- emergency CD if not fully dilated and vaginal delivery not imminent
- O_2 to mother, monitor fetal heart
- alleviate pressure of the presenting part on the cord by elevating fetal head with a pelvic exam (maintain this position until CD)
- keep cord warm and moist by replacing it into the vagina ± applying warm saline soaks
- roll mother onto all fours or position mother in Trendelenburg or knee-to-chest position
- if fetal demise or too premature (<22 wk GA), allow labour and delivery

Umbilical Cord Accident Causes
- Nuchal cord
- Type A (looped)
- Type B (hitched)
- Body loop
- Single artery
- True knot
- Torsion
- Velamentous
- Short cord <35 cm
- Long cord >80 cm

1/3 of protraction disorders develop into 2° arrest of dilatation due to CPD

2/3 of protraction disorders progress through labour to vaginal delivery

Uterine Rupture

Definition
- associated with previous uterine scar (in 40% of cases), tachysystole with oxytocin, grand multiparity, and previous intrauterine manipulation
- generally occurs during labour, but can occur earlier with a classical incision
- 0.5-0.8% incidence, up to 12% with classical incision

Presentation
- prolonged fetal bradycardia (most common presentation)
- acute onset of constant lower abdominal pain, may not have pain if receiving epidural analgesia
- hyper/hypotonic uterine contractions
- abnormal progress in labour
- vaginal bleeding
- intra-abdominal hemorrhage
- loss of station of the presenting fetal part
- maternal tachycardia, hypotension, or shock

Risk Factors
- uterine scarring (e.g. previous uterine surgeries including CD (especially classical incision), perforation with D&C, and myomectomy)
- excessive uterine stimulation (e.g. protracted labour, oxytocin, and prostaglandins)
- uterine trauma (e.g. operative equipment, ECV)
- multiparity
- uterine abnormalities
- malpresentation
- placenta accreta

Treatment
- rule out placental abruption
- maternal stabilization (may require hysterectomy), treat hypovolemia
- immediate delivery for fetal survival

Complications
- maternal mortality 1-10%
- maternal hemorrhage, shock, DIC
- amniotic fluid embolus
- hysterectomy if uncontrollable hemorrhage
- fetal distress, associated with infant mortality as high as 15%

Maternal Mortality Causes
- Thromboembolism
- Cardiac event
- Suicide
- Sepsis
- Ectopic pregnancy
- HTN
- Amniotic fluid embolism
- Hemorrhage

*In Canada (2013), lifetime risk of maternal death is 1/5200

Amniotic Fluid Embolism

Definition
- amniotic fluid debris in maternal circulation triggering an anaphylactoid immunologic response

Etiology/Epidemiology
- rare intrapartum or immediate postpartum complication
- 13-30% maternal mortality rate
- leading cause of maternal death in induced abortions and miscarriages
- 1 in 8000 to 1 in 80000 births

Risk Factors
- placental abruption
- rapid labour
- multiparity
- uterine rupture
- uterine manipulation
- induction medication and procedures

Differential Diagnosis
- pulmonary embolus, drug-induced anaphylaxis, septic shock, eclampsia, HELLP syndrome, abruption, and chronic coagulopathy

Presentation
- sudden onset of respiratory distress, cardiovascular collapse (hypotension, hypoxia), and coagulopathy
- seizure in 10%
- ARDS and left ventricular dysfunction seen in survivors

Management
- should be managed in the ICU by a multidisciplinary team
- supportive measures (high flow O_2, ventilation support, fluid resuscitation, inotropic support, ± intubation) and coagulopathy correction

Chorioamnionitis

Definition
- infection of the chorion, amnion, and amniotic fluid

Etiology/Epidemiology
- incidence 1-5% of term pregnancies and up to 25% in preterm deliveries
- ascending infection (microorganisms from vagina)
- predominant microorganisms include: GBS, *Bacteroides* and *Prevotella* species, *E. coli*, and anaerobic *Streptococcus*

Risk Factors
- low parity, prolonged ROM, long labour, multiple vaginal exams during labour, and internal monitoring
- bacterial vaginosis and other vaginal infections

Clinical Features
- maternal fever ≥38°C, maternal or fetal tachycardia, uterine tenderness, and foul and purulent cervical discharge

Investigations
- CBC: leukocytosis
- amniotic fluid: Gram stain, glucose, or culture results consistent with infection

Treatment
- IV antibiotics
  - ampicillin 2 g IV q6 h + gentamicin 2 mg/kg load, then 1.5 mg/kg IV q8 h
  - anaerobic coverage (i.e. clindamycin 900 mg IV q 8 h)
  - if at risk for endometritis, continue treatment postpartum especially if CD
- antipyretics
- proper labour progression (not an indication for immediate delivery or CD, especially if delivery is imminent and can be done safely)

Complications
- bacteremia of mother or fetus, wound infection if CD, pelvic abscess, neonatal meningitis, neonatal sepsis, and neonatal death
- long-term infant complications: cerebral palsy and bronchopulmonary dysplasia

Clinical Features of Chorioamnionitis
- Temperature
- Tachycardia (maternal or fetal)
- Tenderness (uterine)
- Foul discharge

Meconium

Epidemiology
- present early in labour in 10% of pregnancies, more common in post-date pregnancies
- in general, meconium may be present in up to 25% of all labours; usually NOT associated with poor outcome
- concern if fluid changes from clear to meconium-stained
- always abnormal if seen in preterm fetus

Etiology
- likely cord compression ± uterine hypertonia
- may indicate undiagnosed breech
- increasing meconium during labour may be a sign of fetal distress

Features
- may be watery or thicker (particulate)
- light yellow/green or dark green-black in colour

Treatment
- call respiratory therapy, neonatology, or paediatrics to delivery room
- closely monitor FHR for signs of fetal distress

Particulate (thickened) meconium is associated with lower APGARs, an increased risk of meconium aspiration, and perinatal death. Particulate meconium generally has a darker green or black colour, whereas thin meconium is usually yellow to light green

Operative Obstetrics

Operative Vaginal Delivery

Definition
- forceps or vacuum extraction

Indications
- fetal
  - atypical or abnormal FHR tracing, evidence of fetal compromise
  - consider if second stage is prolonged, as this may be due to poor contractions or failure of fetal head to rotate
- maternal
  - need to avoid voluntary expulsive effort (e.g. cardiac/cerebrovascular disease)
  - exhaustion, lack of cooperation, and excessive analgesia may impair pushing effort

Prerequisites for Operative Vaginal Delivery

ABCDEFGHIJK
Anesthesia (adequate)
Bladder empty
Cervix fully dilated and effaced with ROM
Determine position of fetal head
Equipment ready (including facilities for emergent CD)
Fontanelle (posterior fontanelle midway between thighs)
Gentle traction
Handle elevated
Incision (episiotomy)
Once jaw visible remove forceps
Knowledgeable operator

Contraindications
- unknown fetal head position
- unengaged head
- fetal bone demineralization disorder (e.g. osteogenesis imperfecta)
- fetal bleeding disorder (e.g. hemophilia or VWD)

Forceps

Outlet Forceps
- head visible between labia in between contractions
- sagittal suture in or close to AP diameter
- rotation cannot exceed 45°

Low Forceps
- presenting part at station +2 or greater
- subdivided based on whether rotation less than or greater than 45°

Mid Forceps
- presenting part below spines but above station +2

Types of Forceps
- Simpson or Tucker-McLane forceps for OA presentations
- Kielland (rotational) forceps when rotation of head or correction of asynclitism is required
- Piper forceps for after-coming head in breech delivery
- Wrigley's for preterm babies

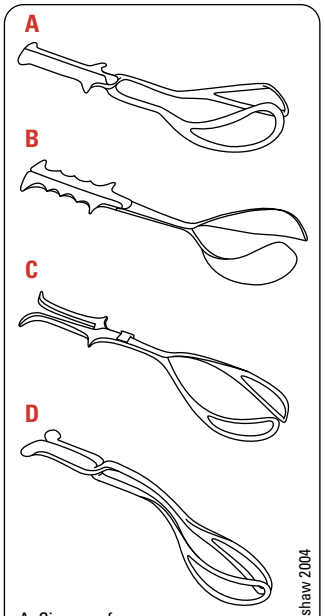


Figure 9. Types of forceps

Vacuum Extraction

- traction instrument used as alternative to forceps delivery; aids maternal pushing
- contraindications: <34 wk GA (<2500 g), fetal head deflexed, fetus requires rotation, fetal condition (e.g. bleeding disorder)

Table 21. Advantages and Disadvantages of Forceps vs. Vacuum Extraction

	Forceps	Vacuum Extraction
Advantages	Higher overall success rate for vaginal delivery Decreased incidence of fetal morbidity	Easier to apply Less anesthesia required Less maternal soft-tissue injury compared to forceps
Disadvantages	Greater incidence of maternal injury	Suitable only for vertex presentations Contraindicated in preterm delivery
Complications	Maternal: anesthesia risk, cervical/vaginal/perineal lacerations including OASIS, injury to bladder, uterus, or bone, pelvic nerve damage, PPH, and infections Fetal: fractures, facial nerve palsy, trauma to face/scalp, intracerebral hemorrhage, cephalohematoma, and cord compression	Increased incidence of cephalohematoma, retinal hemorrhages, and jaundice compared to forceps Subgaleal hemorrhage Subaponeurotic hemorrhage Soft tissue trauma Increased maternal risk of perineal lacerations/OASIS, PPH, and infection

Perineal Lacerations

- 1st degree: involves skin and vaginal mucosa but not underlying fascia and muscle
- 2nd degree: involves fascia and muscles of the perineal body but not the anal sphincter
- 3rd degree: involves the anal sphincter (3A: <50% of external anal sphincter; 3B: >50% of external anal sphincter; 3C: external anal sphincter and internal anal sphincter)
- 4th degree: extends through the anal sphincter complex (external and internal) and into the rectal mucosa
- for 3rd and 4th-degree tears, a single prophylactic dose of IV antibiotics (2nd generation cephalosporin, e.g. cefoxitin or cefotetan) should be administered to reduce perineal wound complications; laxatives should also be prescribed and constipation should be avoided; recommend postpartum pelvic physiotherapy and transanal US to assess integrity of anal sphincter post repair

Limits for Trial of Vacuum
- After 3 pulls over 3 contractions with no progress
- After 3 pop-offs with no obvious cause
- 20 min and delivery is not imminent

Risk Factors for the Development of Obstetric Anal Sphincter Injuries in Modern Obstetric Practice
Obstet Gynecol 2018;131(2):290-296
Purpose: To characterize the rate of obstetric anal sphincter injuries and identify risk factors of obstetric anal sphincter injuries, including duration of the second stage of labour
Methods: Retrospective cohort study including all singleton, term, cephalic vaginal deliveries from 2013 to 2014
Results: The overall incidence rate of obstetric anal sphincter injuries was 4.9% (3.6% of women who delivered spontaneously vs. 24.0% of women who had a vacuum-assisted vaginal delivery, P<0.001, 95% CI 18.1–22.6%). Further analyses suggested that incidence was higher among women with second stage of labour longer than 2 h, Asian race, nulliparity, vaginal birth after caesarean delivery, episiotomy, and vacuum delivery. Women with a vacuum-assisted vaginal delivery had four times the odds of obstetric anal sphincter injury (adjusted odds ratio = 4.23, 95% CI 3.59-4.98) and those whose second stage of labour lasted at least 180 min vs. less than 60 min had three times the odds of injury (adjusted odds ratio = 3.20, 95% CI 2.62-3.89)
Conclusion: Vacuum-assisted vaginal delivery had the highest odds of obstetric anal sphincter injury followed by prolonged second stage of labor. Risk factors should be used to guide decision-making

Episiotomy

Definition
- incision in the perineal body at the time of delivery
- essentially a controlled second-degree laceration
- midline: incision through central tendinous portion of perineal body and insertions of superficial transverse perineal and bulbocavernosus muscles
  - heals better, but increases risk of extension into a 3rd/4th degree tear
- mediolateral: incision through bulbocavernosus, superficial transverse perineal muscle, and levator ani, 60 degree angle from midline
  - reduced risk of extensive tear, but more painful

Indications
- to relieve obstruction of the unyielding perineum
- to expedite delivery (e.g. abnormal FHR pattern)
- instrumental delivery
- controversial between practitioners as to whether it is preferable to make a cut or let the perineum tear as needed
- current evidence suggests letting perineum tear and then repair as needed (restricted use)

Complications
- infection, hematoma, extension into anal musculature or rectal mucosa, fistula formation, and incontinence

Caesarean Delivery

Epidemiology
- overall 28% rate in Canada (range 18.5-35.3% by province/territory)

Indications
- maternal: obstruction of descent (e.g. maternal fibroids), active herpetic lesion on vulva, invasive cervical cancer, previous uterine surgery (past CD is most common), and underlying maternal illness (eclampsia, HELLP syndrome, heart disease)
- maternal-fetal: failure to progress, placental abruption or previa, and vasa previa
- fetal: abnormal fetal heart tracing, malpresentation, cord prolapse, certain congenital anomalies, and multiple pregnancy

Types of Caesarean Incisions
- skin
  - transverse (Pfannenstiel)
    - decreased exposure and slower entry
    - improved strength and cosmesis
  - vertical midline
    - rapid peritoneal entry and increased exposure (e.g. obstruction due to large fibroids)
    - increased dehiscence
- uterine
  - low transverse (most common): in non-contractile lower segment
    - decreased chance for rupture in subsequent pregnancies
  - low vertical
    - used for very preterm infants or poorly developed maternal lower uterine segment
  - classical (rare): in thick, contractile segment
    - used for transverse lie with fetal back down, preterm breech, fetal anomaly, >2 fetuses, lower segment adhesions, obstructing fibroid, and inaccessible lower uterine segment (e.g. morbid obesity)

Risks/Complications
- anesthetic complications (e.g. aspiration)
- hemorrhage (average blood loss ~1000 cc)
- infection (UTI, wound, and endometritis)
  - single dose prophylactic antibiotic should be used (e.g. cefazolin 1-2 g IV)
- injury to surrounding structures (bowel, bladder, ureter, and uterus)
- thromboembolism (DVT, PE)
- increased recovery time/hospital stay
- maternal mortality (<0.1%)
- subsequent placenta accreta

Common OR Questions

7 Layers to Dissect
Skin, fatty layer, fascia, muscle separation (rectus abdominis), peritoneum, bladder flap, uterus

Layers of the Rectus Sheath
Above the arcuate line: anterior rectus sheath (aponeurosis of external oblique, anterior internal oblique), rectus abdominis, posterior rectus sheath (aponeurosis of posterior internal internal oblique, transversus abdominis)
Below the arcuate line: aponeurosis of external oblique, internal oblique, transversus abdominis (all anterior)

Name of the Obliterated Umbilical Ligament
Urachus

Most CDs are performed with regional analgesia

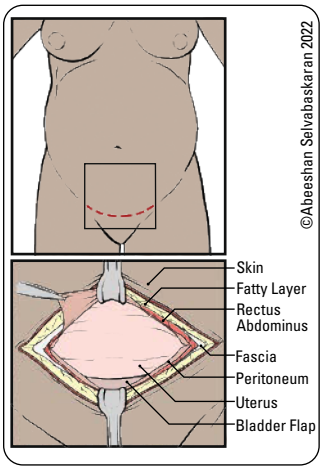

Figure 10. Layers to dissect

Trial of Labour after Caesarean (TOLAC)

- should be recommended if no contraindications after previous low transverse incision
- success rate varies with indication for previous CD (generally 60-80%)
- risk of uterine rupture (<1% with low transverse incision), increased by interval <18 mo and oxytocin administration

Contraindications
- previous classical, inverted T, or unknown uterine incision, or complete transection of uterus (6% risk of rupture)
- any contraindication to vaginal birth, such as non-vertex presentation or placenta previa
- inadequate facilities or personnel for emergency CD

TOLAC*
- Rate of successful TOLAC ranges from 60-82%
- No significant difference in maternal deaths or hysterectomies between TOLAC or CD
- Uterine rupture more common in TOLAC group
- Evidence regarding fetal outcome is lacking

*Safety of vaginal birth after Caesarean section: A systematic review. Obstet Gynecol 2004;103:420-429

Puerperal Complications

- puerperium: 6 wk period of adjustment after pregnancy when pregnancy-induced anatomic and physiologic changes are reversed

Postpartum Hemorrhage

Definition
- loss of >1000 mL of blood after CD, >500 mL of blood after vaginal delivery, or bleeding associated with signs/symptoms of hypovolemia within 24 h of birthing process regardless of mode of delivery
- primary – within first 24 h postpartum
- secondary – after 24 h but within first 12 wk

Uterine atony is the most common cause of PPH

Epidemiology
- incidence 5-15%

Etiology (4 Ts)

DDx of Early PPH – 4 Ts
Tone (atony)
Tissue (retained placenta, clots)
Trauma (laceration, inversion)
Thrombin (coagulopathy)

DDx of Late PPH
Retained products
± endometritis
Sub-involution of uterus

1. Tone (uterine atony)
- most common cause of PPH (70-80%)
- avoid with active management of 3rd stage of labour with 1) oxytocin administration 2) uterine massage 3) umbilical cord traction for delivery of the placenta
- due to:
  - overdistended uterus (polyhydramnios, multiple gestations, and macrosomia)
  - uterine muscle exhaustion (prolonged or rapid labour, grand multiparity, oxytocin use, and general anesthetic)
  - uterine distortion (fibroids)
  - intra-amniotic infection (fever or prolonged ROM)
  - bladder distension (preventing uterine contraction)

2. Tissue
- retained placental products (membranes, cotyledon, or succenturiate lobe)
- retained blood clots in an atonic uterus
- gestational trophoblastic neoplasia
- abnormal placentation (e.g. placenta accreta)

3. Trauma
- laceration (vagina, cervix, or uterus), episiotomy, hematoma (vaginal, vulvar, or retroperitoneal), uterine rupture, and uterine inversion

4. Thrombin
- coagulopathy (pre-existing or acquired)
  - most identified prior to delivery (low platelets increases risk)
  - includes hemophilia, DIC, ITP, TTP, and VWD (most common)
  - therapeutic anti-coagulation

Investigations
- assess degree of blood loss and shock by clinical exam
- explore uterus and lower genital tract for evidence of atony, retained tissue, or trauma
- may be helpful to observe red-topped tube of blood – no clot in 7-10 min indicates coagulation problem

Management
- ABCs, call for help
- 2 large bore IVs, run crystalloids wide open
- CBC, coagulation profile, fibrinogen, cross and type packed RBCs
- treat underlying cause
- Foley catheter to empty bladder and monitor urine output

Medical Therapy
- oxytocin 10 IU IM is preferred in low-risk vaginal deliveries, oxytocin IV infusion (20-40 IU in 1000 mL crystalloid at 150 mL/h) is an acceptable alternative; oxytocin 5-10 IU IV bolus (20-40 IU in 250 mL crystalloid) can be used after vaginal birth, but not with elective CD
- carbetocin, a long-acting oxytocin, 100 μg IV bolus over 1 min for elective CD or 100 μg IM for vaginal deliveries with 1 risk factor for PPH (instead of a continuous oxytocin infusion)
- methylergonovine maleate (Ergotamine®) 0.25 mg IM/slow IV q2 h up to 1.25 mg; can be given as IV bolus of 0.125 mg (contraindicated in HTN)
- carboprost (Hemabate®), a synthetic PGF-1α analog, 250 μg IM/IMM q15 min to max 2 mg (major prostaglandin side effects and contraindicated in cardiovascular, pulmonary, renal, and hepatic dysfunction)
- misoprostol 600-800 μg PO/SL (faster) or PR/PV (side effect: pyrexia if >600 μg)
- tranexamic acid (Cyklokapron®), an antifibrinolytic, 1 g IV

Local Control
- bimanual massage: elevate the uterus and massage through patient's abdomen
- uterine packing (mesh with antibiotic treatment)
- Bakri Balloon for tamponade: may slow hemorrhage enough to allow time for correction of coagulopathy or for preparation of an OR

Surgical Therapy (Intractable PPH)
- D&C (beware of vigorous scraping, which can lead to Asherman's syndrome)
- embolization of uterine artery or internal iliac artery by interventional radiologist
- laparotomy with bilateral ligation of uterine artery (may be effective), ovarian artery, or internal iliac artery ± compression sutures (B-Lynch or Cho sutures)
- hysterectomy last option, with angiographic embolization if post-hysterectomy bleeding

Retained Placenta

Definition
- placenta undelivered after 30 min postpartum

Etiology
- placenta separated but not delivered
- abnormal placental implantation (placenta accreta, placenta increta, and placenta percreta)

Risk Factors
- placenta previa, prior CD, post-pregnancy curettage, prior manual placental removal, and uterine infection

Clinical Features
- risk of PPH and infection

Investigations
- explore uterus
- assess degree of blood loss

Management
- 2 large bore IVs, type and screen
- Brandt maneuver (firm traction on umbilical cord with one hand applying suprapubic pressure cephalad to avoid uterine inversion by holding uterus in place)
- oxytocin 10 IU in 20 mL normal saline into umbilical vein
- manual removal if above fails
- D&C if required (U/S guidance if available)
- cefazolin 2 g IV if manual removal or D&C

Uterine Inversion

Definition
- inversion of the uterus through cervix ± vaginal introitus

Etiology/Epidemiology
- often iatrogenic (excess cord traction with fundal placenta)
- excessive use of uterine tocolytics
- more common in grand multiparous women (lax uterine ligaments)
- 1 in 1500 to 1 in 2000 deliveries

Clinical Features
- can cause profound vasovagal response with bradycardia, vasodilation, and hypovolemic shock
- shock may be disproportionate to maternal blood loss

Management
- urgent management essential, call anesthesia
- ABCs: initiate IV crystalloids
- can use tocolytic drug (see *Preterm Labour*, OB17) or nitroglycerin IV to relax uterus and aid replacement
- replace uterus without removing placenta
- remove placenta manually and withdraw slowly
- IV oxytocin infusion (only after uterus replaced)
- re-explore uterus
- may require general anesthetic ± laparotomy

Postpartum Pyrexia

Definition
- fever >38°C on any two of the first 10 d postpartum, except the 1st day

Etiology
- endometritis
- wound infection (check CD and episiotomy sites)
- mastitis/breast engorgement
- UTI
- atelectasis
- pneumonia
- DVT or pelvic thrombophlebitis

Etiology of Postpartum Pyrexia

B-5W
Breast: engorgement, mastitis
Wind: atelectasis, pneumonia
Water: UTI
Wound: episiotomy, CD site infection
Walking: DVT, thrombophlebitis
Womb: endometritis

Investigations
- detailed history and physical exam, relevant cultures
- for endometritis: blood and genital cultures
- serum lactic acid for early detection of sepsis

Treatment
- depends on etiology
  - infection: empiric antibiotics, adjust when sensitivities available
- endometritis: clindamycin + gentamicin IV
- mastitis: cloxacillin or cephalexin
- wound infection: cephalexin + frequent sitz baths for episiotomy site infection
  - DVT: anticoagulants
- prophylaxis against post-CD endometritis: administer cefazolin 2-4 g IV (based on BMI) 30 min prior to skin incision

ENDOMETRITIS
- **definition**: inflammation of the endometrium most commonly due to infection
- **clinical features**: fever, chills, abdominal pain, uterine tenderness, foul-smelling vaginal discharge, or lochia
- **treatment**: depends on infection severity; oral antibiotics if well, IV antibiotics with hospitalization in moderate to severe cases

Risk Factors for Endometritis
CD, intrapartum chorioamnionitis, prolonged labour, prolonged ROM, and multiple vaginal examinations

VENOUS THROMBOEMBOLISM
- see *Venous Thromboembolism*, OB32

Mastitis

- definition: inflammation of mammary glands
- must rule out inflammatory carcinoma, as indicated
- differentiate from mammary duct ectasia: mammary duct(s) beneath nipple clogged and dilated ± ductal inflammation ± nipple discharge (thick, grey to green), often postmenopausal women

Table 22. Lactational vs. Non-Lactational Mastitis

	Lactational	Non-Lactational
Epidemiology	More common than non-lactational Often 2-3 wk postpartum	Periductal mastitis most common Mean age 32 yr
Etiology	*S. aureus*	May be sterile May be infected with *S. aureus* or other anaerobes Smoking is risk factor May be associated with mammary duct ectasia
Symptoms	Unilateral localized pain Tenderness Erythema	Subareolar pain May have subareolar mass Discharge (variable colour) Nipple inversion
Treatment	Heat or ice packs Continued nursing/pumping Antibiotics (cloxacillin/cephalexin) (erythromycin if penicillin-allergic)	Broad-spectrum antibiotics and I&D Total duct excision (definitive)
Abscess	Fluctuant mass Purulent nipple discharge Fever, leukocytosis Discontinue nursing, IV antibiotics (nafcillin/oxacillin), I&D usually required	If mass does not resolve, fine-needle aspiration to exclude cancer and U/S to assess presence of abscess Treatment includes antibiotics, aspiration, or I&D (tends to recur) May develop mammary duct fistula A minority of non-lactational abscesses may occur peripherally in breast with no associated periductal mastitis (usually *S. aureus*)

Postpartum Mood Alterations

POSTPARTUM BLUES

- 40-80% of new mothers, onset 3-10 d postpartum; extension of the "normal" hormonal changes and adjustment to a new baby
- self-limited, should resolve by 2 wk
- manifested by mood lability, depressed affect, increased sensitivity to criticism, tearfulness, fatigue, irritability, poor concentration/despondency, anxiety, and insomnia

POSTPARTUM DEPRESSION

- **definition**: major depression occurring in a woman within 6 mo of childbirth (see Psychiatry, PS14)
- **epidemiology**: 10-15%, risk of recurrence 50%
- **risk factors:**
  - personal or family history of depression (including PPD)
  - prenatal depression or anxiety
  - stressful life situation
  - poor support system
  - unwanted pregnancy
  - colicky or sick infant
- **clinical features**: suspect if the "blues" last beyond 2 wk, or if the symptoms in the first 2 wk are severe (e.g. extreme disinterest in the baby, suicidal or homicidal/infanticidal ideation)
- **assessment**: Edinburgh Postnatal Depression Scale or others
- **treatment**: antidepressants, psychotherapy, supportive care, and electroconvulsive therapy if refractory
- **prognosis**: interferes with bonding and attachment between mother and baby, so it can have long-term effects

POSTPARTUM PSYCHOSIS

- **definition**: acute psychotic episode triggered by the complex psychosocial stressors and hormonal changes that occur following childbirth. Symptoms usually present within the first 2 wk but can last for months
- **epidemiology**: rare (0.2%), but 50% risk of recurrence in next pregnancy if experienced in previous pregnancy. Increased risk in individuals with bipolar disorder, schizoaffective disorder, schizophrenia, or other psychotic illness, personal or family history of postpartum psychosis
- **treatment**: psychiatric emergency as risk of infanticide. Typically requires hospitalization, mood stabilizer, and antipsychotics

Postpartum Care

Postpartum Office Visit at 6 Weeks

Care of Mother (The 10 Bs)

- **B**e careful: do not use douches or tampons for 4-6 wk post-delivery
- **B**e fit: encourage gradual increases in walking, Kegel exercises
- **B**irth control: assess for use of contraceptives
- **B**reastfeeding is not as effective as other methods of birth control (see Gynaecology, GY15, for more detail about different contraceptive options postpartum)
  - lactational amenorrhea approved by WHO for up to 6 mo if meets criteria: 1) amenorrhea; 2) fully or nearly fully breastfeeding (no interval of >4-6 h between breastfeeds); and 3) <6 mo postpartum
- **B**ladder: assess for urinary incontinence, maintain high fluid intake
- **B**lood pressure: especially if gestational HTN
- **B**lood tests: CBC (for anemia if had PPH, TSH if subclinical hypothyroidism in pregnancy, 75g OGTT if GDM)
- **B**lues: (see *Postpartum Mood Alterations*, OB49)
- **B**owel: fluids and high-fibre foods, bulk laxatives; for hemorrhoids/perineal tenderness: pain meds, doughnut cushion, sitz baths, and ice compresses
- **B**reast and pelvic exam: watch for Staphylococcal or Streptococcal mastitis/abscess, ± Pap smear at 6 wk if due for screening

The acronym "**BUBBLES**" for what to ask about when rounding on postpartum care. Modify this for CD or vaginal delivery

Baby care and breastfeeding–- Latch? Amount?
Uterus – Firm or boggy?
Bladder function – Voiding well? Dysuria?
Bowel function – Passing gas or stool? Constipated?
Lochia or discharge – Any blood?
Episiotomy/laceration/incision – Pain controlled?
Symptoms of VTE – Dyspnea? Calf pain?

Physiological Changes Postpartum

- uterus weight rapidly diminishes through catabolism, cervix loses its elasticity and regains firmness
  - should involute ~1 cm below umbilicus per day in first 4-5 d, reaches non-pregnant state in 4-6 wk postpartum
- ovulation resumes in ~45 d after giving birth, non-lactating women usually ovulate sooner than lactating women
- lochia: normal vaginal discharge postpartum, uterine decidual tissue sloughing
  - decreases and changes in colour from red (lochia rubra; presence of erythrocytes, 3-4 d) ➔ pale (lochia serosa) ➔ white/yellow (lochia alba; residual leukorrhea) over 3-6 wk
- foul-smelling lochia suggests endometritis

Breastfeeding Problems

- inadequate milk: consider domperidone
- breast engorgement: cool compress, manual expression/pumping
- nipple pain: clean milk off nipple after feeds, moisturizer, topical steroid if needed
- mastitis: treat promptly (see *Postpartum Pyrexia*, OB48)
- inverted nipples: makes feeding difficult
- maternal medications: may require paediatric consultation (see *Breastfeeding and Drugs*, OB51)

Bladder Dysfunction

- pelvic floor prolapse can occur after vaginal delivery
- stress or urge urinary incontinence common
- increased risk with instrumental delivery or prolonged second stage
- conservative management for stress and urge incontinence: pelvic floor retraining with Kegel exercises/pelvic physiotherapy, vaginal cones or pessaries, and lifestyle modifications (e.g. limit fluid, caffeine intake, local vaginal estrogen in breastfeeding women to strengthen vaginal mucosa)

Puerperal Pain

- "after pains" common in first 3 d due to uterine contractions; encourage simple analgesia
- ice packs and sitz baths can be used on perineum if painful
- encourage regular analgesia and stool softener

Breastfeeding and Drugs

Table 23. Drug Safety During Breastfeeding

Safe During Breastfeeding	Contraindicated When Breastfeeding
Analgesics (e.g. acetaminophen, NSAIDs) Anticoagulants (e.g. heparin) Antidepressants (e.g. sertraline, fluoxetine, tricyclic antidepressants) Antiepileptics (e.g. phenytoin, carbamazepine, valproic acid) Antihistamines Antimicrobials (e.g. penicillins, aminoglycosides, cephalosporins) β-adrenergics (e.g. propanolol, labetalol) Insulin Steroids OCP (low dose) – although estrogen-containing OCPs may decrease breast milk production	Chloramphenicol (bone marrow suppression) Cyclophosphamide (immune system suppression) Sulphonamides (in G6PD deficiency, can lead to hemolysis) Nitrofurantoin (in G6PD deficiency, can lead to hemolysis) Tetracycline Lithium Phenindione Bromocriptine Anti-neoplastics and immunosuppressants Psychotropic drugs (relative contraindication)

Common Medications

Table 24. Common Medications

Drug Name (Brand Name)	Dosing Schedule	Indications/Comments
betamethasone valerate (Celestone®)	12 mg IM q24 h x 2 doses	Enhancement of fetal pulmonary maturity for PTL
carboprost (Hemabate®)	0.25 mg IM/IMM q15 min Max 2 mg	Treatment of uterine atony
cefazolin	2 g IV then 1 g q8 h	GBS prophylaxis (penicillin allergic and not at risk for anaphylaxis)
clindamycin	900 mg IV q8 h	Used in endometritis
dexamethasone	6 mg IM q12 h x 4 doses	Enhancement of fetal pulmonary maturity for PTL
dinoprostone (Cervidil®: PGE2 impregnated thread)	10 mg PV (remove after 12 h) Max 3 doses	Induction of labour Advantage: can remove if tachysystole
doxylamine succinate (Diclectin®)	2 tablets qhs + 1 tablet qam + 1 tablet qpm Max 8 tablets /d	Each tablet contains 10 mg doxylamine succinate with vitamin B_6 Used first-line for N/V in pregnancy, including hyperemesis gravidarum
erythromycin	250 mg PO q6 h x 10 d	To prolong pregnancy and decrease maternal and neonatal morbidity for patients who are not in labour in PPROM
folic acid	0.4-1 mg PO once daily x 1-3 mo preconception and T1 4 mg PO once daily with past Hx of NTD/high risk for NTD	Prevention of ONTD
methylergonovine maleate (Ergotamine®)	0.25 mg IM/slow IV q2 h up to 1.25 mg or IV bolus 0.125 mg	Treatment of uterine atony
misoprostol (Cytotec®)	600-1000 µg PR x 1 dose 400 µg PO/SL x 1 dose or 800 µg PV x 1 dose 3-7 d after methotrexate	For treatment of PPH For medical abortion/retained products of conception
oxytocin (Pitocin®)	0.5-2.0 mU/min IV or 10 IU/L normal saline increase by 1-2 mU/min q20-60 min 10 IU IM at delivery of anterior shoulder (or after delivery of placenta) 20 IU/L normal saline or Ringer's Lactate IV continuous infusion	Induction/augmentation of labour Prevention of uterine atony Treatment of uterine atony
penicillin G	5 million IU IV, then 2.5 million IU IV q4 h until delivery	GBS prophylaxis
PGE2 gel (Prostin® gel)	0.5 mg PV q6-12 h; Max 3 doses	Induction of labour
Rh IgG (Rhogam®)	300 µg IM x 1 dose	Given to Rh-negative women Routinely at 28 wk GA Within 72 h of birth of Rh+ fetus Positive Kleihauer-Betke test With any invasive procedure in pregnancy Ectopic pregnancy Antepartum hemorrhage and first trimester bleeding Miscarriage or therapeutic abortion (dose: 50 µg IM only)

Landmark Obstetrics Trials

Trial Name	Reference	Clinical Trial Details
PRETERM LABOUR		
Meis Trial	NEJM 2003; 348:2379-2385	**Title**: Prevention of Recurrent Preterm Delivery by 17 Alpha-Hydroxyprogesterone Caproate **Purpose**: Confirm the results of several small trials that have suggested that the use of alpha-hydroxyprogesterone caproate (17P) may reduce the risk of recurrent preterm delivery. **Methods**: Double-blind placebo-controlled trial involved pregnant women with a history of spontaneous preterm delivery. Women received either weekly injections until delivery, or 36 weeks of gestation, of 250mg 17P or of an inert placebo. **Results**: Treatment with 17P significantly reduced the risk of delivery at less than 37 weeks (36.3% vs. 54.9%), less than 35 weeks (20.6% vs. 30.7%), and less than 32 weeks (11.4% vs. 19.6%). Infants of women treated with 17P had lower rates of enterocolitis, hemorrhage, and need for supplemental oxygen. **Conclusions**: Weekly injections of 17P resulted in substantial reductions in the rate of recurrent preterm delivery among women and reduced the likelihood of several complications in the infants.
MULTI-FETAL GESTATION		
Twin Birth Study	NEJM 2013; 369:1295-1305	**Title**: A Randomized Trial of Planned Cesarian or Vaginal Delivery for Twin Pregnancy **Purpose**: Twin births are associated with a higher risk of adverse perinatal outcomes. It is unclear whether cesarian section results in lower risk of negative outcomes than vaginal delivery in twin pregnancies. **Methods**: Women between 32 – 38+6 days of gestation with a twin pregnancy and with the first twin in the cephalic position were randomly assigned to planned c-section or planned vaginal delivery. **Results**: There was no significant difference in the outcomes between the planned c-section and the planned vaginal delivery group (2.2% and 1.9%, respectively; odds ratio with planned c-section 1.16; 95% confidence interval, 0.77 to 1.74; P=0.49). **Conclusion**: There was no benefit from planned c-section compared with planned vaginal delivery of twins between 32 and 38 weeks of gestation if the first twin was in the cephalic position.

Acronyms

AION	anterior ischemic optic neuropathy
AMD	age-related macular degeneration
BCVA	best-corrected visual acuity
BRAO	branch retinal artery occlusion
BRVO	branch retinal vein occlusion
CDR	cup-to-disc ratio
CMV	cytomegalovirus
CRAO	central retinal artery occlusion
CRVO	central retinal vein occlusion
D	diopter
DR	diabetic retinopathy
EBV	Epstein-Barr virus
EOM	extraocular movement
FML	fluorometholone
GAT	Goldmann applanation tonometry
GCA	giant cell arteritis
GPA	granulomatosis with polyangiitis
GPC	giant papillary conjunctivitis
HRT	Heidelberg retinal tomography
INO	internuclear ophthalmoplegia
IOL	intraocular lens
IOP	intraocular pressure
LASIK	laser-assisted *in situ* keratomileusis
MS	multiple sclerosis
OCT	optical coherence tomography
OHT	ocular hypertension
PACG	primary angle-closure glaucoma
PDR	proliferative diabetic retinopathy
PDT	photodynamic therapy
PERRLA	pupils equal, round, and reactive to light and accommodation
POAG	primary open-angle glaucoma
PRK	photorefractive keratectomy
PVD	posterior vitreous detachment
RA	rheumatoid arthritis
RAPD	relative afferent pupillary defect
RD	retinal detachment
ROP	retinopathy of prematurity
RPE	retinal pigment epithelium
SPK	superficial punctate keratitis
TED	thyroid eye disease
TIA	transient ischemic attack
VA	visual acuity
VEGF	vascular endothelial growth factor
YAG	yttrium aluminum garnet

Basic Anatomy Review

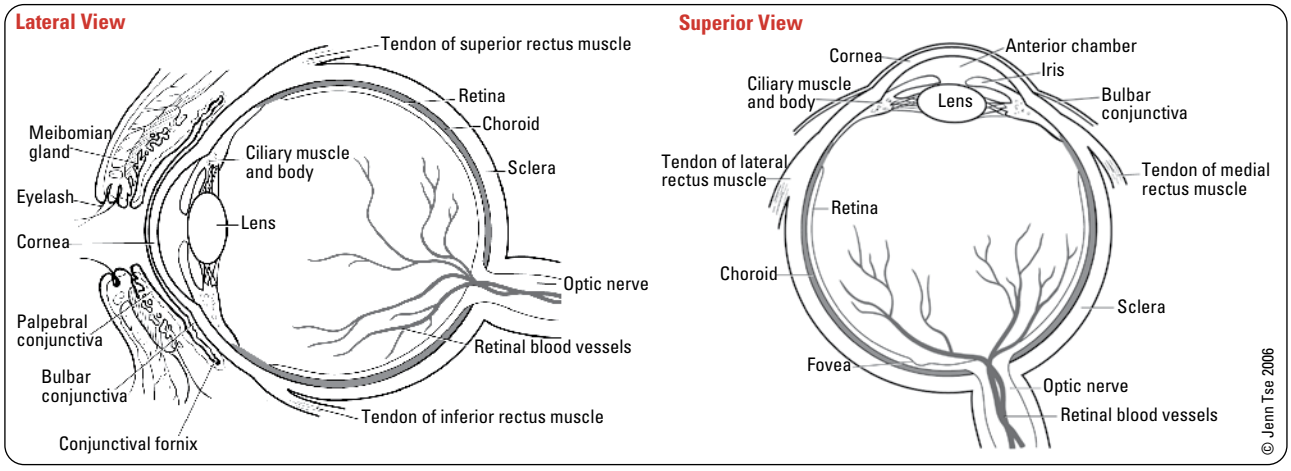

Figure 1. Anatomy of the eye

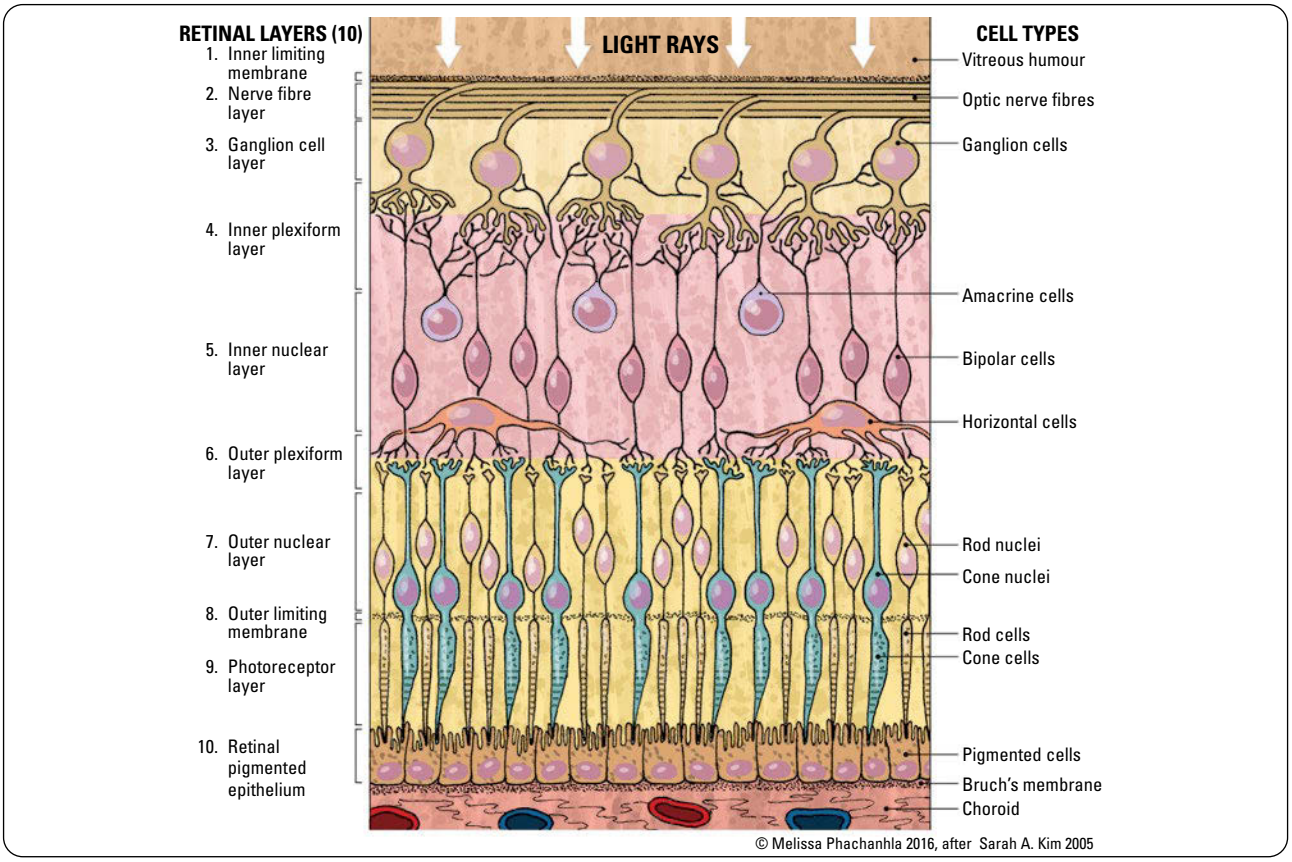

Figure 2. Layers of the retina

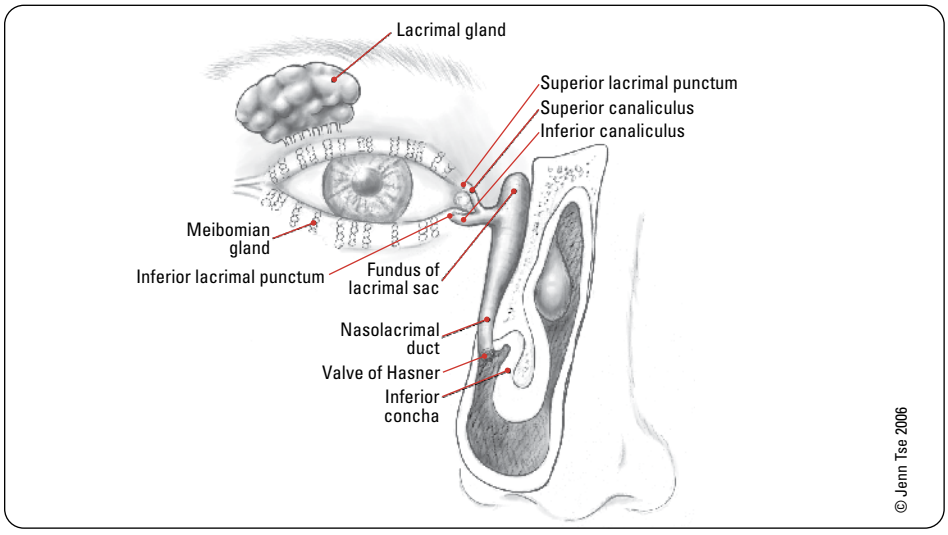

Figure 3. Tear drainage from the eye (lacrimal apparatus)

Differential Diagnoses of Common Presentations

Loss of Vision

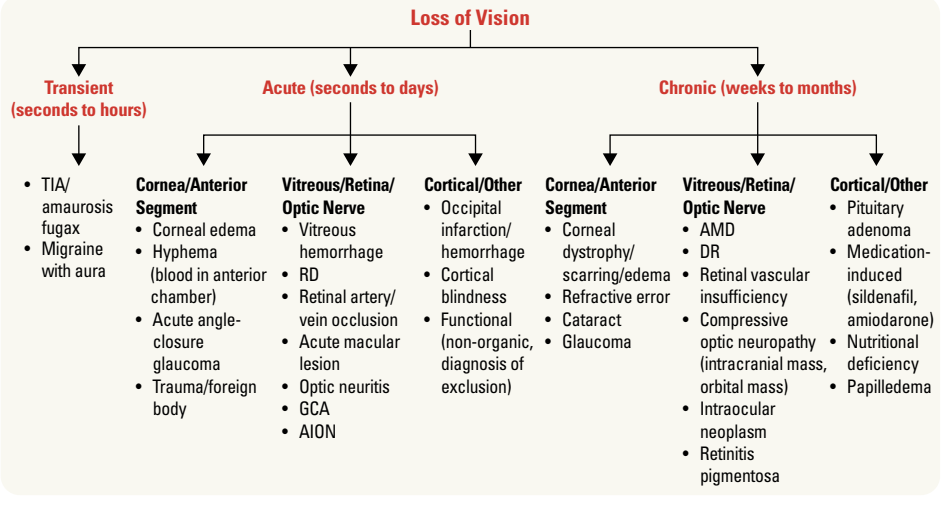

Figure 4. Loss of vision

Red Eye

Table 1. Common Causes of Red Eye

Common Causes		
Lids/Orbit/Lacrimal System	**Cornea**	**Other**
Hordeolum/chalazion	Foreign body (including contact lens)	Trauma
Blepharitis	Keratitis	Postoperative endophthalmitis
Entropion/ectropion	Abrasion, laceration	Pharmacologic (e.g. prostaglandin analogues)
Foreign body/laceration	Ulcer	
Dacryocystitis/dacryoadenitis		
Conjunctiva/Sclera	**Anterior chamber**	
Subconjunctival hemorrhage	Anterior uveitis (iritis, iridocyclitis)	
Conjunctivitis	Acute glaucoma	
Dry eyes	Hyphema (blood in anterior chamber)	
Pterygium	Hypopyon (pus in anterior chamber)	
Episcleritis/scleritis		
Preseptal/orbital cellulitis		

Table 2. Common Differential Diagnoses of Red Eye

	Conjunctivitis	Acute Iritis	Acute Glaucoma	Keratitis (Corneal Ulcer)
Discharge	Bacterial: purulent Viral: serous/mucoid Allergic: mucoid	No	Clear	Bacterial: ± purulent
Pain	±	++ (dull/achy)	+++ (nausea)	++ (sharp)
Photophobia	No	+++	+	++
Blurred Vision	No	++	+++	Varies
Pupil	Normal	Smaller	Fixed in mid-dilation	Same or smaller
Injection	Diffuse conjunctival injection involving the bulbar conjunctiva for 360° + palpebral or tarsal conjunctiva	Ciliary flush (peri-limbal)	Conjunctival injection	Possible conjunctival injection
Cornea	Normal (subepithelial infiltrates in adenoviral conjunctivitis)	Keratic precipitates	Cloudy	Infiltrate, edema, and may have keratic precipitates
IOP	Normal	Varies	Increased markedly	Normal or slightly decreased
Anterior Chamber	Normal	+++ Cells and flare	Shallow	Cells and flare or normal, and may have hypopyon
Nausea and Vomiting	No	No	+++	No
Other	Large, tender pre-auricular node(s) if viral	Posterior synechiae	Coloured haloes	

Not every red eye has conjunctivitis

Ocular Pain

- differentiate from eye fatigue (asthenopia)
- ocular surface disease
- herpes zoster prodrome
- trauma/foreign body
- blepharitis
- keratitis corneal abrasion/ulcer
- acute glaucoma
- acute uveitis
- scleritis
- episcleritis
- optic neuritis

Floaters

- PVD (often secondary to age-related vitreous syneresis)
- vitreous hemorrhage
- retinal tear/detachment
- intermediate uveitis (pars planitis)
- posterior uveitis (chorioretinitis)

Flashes of Light (Photopsia)

- PVD (often secondary to age-related vitreous syneresis)
- retinal tear/detachment
- migraine with aura

Photophobia (Severe Light Sensitivity)

- corneal abrasion, corneal ulcer
- keratitis
- acute angle-closure glaucoma
- iritis meningitis/encephalitis
- migraine
- subarachnoid hemorrhage (SAH)

Diplopia (Double Vision)

Table 3. Common Causes of Diplopia

Binocular Diplopia	Monocular Diplopia
Definition	
Occurs with both eyes open, eliminated with occlusion of either eye	Occurs with one eye open, remains with occlusion of unaffected eye
Causes	
Decompensated congenital strabismus	Optical factors: refractive error/astigmatism
Ocular motor nerve dysfunction: III, IV, VI nerve palsy	Mechanical process: dislocated lens, postoperative sequelae (cataract surgery, peripheral laser iridotomy)
Neuromuscular junction disease: myasthenia gravis, botulism	Other: strands of mucus in tear film, keratoconus
Mechanical process: muscle restriction/entrapment, TED	
Supranuclear Causes: skew deviation, dorsal midbrain syndrome	

Ocular Problems in the Contact Lens Wearer

- solution hypersensitivity
- tight lens syndrome
- corneal abrasion
- GPC/contact lens allergy
- SPK from dry eyes
- limbal stem cell deficiency
- corneal neovascularization
- sterile corneal infiltrates (immunologic)
- infected ulcers (Pseudomonas, Acanthamoeba)

Ocular Emergencies

These require urgent ophthalmology consultation for management

Sight-Threatening
- lid laceration
- globe rupture
- chemical burn
- corneal ulcer
- gonococcal conjunctivitis
- acute iritis
- acute glaucoma
- CRAO
- intraocular foreign body
- RD (especially when macula threatened)
- endophthalmitis
- GCA

Life-Threatening
- proptosis (rule out cavernous sinus fistula or thrombosis)
- cranial nerve (CN) III palsy with dilated pupil (rule out intracranial aneurysm or externally compressive neoplastic lesion)
- papilledema (elevated or increased ICP workup)
- orbital cellulitis
- leukocoria: white pupillary reflex (absent red reflex: rule out retinoblastoma in children)

Example 1

$\underline{SC}$ V 20/40 −1
20/80 +2 → 20/25 PH

Example 2

$\underline{CC}$ V CF 3'
HM

Note: RIGHT EYE visual acuity always listed on top.

V	Vision
SC	Without correction
CC	With correction
20/40 -1	All except one letter of 20/40
20/80+2	All of 20/80 plus two letters of 20/70
PH	Visual acuity with pinhole correction
CF	Counting fingers
HM	Hand motion

Figure 5. Ophthalmology nomenclature for visual acuity

OD = oculus dexter = right eye
OS = oculus sinister = left eye
OU = oculus uterque = both eyes

The Ocular Examination

VISUAL ACUITY

Visual Acuity – Distance
- Snellen VA = testing distance (usually 20 ft or 6 m) / smallest line patient can read on the chart
  - e.g. 20/40 = what the patient can see at 20 feet away (numerator) is what a "normal" person can see at 40 feet away (denominator)
- distance VA should be tested with distance glasses on in order to obtain BCVA
- testing hierarchy for low vision: Snellen VA (20/x) ➔ counting fingers at a given distance (CF) ➔ hand motion (HM) ➔ light perception with projection (LP with projection) ➔ light perception (LP) ➔ no light perception (NLP)
- legal blindness is a BCVA that is ≤20/200 in best eye

Snellen VA of 20/20 equates to "normal" vision

Normal Infant and Child Visual Acuity Equivalent
- 6-12 mo: 20/120
- 1-2 yr: 20/80
- 2-4 yr: 20/20

- minimum visual requirements to operate a non-commercial automobile in Ontario are: 20/50 BCVA with both eyes open and examined together, 120° continuous horizontal visual field, and 15° continuous visual field above and below fixation

Visual Acuity – Near
- use pocket vision chart (Rosenbaum Pocket Vision Screener)
- record Jaeger (J) or Point number and testing distance (usually 30 cm) e.g. J2 @ 30 cm
- conversion to distance VA possible (e.g. immobile patient, no distance chart available)

Visual Acuity for Infants, Children, Non-English Speakers, and Dysphasics
- newborns
  - VA cannot be tested conventionally
- 3 mo-3 yr: can usually only assess visual function, not acuity
  - test each eye for fixation symmetry using an interesting object
  - normal function noted as "CSM" = central, steady, and maintained
- 3 yr until alphabet known
  - pictures or letter cards/charts such as HOTV or Sheridan-Gardiner test (children point to optotypes on a matching card)
  - tumbling "E" chart

COLOUR VISION
- test with Ishihara pseudoisochromatic plates
- record number of correctly identified plates presented to each eye (usually 14 plates)
- important for testing optic nerve function and identifying an optic neuropathy (e.g. optic neuritis)
- note: red-green colour blindness is sex-linked and occurs in 7-10% of males

VISUAL FIELDS
- estimation of visual field loss: test by confrontation (4 quadrants, each eye tested separately)
- accurate, quantifiable assessment: automated visual field testing (Humphrey or Goldmann) or Tangent Screen
- AMD monitoring: Amsler grid (each eye tested separately) to check for central or paracentral scotomas (blind spots) and distortion
- see Neurology, N15 for visual field defects

PUPILS
- use reduced room illumination with patient focusing on distant, fixed object to prevent near reflex
- examine pupils for shape, size, symmetry, and reactivity to light (both direct and consensual response)
- test for RAPD with swinging flashlight test, check by reverse RAPD test if one pupil non-reactive
- test pupillary constriction portion of near reflex by bringing object close to patient's nose
- "normal" pupil testing often noted as PERRLA (pupils equal, round, reactive to light and accommodation)

ANTERIOR CHAMBER DEPTH
- shine light tangentially from temporal side
- if >2/3 of nasal side of iris in shadow ➔ shallow anterior chamber
- gonioscopy is the gold-standard for assessing anterior chamber depth

The Van Herick Method (Slit-Lamp technique)
- shine thin-angled slit beam onto the peripheral cornea of each eye, view at a 60° angle from the beam
- estimate anterior chamber depth using the ratio of corneal slit beam thickness to the space between the posterior cornea and the iris
- ratios ≤1/4 implies risk of occludable angle; however, if >1/4, this does not rule out risk

EXTRAOCULAR MUSCLES

Alignment
- Hirschberg corneal reflex test
  - examine in primary position of gaze (i.e. straight ahead) with patient focusing on distant object
  - shine light into patient's eyes from ~30 cm away
  - corneal light reflex should be at the same position on each cornea
- strabismus testing as indicated (cover test, cover-uncover test, prism testing) (see *Strabismus*, OP37)

Movement
- examine movement of eyeball through six cardinal positions of gaze
- identify if there is limitation of eye movement in each position of gaze
- observe for horizontal, vertical, or rotatory nystagmus (rhythmic, oscillating movements of the eye)
- resolving horizontal nystagmus at end-gaze is usually normal

Diplopia
- see Neurology, N16

Test pupils using an ophthalmoscope focused on the red reflex; this will provide a better view than using a penlight

4 Ps of Inspection
Pupil: shape, size, symmetry
Position: esotropia, exotropia, central
Ptosis
Primary nystagmus

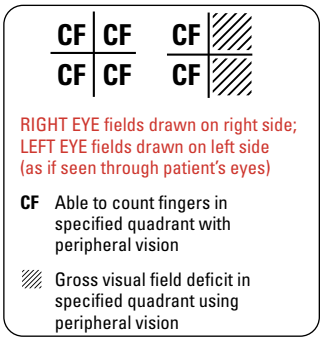

Figure 6. Ophthalmology nomenclature for visual fields by confrontation

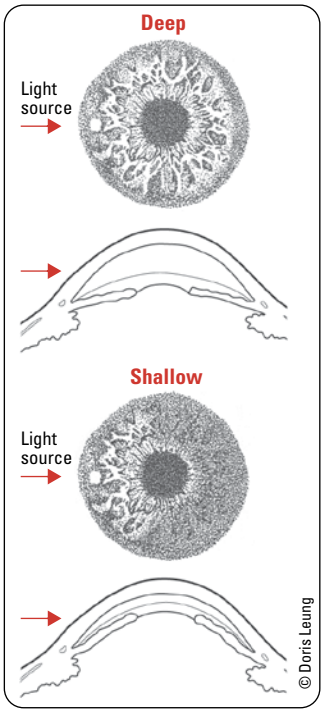

Figure 7. Estimation of anterior chamber depth

SLIT-LAMP EXAMINATION

Ocular Adnexa
- lids, lashes, and lacrimal system

Anterior Segment
- conjunctiva/sclera
- cornea
  - fluorescein dye: stains de-epithelialized cornea; dye appears fluorescent green with cobalt blue filtered light
  - Rose Bengal dye: stains devitalized corneal epithelium; dye appears red
- anterior chamber (cells, flare) and angle (Van Herick method)
- iris/pupil
- lens (assess for cataract)
- anterior vitreous

Posterior Segment (requires 78 D or 90 D lens)
- vitreous
- optic disc (colour, CDR ratio, sharpness of disc margin)
- macula (~1.5-2 disc diameters temporal to disc), fovea (foveal light reflex)
- retinal vessels
- retinal background

TONOMETRY
- measurement of IOP
- normal range is 9-21 mmHg (average 15 mmHg)
- IOP has diurnal variation, so always record the time of day at which the measurement was taken
- commonly measured by:
  - GAT: clinical gold standard, performed using the slit-lamp with prism tip
  - Tono-Pen®: benefits are portability and use of disposable probe tips; use when GAT is inaccurate, such as when the cornea is scarred or asymmetric
  - iCare®: uses a disposable light-weight probe that contacts the cornea briefly, without anesthetic required; used especially in paediatrics
  - non-contact tonometer (NCT): air puff, least reliable
- use topical anesthetic for GAT and Tono-Pen®; apply fluorescein dye and use cobalt blue light for GAT

DIRECT OPHTHALMOSCOPY
- best performed with pupils dilated (for list of mydriatic and cycloplegic drugs see Table 13, OP44)
  1. assess red reflex
     - light reflected off the retina produces a "red reflex" when viewed from ~1 foot away
     - anything that interferes with the passage of light will diminish the red reflex (e.g. large vitreous hemorrhage, cataract)
     - white reflex indicates leukocoria, see *Leukocoria*, OP40
  2. examine the posterior segment of the eye
     - vitreous
     - optic disc (colour, CDR, sharpness of disc margin)
     - macula (~1.5-2 disc diameters temporal to disc), fovea (foveal light reflex)
     - retinal vessels
     - retinal background
- contraindications to pupillary dilatation
  - shallow anterior chamber – can precipitate acute angle-closure glaucoma
  - iris-supported anterior chamber lens implant
  - potential neurologic abnormality requiring pupil evaluation
  - use caution with cardiovascular disease – mydriatics may cause tachycardia and HTN

Optics

REFRACTION
- two techniques used
  - flash/streak retinoscopy: refractive error determined objectively by the examiner using lenses and retinoscope
  - manifest: subjective trial using loose lenses or a phoropter (device the patient looks through that is equipped with lenses)
    - cycloplegic: manifest refraction with accommodation temporarily paralyzed with cycloplegics

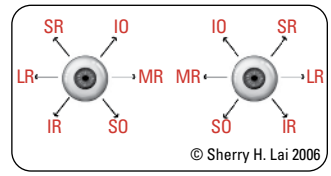

Figure 8. Diagnostic positions of gaze for isolated primary actions of extraocular muscles

Extraocular Muscle Innervations

LR6 SO4 AE3
Lateral **R**ectus via CN **VI**
Superior **O**blique via CN **IV**
All **E**lse via CN **III** (superior, medial, and inferior rectus, inferior oblique)

Aqueous Flare
- Resembles "headlights in fog" (Tyndall effect) in a beam of light
- Results from increased aqueous turbidity secondary to protein leaking from blood vessels
- Distinguish from aqueous cells (individual cells in anterior chamber)

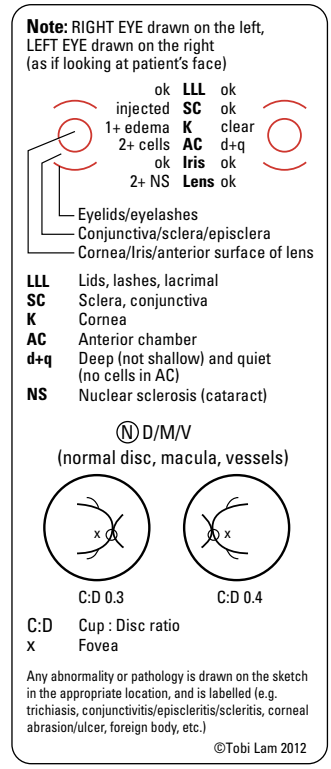

Figure 9. Slit-lamp examination note

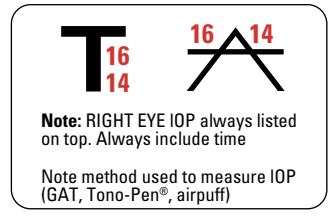

Figure 10. Tonometry

- a typical lens prescription would contain:
  - sphere power in diopter (measurement of refractive power of lens, equal to reciprocal of focal length in metres)
  - cylinder power in diopter to correct astigmatism
  - axis of cylinder in degrees
  - "add" (bifocal/progressive reading lens) for presbyopes
  - e.g. -1.50 + 1.00 x 120°, add +2.00

Central Corneal Thickness (CCT)
Average CCT = 550 µm
By GAT, IOP is over-estimated with thick corneas and under-estimated with thin corneas

LASER REFRACTIVE EYE SURGERY

- permanently alters corneal refractive properties by ablating tissue to change curvature of the cornea
- used for correction of myopia, hyperopia, and astigmatism
- common types include PRK and LASIK
- potential risks/side-effects: infection, under/overcorrection, increased glare/halo perception at night, corneal haze (PRK only), dry eyes (more common in LASIK than PRK), regression, corneal ectasia, and flap complications such as free cap (loss of flap), traumatic flap dislocations, buttonhole flap, and epithelial ingrowth (LASIK only)

Table 4. Optics

	Pathophysiology	Clinical Features	Treatment	Complications
Emmetropia	Image of distant objects focuses directly on the retina	No refractive error		
Myopia	Globe too long relative to refractive mechanisms, or refractive mechanisms too strong Light rays from distant object focus in front of retina → blurring of (distance) vision	"Nearsightedness" Usually presents in 1st or 2nd decade, stabilizes in 2nd and 3rd decade; rarely begins after age 25 except in patients with DM-induced cataracts Blurring of distance vision; near vision usually unaffected due to accommodation Prevalence: 30-40% in U.S. population; higher among Asians	Correct with negative diopter/concave/ "negative" lenses to diverge light rays Refractive eye surgery	Retinal tear/detachment, chorioretinal atrophy, myopic maculoschisis leading to formation of macular hole, open-angle glaucoma
Hyperopia	Globe too short relative to refractive mechanisms, or refractive mechanisms too weak Light rays from distant object focus behind retina → blurring of near ± distant vision May be developmental or due to any etiology that shortens globe	"Farsightedness" Youth: usually do not require glasses (still have sufficient accommodative ability to focus image on retina), but may develop accommodative esotropia and amblyopia if not corrected (see *Strabismus*, OP37) 30s-40s: blurring of near vision due to decreased accommodation, may need reading glasses >50s: blurring of distance vision due to severely decreased accommodation	When symptomatic, correct with positive diopter/ convex/"plus" lenses to converge light rays Refractive eye surgery	Angle-closure glaucoma, particularly later in life as lens enlarges
Astigmatism	Light rays not refracted uniformly in all meridians due to non-spherical surface of cornea or non-spherical lens (e.g. football-shaped) **Two types** Regular – curvature uniformly different in meridians at right angles to each other Irregular – distorted cornea caused by injury, keratoconus (cone-shaped cornea), corneal scar, or severe dry eye	Affects ≈30% of population, with prevalence increasing with age Mild astigmatism unnoticeable Higher amounts of astigmatism may cause blurry vision, squinting, asthenopia, or headaches	Correct with cylindrical lens (if regular) Try contact lens (if irregular) Refractive eye surgery	
Presbyopia	Normal aging process (>40 yr) Hardening/reduced deformability of lens results in decreased accommodative ability Accommodative power is 14D at age 10, diminishes to 3.5D by age 40 Near images cannot be focused onto the retina (focus is behind the retina as in hyperopia)	If initially emmetropic, person begins to hold reading material farther away, but distance vision remains unaffected If initially myopic, person removes distance glasses to read If initially hyperopic, symptoms of presbyopia occur earlier	Correct with positive diopter/convex/"plus" lenses for reading	
Anisometropia	Difference in refractive errors between eyes			Second most common cause of amblyopia in children

Myopia

LMN
Long globe
Myopic
Negative correction/Nearsighted

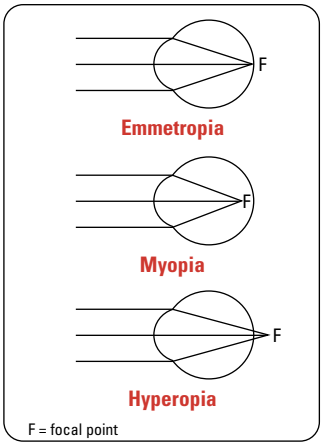

Figure 11. Emmetropia and refractive errors

Structures Responsible for Refractive Power
- Cornea (2/3)
- Lens (1/3)

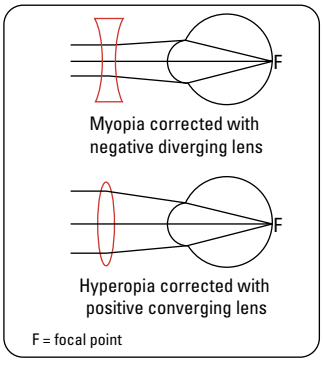

Figure 12. Correction of refractive errors

The Orbit

Globe Displacement

Table 5. Exophthalmos (Proptosis) and Enophthalmos

	Exophthalmos (Proptosis)	Enophthalmos
Definition	Anterior displacement (protrusion) of the globe Exophthalmos generally refers to an endocrine etiology or protrusion of >18 mm (as measured by a Hertel exophthalmometer) Proptosis generally refers to other etiologies (e.g. cellulitis) or protrusion of <18 mm	Posterior displacement (retraction) of the globe
Investigations	CT/MRI head/orbits, ultrasound orbits, thyroid function tests	CT/MRI orbits
Etiology	Note: rule out pseudoexophthalmos (e.g. lid retraction) Graves' disease (unilateral or bilateral, most common cause in adults) Orbital cellulitis (unilateral, most common cause in children) 1° or 2° orbital tumour Orbital/retrobulbar hemorrhage Cavernous sinus thrombosis or fistula	"Blow-out" fracture (see *Ocular Trauma*, OP41) Orbital fat atrophy Congenital abnormality Metastatic disease

Preseptal Cellulitis

Definition
- infection of soft tissue anterior to orbital septum

Etiology
- usually follows periorbital trauma or dermal infection

Clinical Features (see Table 6, OP10)

Treatment
- systemic antibiotics (suspect H. influenzae in children; S. aureus or Streptococcus in adults)
  - e.g. amoxicillin-clavulanic acid
- if severe or child <1 yr, treat as orbital cellulitis

Orbital Cellulitis

Definition
- OCULAR and MEDICAL EMERGENCY
- inflammation of orbital contents posterior to orbital septum
- common in children, elderly, and immunocompromised

Etiology
- usually secondary to sinus/facial/tooth infections or trauma, can also arise from preseptal cellulitis

Clinical Features (see Table 6, OP10)
- orbital cellulitis can be clinically indistinguishable from preseptal cellulitis
- for equivocal findings, difficult examinations, or presence of nasal discharge, perform CT or MRI orbits and sinuses

Treatment
- admit, blood cultures x2, orbital CT, IV antibiotics (ceftriaxone + vancomycin) for 1 wk
- surgical drainage of abscess with close follow-up, especially in children

Complications
- optic nerve inflammation, cavernous sinus thrombosis, meningitis, brain abscess with possible loss of vision, and death

Role of Oral Corticosteroids in Orbital Cellulitis
Am J Ophthalmol 2013;156:178-183
Purpose: To evaluate the role of oral corticosteroids as an anti-inflammatory adjunct for the treatment of orbital cellulitis.
Methods: RCT of 21 patients with acute onset (within 14 d) of orbital cellulitis with or without abscess. There were 7 patients in group 1 (standard IV antibiotics) and 14 in group 2 (adjuvant steroids).
Results: Patients in group 2 showed earlier resolution of periorbital edema, conjunctival chemosis, pain, proptosis, and EOM deficits, including decreased duration of IV antibiotics and hospital stay ($P<0.05$ for all).
Conclusion: The use of oral steroids as an adjunct to IV antibiotics for orbital cellulitis may decrease inflammatory symptoms with a low-risk of worsening infection.

Table 6. Clinical Features of Preseptal and Orbital Cellulitis

Finding	Preseptal Cellulitis	Orbital Cellulitis
Fever	May be present	Present
Lid Edema	Moderate to severe	Severe
Conjunctival Injection	Absent	Present
Chemosis	Absent or mild	Marked
Proptosis	Absent	Present
Pain on Eye Movement	Absent	Present
Ocular Mobility	Normal	Decreased
Vision	Normal	Diminished ± diplopia
RAPD	Absent	May be seen if severe
Leukocytosis	Moderate	Marked
Erythrocyte Sedimentation Rate (ESR)	Normal or elevated	Elevated
Additional Findings	Skin infection	Sinusitis, dental abscess

Lacrimal Apparatus

- tear film made up of three layers
  - outer oily layer (reduces evaporation): secreted by the meibomian glands
  - middle watery layer (forms the bulk of the tear film): constant secretion from conjunctival glands and reflex secretion by lacrimal gland with ocular irritation or emotion
  - inner mucinous layer (aids with tear adherence to cornea): secreted by conjunctival goblet cells
- tears drain from the eyes through the upper and lower lacrimal puncta ➔ superior and inferior canaliculi ➔ lacrimal sac ➔ nasolacrimal duct ➔ nasal cavity behind inferior concha (see Figure 3, OP3)

Dry Eye Syndrome (Keratoconjunctivitis Sicca)

Definition and Etiology

- aqueous-deficient
  - Sjögren syndrome (autoimmune etiology; e.g. RA, SLE)
  - non-Sjögren syndrome (idiopathic age-related disease; lacrimal gland scarring e.g. trachoma; decreased secretion e.g. contact lenses, CN VII palsy, anticholinergics, antihistamines, diuretics, β-blockers)
- evaporative (normal lacrimal function, excessive evaporation of aqueous layer)
  - meibomian gland dysfunction (posterior blepharitis)
  - vitamin A deficiency (xerophthalmia with goblet cell dysgenesis)
  - eyelid abnormalities e.g. ectropion, CN VII palsy (decreased blinking)
  - topical ocular medications with preservatives
  - contact lenses, allergic conjunctivitis
- mixed etiologies are common

Clinical Features

- dry eyes, red eyes, foreign body sensation, blurred vision, tearing, eye pain
- slit-lamp exam: decreased tear meniscus, decreased tear break-up time (normally should be >10 s), punctate staining of cornea with fluorescein

Investigations

- surface damage observed with fluorescein/Rose Bengal staining
- decreased distance in Schirmer's test

Complications

- erosions and scarring of cornea

Treatment

- medical: preservative-free artificial tears up to q1 h and ointment at bedtime (preservative toxicity becomes significant if used more than 4-6 x/d), short course of mild topical corticosteroid, omega-3 fatty acids orally (controversial), and eyelid hygiene for blepharitis
  - for moderate cases, cyclosporine ophthalmic emulsion 0.05% (Restasis®) or lifitegrast 5% (Xiidra®) can be used
- procedural: punctal occlusion (punctal plug insertion), lid taping, tarsorrhaphy (sew lids together) if severe
- treat underlying cause

Long-term use of artificial tears with preservatives should be avoided when treating dry eyes

Epiphora (Excessive Tearing)

Etiology
- emotion, pain
- environmental stressor (cold, wind, pollen, sleep deprivation)
- lid/lash malposition: ectropion, entropion, trichiasis
- inflammatory: conjunctivitis, dacryoadenitis, uveitis, keratitis, corneal foreign body
- dry eyes (reflex tearing)
- lacrimal drainage obstruction (congenital failure of canalization, aging, rhinitis, dacryocystitis)
- paradoxical gustatory lacrimation reflex ("crocodile tears")

Excessive tearing can be caused by dry eyes – if the tear quality is insufficient, "reflex tearing" may occur

Investigations
- using fluorescein dye, examine for punctal reflux by pressing on canaliculi
- Jones dye test: fluorescein placed in conjunctival cul-de-sac, and cotton applicator placed in nose to detect flow (i.e. rule out lacrimal drainage obstruction)

Treatment
- lid repair for ectropion or entropion
- eyelash removal for trichiasis
- punctal irrigation (dilation and irrigation)
- nasolacrimal duct probing (infants)
- tube placement: temporary (Crawford) or permanent (Jones)
- surgical: dacryocystorhinostomy – forming a new connection between the lacrimal sac and the nasal cavity

Dacryocystitis

Etiology
- acute or chronic infection of the lacrimal sac
- most commonly due to obstruction of the nasolacrimal duct
- commonly associated with *S. aureus*, *S. pneumoniae*, *Pseudomonas* species

Clinical Features
- pain, swelling, and redness over lacrimal sac at medial canthus
- epiphora, crusting, ± fever
- digital pressure on the lacrimal sac may extrude pus through the punctum
- in the chronic form, epiphora may be the only symptom

Treatment
- warm compresses, nasal decongestants, systemic and topical antibiotics (cephalexin if afebrile; cefazolin if febrile)
- I&D; if chronic, obtain cultures by aspiration
- once infection resolves, consider dacryocystorhinostomy

Dacryoadenitis

Etiology
- most commonly seen in children and young adults
- inflammation of the lacrimal gland (outer third of upper eyelid)
- acute causes: *S. aureus*, mumps, EBV, herpes zoster, *N. gonorrhoeae*
- chronic causes (often bilateral): lymphoma, leukemia, sarcoidosis, tuberculosis, TED

Clinical Features
- pain, swelling, tearing, discharge, and redness of the outer region of the upper eyelid
- chronic form is more common and may present as painless enlargement of the lacrimal gland

Treatment
- supportive: warm compresses, oral NSAIDs
- systemic antibiotics if bacterial cause
- if chronic, treat underlying disorder

Lids and Lashes

Lid Swelling

Etiology
- commonly due to allergy, with blepharochalasis (thinning of skin due to recurrent edema)
- dependent edema on awakening (e.g. CHF, renal or hepatic failure)
- orbital venous congestion due to mass or cavernous sinus fistula
- dermatochalasis (loose skin due to aging or heredity)
- lid cellulitis, TED, trauma, and chemosis

Ptosis

Definition
- drooping of upper eyelid

Etiology
- aponeurotic: disinsertion or dehiscence of levator aponeurosis (most common)
  - associated with advancing age, trauma, surgery, pregnancy, chronic lid swelling
- mechanical
  - incomplete opening of eyelid due to mass or scarring
- neuromuscular
  - myasthenia gravis (neuromuscular palsy), myotonic dystrophy
  - CN III palsy
  - Horner's syndrome (see *Constricted Pupil (Miosis): Horner's Syndrome*, OP31)
- congenital
- pseudoptosis (e.g. dermatochalasis, enophthalmos, contralateral exophthalmos)
- drugs (e.g. high dose opioids, heroin abuse, pregabalin)

Treatment
- surgery (e.g. blepharoplasty, levator resection, Müller's muscle resection, and frontalis sling)

Trichiasis

Definition
- eyelashes turned inwards

Etiology
- may result from entropion, involutional age change, chronic inflammatory lid diseases (e.g. blepharitis), trauma, burns

Clinical Features
- patient complains of red eye, foreign body sensation, significant discomfort, tearing
- may cause corneal abrasions with secondary ulceration and scarring

Treatment
- topical lubrication, repeat eyelash epilation, electrolysis, and cryotherapy

Entropion

Definition
- lid margin folds inward towards globe

Etiology
- involutional (aging)
- cicatricial (herpes zoster, surgery, trauma, burns)
- orbicularis oculi muscle spasm
- congenital

Testing for Entropion
Forced lid closure: Ask patient to tighten lid then open. In entropion, lid rolls inwards

Clinical Features
- tearing, foreign body sensation, and red eye
- most commonly affects lower lid
- may cause corneal abrasions with secondary corneal scarring

Treatment
- lubricants, evert lid with tape, and surgery

Ectropion

Definition
- lid margin folds outward from globe

Etiology
- involutional (aging)
- paralytic (CN VII palsy)
- cicatricial (burns, trauma, and surgery)
- mechanical (lid edema, tumour, and herniated fat)
- congenital

Testing for Ectropion
Snapback test: Pull eyelid inferiorly. In ectropion, lid remains away from globe

Clinical Features
- tearing and possibly exposure keratitis

Treatment
- topical lubrication, eyelid taping overnight, and surgery

Hordeolum (Stye)

Definition
- acute inflammation of eyelid gland: either meibomian glands (internal lid), glands of Zeis (modified sweat gland), or Moll glands (modified sebaceous gland in external lid)

Hordeolum vs. Chalazion
Hordeola are due to an infectious etiology, whereas chalazions are granulomatous inflammation

Clinical Features
- infectious agent is usually *S. aureus*
- painful, red swelling of lid

Treatment
- warm compresses, lid care, gentle massage
- topical antibiotics are typically ineffective
- usually resolves within 2 wk, but may require I&D

Chalazion

Definition
- chronic granulomatous inflammation of a meibomian gland often preceded by an internal hordeolum

Clinical Features
- acute inflammatory signs are usually absent
- differential diagnosis: basal cell carcinoma, sebaceous cell carcinoma, meibomian gland carcinoma

Treatment
- warm compresses
- if no improvement after 1 mo, consider incision and curettage
- chronic recurrent lesion must be biopsied to rule out malignancy

Blepharitis

Definition
- inflammation of lid margins

Etiology
- anterior blepharitis
  - *Staphylococcus* (*S. aureus*): ulcerative, dry scales
  - seborrheic: no ulcers, greasy scales
- posterior blepharitis
  - meibomian gland dysfunction

Clinical Features
- itching, tearing, foreign body sensation
- thickened, red lid margins, crusting, discharge with pressure on lids ("toothpaste sign")

Complications
- recurrent hordeola
- conjunctivitis
- keratitis (from poor tear film)
- corneal ulceration and neovascularization

Treatment
- warm compresses, lid massages, and lid washing using commercially available eyelid scrub solution
- topical or systemic antibiotics (doxycycline) as needed
- if severe, ophthalmologist may prescribe a short course of topical corticosteroids, omega-3 fatty acids

Xanthelasma

Definition
- eyelid xanthoma (lipid deposits in dermis of lids)

Clinical Features and Associations
- appear as pale, slightly elevated yellowish plaques or streaks
- most commonly on the medial upper lids, often bilateral
- associated with hyperlipidemia (~50% of patients)
- common in the elderly, more concerning in young people

Treatment
- excision for cosmesis only, commonly recurs

Conjunctiva

- thin, vascular mucous membrane
- bulbar conjunctiva: lines sclera to limbus (junction between cornea and sclera)
- palpebral (tarsal) conjunctiva: lines inner surface of eyelid

Pinguecula

Definition
- yellow-white subepithelial deposit of hyaline and elastic tissue adjacent to the nasal or temporal limbus, sparing the cornea

Clinical Features
- associated with sun and wind exposure, aging
- benign, sometimes enlarges slowly
- may be irritating due to abnormal tear film formation over the deposits

Treatment
- surgery for cosmesis only
- irritative symptoms may be treated with lubricating drops

Pterygium

Definition
- fibrovascular, triangular, wing-like encroachment of epithelial tissue onto the cornea

Clinical Features
- may induce astigmatism, decrease vision

Treatment
- excision for chronic inflammation, threat to visual axis, and/or cosmesis
- irritative symptoms may be treated with lubricating drops
- one-third recur after bare excision, lower recurrence with conjunctival autograft (~5%)

Subconjunctival Hemorrhage

- blood beneath the conjunctiva, otherwise asymptomatic
- idiopathic or associated with trauma, Valsalva maneuver, bleeding disorders, HTN, anticoagulation
- give reassurance if no other ocular findings, resolves spontaneously in 2-3 wk
- 360° involvement should be highly suspicious for globe rupture if trauma history
- if recurrent, consider medical/hematologic workup, especially if non-traumatic in nature

Conjunctivitis

Etiology
- infectious
  - bacterial, viral, chlamydial, gonococcal, fungal, and parasitic
- non-infectious
  - allergic, atopic, seasonal, GPC (contact lens wearers)
  - toxic: irritants, dust, smoke, irradiation
  - secondary to another disorder: dacryocystitis, dacryoadenitis, cellulitis, and systemic inflammatory disease

Clinical Features
- red eye (conjunctival injection), chemosis
- itching, foreign body sensation, tearing, discharge, crusting of lashes in the morning, and lid edema
- ± preauricular and/or submandibular nodes
- follicles: pale lymphoid elevations of the conjunctiva, overlain by vessels
- papillae: fibrovascular elevations of the conjunctiva with central network of finely branching vessels (cobblestone appearance)

ALLERGIC CONJUNCTIVITIS
- associated with rhinitis, asthma, dermatitis, and hay fever
- ocular pruritus, small papillae, chemosis, redness, thickened and erythematous lids
- seasonal (pollen, grasses, plant allergens)

Treatment
- allergen avoidance, cool compresses, non-preserved artificial tears, topical or oral antihistamine, topical mast cell stabilizer (e.g. cromolyn, ketotifen, olopatadine), and topical corticosteroids

ATOPIC CONJUNCTIVITIS
- onset late adolescence and early adulthood with peak between 30-50 yr
- intense ocular pruritus (perennially), tearing, burning, clear mucus discharge, redness, blurry vision, photophobia, and foreign body sensation
- thickened and intermittent swelling of the eyelids, conjunctival chemosis, conjunctival hyperemia, and tarsal papillary hypertrophy
- severe cases lead to sub-epithelial fibrosis, fornix foreshortening, and corneal neovascularization

Treatment
- calcineurin inhibitor ointment (e.g. tacrolimus and pimecrolimus), topical cyclosporine drops, and topical corticosteroid drops

GIANT PAPILLARY CONJUNCTIVITIS (GPC)
- immune reaction to mucus debris on lenses in contact lens wearers
- large papillae form on superior palpebral conjunctiva

Treatment
- clean, change, or discontinue use of contact lens, and topical corticosteroids

VERNAL CONJUNCTIVITIS
- large papillae (cobblestones) form on superior palpebral conjunctiva with corneal shield ulcers, limbal follicles, and keratitis
- seasonal (warm weather)
- occurs in children, lasts for 5-10 yr then resolves

Treatment
- non-preserved artificial tears, consider topical steroid, topical cyclosporine (by ophthalmologist)

VIRAL CONJUNCTIVITIS (PINK EYE)
- presents with pain and swelling
- serous discharge, lid edema, follicles, and pseudomembranes
- subepithelial corneal infiltrates
- preauricular node often palpable and tender
- initially unilateral, often progresses to the other eye within a few days
- mainly due to adenovirus – highly contagious for up to 12 d

Treatment
- usually self-limiting (7-12 d)
- cool compresses, topical lubrication
- proper hygiene is important to prevent transmission

Types of Discharge
- Allergic: mucoid
- Viral: watery
- Bacterial: purulent
- Chlamydial: mucopurulent

Follicles are usually seen in viral and chlamydial conjunctivitis
Papillae are usually seen in allergic and bacterial conjunctivitis

Antibiotics vs. Placebo for Acute Bacterial Conjunctivitis
Cochrane DB Syst Rev 2012;9:CD001211
Purpose: To assess the benefits and harms of antibiotic therapy in the management of acute bacterial conjunctivitis.
Criteria: RCTs with any form of antibiotic treatment compared with placebo including topical, systemic, or combined (e.g. antibiotics and steroids) antibiotic treatments.
Results: 11 RCTs, 3673 participants. Topical antibiotics improve early (2-5 d) clinical and microbiological remission rates (RR 1.36, 95% CI 1.15-1.61; RR 1.55; 95% CI 1.37-1.76) and benefit clinical remission and microbiological cure rates at a late time point (6-10 d) (RR 1.21, 95% CI 1.10-1.33; RR 1.37, 95% CI 1.24-1.52). By 6-10 d 41% of cases had resolved in the placebo group. No serious outcomes were reported in any group.
Conclusion: The use of antibiotic eye drops is associated with modestly improved rates of clinical and microbiological remission in comparison to placebo. Antibiotic eye drops should therefore be considered in order to speed the resolution of symptoms and infection although acute bacterial conjunctivitis is frequently self-limiting.

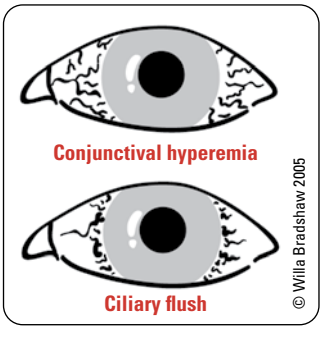

Figure 13. Conjunctival hyperemia vs. ciliary flush

BACTERIAL CONJUNCTIVITIS
- purulent discharge, lid swelling, papillae, conjunctival injection, and chemosis
- common agents include *S. aureus, S. pneumoniae, H. influenzae*, and *M. catarrhalis*
- in neonates or if sexually active must consider *N. gonorrhoeae* (can cause hyperpurulent conjunctivitis, a serious infection that may rapidly perforate cornea)
- *C. trachomatis* is the most common cause in neonates

- Enlarged lymph nodes suggest infectious etiology, especially viral or chlamydial conjunctivitis
- Temporal conjunctival lymphatics drain to preauricular nodes, and nasal to submandibular nodes

Treatment
- topical broad-spectrum antibiotic, systemic antibiotics if indicated (especially in neonates and children)
- usually a self-limited course of 10-14 d if no treatment, 1-3 d with treatment

GONOCOCCAL AND CHLAMYDIAL CONJUNCTIVITIS
- caused by *N. gonorrhoeae* and *C. trachomatis*, respectively
- affects sexually active individuals, neonates (ophthalmia neonatorum) in first 5 d of life when caused by gonorrhea (shorter incubation period) and 3-14 d of life when caused by chlamydia (longer incubation period)
- newborn prophylaxis with erythromycin 0.5% ointment
- documented or suspected cases of gonococcal conjunctivitis should be evaluated by an ophthalmologist for intensive IV and topical treatment
- chlamydia causes trachoma and inclusion conjunctivitis (different serotypes)

TRACHOMA
- leading infectious cause of blindness in the world
- severe keratoconjunctivitis leads to corneal abrasion, ulceration, and scarring
- initially, follicles on superior palpebral conjunctiva and later palpebral scarring (Arlt's line)

Treatment
- oral azithromycin and topical tetracycline
- IV ceftriaxone often given in the emergency department

INCLUSION CONJUNCTIVITIS
- chronic conjunctivitis with follicles and subepithelial infiltrates

Treatment
- oral azithromycin, tetracycline, doxycycline

Sclera

- white fibrous outer protective coat of the eye, composed of irregularly distributed collagen bundles
- continuous with the cornea anteriorly and the dura of the optic nerve posteriorly
- episclera is a thin layer of vascularized tissue between the sclera and conjunctiva

Episcleritis

Definition
- immunologically mediated inflammation of episclera
- 1/3 bilateral; simple (80%) or nodular (20%)
- more frequent in women than men (3:1)

Etiology
- mostly idiopathic
- associated with collagen vascular diseases, infections (herpes zoster, herpes simplex, and syphilis), inflammatory bowel disease, rosacea, and atopy

Clinical Features
- may have discomfort and pain associated with red eye (often interpalpebral)
- sectoral or diffuse injection of radially-directed vessels, chemosis, small mobile nodules
- blanches with topical phenylephrine (constricts superficial vessels)

To differentiate between episcleritis and scleritis, place a drop of phenylephrine 2.5% (Mydfrin®; AK-Dilate®) in the affected eye. Re-examine the vascular pattern 10-15 min later; in episcleritis the episcleral vessels should blanch with phenylephrine

Treatment
- generally self-limited, recurrent in 2/3 of cases (may need systemic work-up)
- topical steroid
- oral NSAIDs

Scleritis

- usually unilateral
- can be classified as anterior or posterior
  - anterior scleritis can be further classified as diffuse, nodular, necrotizing with inflammation, or necrotizing without inflammation (scleromalacia perforans)
  - posterior scleritis can be further classified as diffuse or nodular
- anterior scleritis: pain radiating to face, may cause scleral thinning, in some cases necrotizing
- posterior scleritis: rapidly progressive blindness, may cause exudative RD
- more common in women and elderly

Etiology
- collagen vascular disease, e.g. SLE, RA, GPA, ankylosing spondylitis
- granulomatous, e.g. tuberculosis, sarcoidosis, syphilis
- metabolic, e.g. gout, thyrotoxicosis
- infectious, e.g. *S. aureus, S. pneumoniae, P. aeruginosa*, herpes zoster
- chemical or physical agents, e.g. thermal, alkali, or acid burns
- idiopathic

Clinical Features
- severe "deep" or "boring" pain, photophobia, red eye, decreased vision
- pain is the best indicator of disease progression
- inflammation of scleral, episcleral, and conjunctival vessels
- may have anterior chamber cells and flare, corneal infiltrate, scleral thinning, scleral edema
- sclera may have a purple or "violaceous" hue (best seen in natural light), due to thinning of scleral fibres exposing the bluish-coloured uvea
- failure to blanch with topical phenylephrine

Scleromalacia Perforans
- Asymptomatic anterior necrotizing scleritis without inflammation
- Strongly associated with RA
- May result in scleral thinning
- Traumatic perforation can easily occur – examine eye very gently

Treatment
- vision threatening – urgent referral to ophthalmology
- life threatening – indicator of poor systemic disease control with an increased 5 yr mortality rate (not from scleritis) without treatment of underlying untreated or unrecognized autoimmune condition
- systemic NSAIDs, systemic steroid, and systemic immunomodulation
- treat underlying etiology

Cornea

- function
  - transmission of light
  - refraction of light (2/3 of total refractive power of eye)
  - barrier against infection, foreign bodies
- transparency due to avascularity, uniform collagen structure, and deturgescence (relative dehydration)
- 5 layers (anterior to posterior): epithelium, Bowman's layer, stroma, Descemet's membrane, and the endothelium (dehydrates the cornea; dysfunction leads to corneal edema). Some have argued the existence of a 6th layer, "Dua's layer", although it is debated if this is a truly unique and additional layer.
- extensive sensory fibre network (V1 distribution); therefore, abrasions are very painful

Learn the Layers of the Cornea
ABCDE
Anterior epithelium
Bowman's Membrane
Corneal Stroma
Descemet's Membrane
Endothelium

Foreign Body

Definition
- foreign material in or on surface of cornea

Clinical Features
- patients may note pain, tearing, photophobia, foreign body sensation, and red eye
- signs include foreign body, conjunctival injection, epithelial defect that stains with fluorescein, corneal edema, and anterior chamber cells/flare
- may have associated rust ring if metallic

Foreign body behind lid may cause multiple vertical corneal epithelial abrasions due to blinking

Complications
- abrasion, infection, ulcer, scarring, rust ring, secondary iritis

Topical analgesics should only be used to facilitate examination. They should NEVER be used as treatment for any ocular problem

Treatment
- remove under magnification using local anesthetic and sterile needle or refer to ophthalmology for removal under magnification (depending on depth and location)
- treat as per corneal abrasion

Corneal Abrasion

Definition
- epithelial defect usually due to trauma (e.g. fingernails, paper, twigs), contact lens (Figure 14)

Clinical Features (Table 7, OP19)
- pain, redness, tearing, photophobia, foreign body sensation
- de-epithelialized area stains with fluorescein dye
- pain relieved with topical anesthetic (DO NOT use for treatment – risk of corneal melt or infection)

Complications
- infection, ulceration, recurrent erosion, secondary iritis

Treatment
- topical antibiotic (drops or ointment), abrasion from organic material should be covered against Pseudomonas
- consider topical NSAIDs (caution due to risk of corneal melt with prolonged use), cycloplegic (relieves pain and photophobia by paralyzing ciliary muscle), patch (do not patch contact lens wearers as it can precipitate infection)
- most abrasions clear spontaneously within 24-48 h

Corneal abrasions from organic matter (e.g. twig, fingernail, etc.) have higher recurrence, even years later

Patching for Corneal Abrasion
Cochrane DB Syst Rev 2016;7:CD004764
Purpose: To assess the effects of patching for corneal abrasion on healing and pain relief.
Methods: Systematic review and meta-analysis of RCTs/Quasi-RCTs that compared patching the eye with no patching to treat simple corneal abrasions.
Results: 12 RCTs/Quasi-RCTs identified, n=1080. At 24 h: people receiving patch were less likely to have a healed abrasion (RR 0.89, 95% CI 0.79-1.00). At 48 h: similar effect for both groups (RR 0.97, 95% CI 0.91-1.02). At 72 h: similar effect for both groups (RR 1.01, 95% CI 0.97-1.05).
Conclusions: Certainty of evidence is moderate to low; more research is needed with better quality trials to examine effectiveness of patching for large abrasions. Participants with patch were more likely to receive additional adjuvant treatment and took slightly longer to heal, but the difference was small and possibly clinically insignificant.

Recurrent Erosions

Definition
- recurrent episodes of pain, photophobia, foreign body sensation with a spontaneous corneal epithelial defect
- usually occurs upon awakening
- associated with improper adherence of epithelial cells to the underlying basement membrane

Etiology
- previous traumatic corneal abrasion
- corneal dystrophy
- idiopathic

Treatment
- same as corneal abrasion until re-epithelialization occurs
- topical hypertonic saline ointment at bedtime for 6-12 mo, topical lubrication
- bandage contact lens, anterior stromal puncture, superficial keratectomy with diamond burr polishing, or phototherapeutic keratectomy for chronic recurrences

Corneal Ulcer

Etiology
- local necrosis of corneal tissue due to infection
  - infection is usually bacterial; rarely viral, fungal, or protozoan (Acanthamoeba)
- secondary to corneal exposure, abrasion, foreign body, or contact lens use (50% of ulcers)
- also associated with conjunctivitis, blepharitis, keratitis, vitamin A deficiency

Clinical Features
- pain, photophobia, tearing, foreign body sensation, decreased VA (if central ulcer)
- corneal opacity that necroses and forms an excavated ulcer with infiltrative base
- overlying corneal epithelial defect that stains with fluorescein
- may develop corneal edema, conjunctival injection, anterior chamber cells/flare, hypopyon, corneal hypoesthesia (in viral keratitis)
- bacterial ulcers may have purulent discharge, viral ulcers may have watery discharge

Complications
- decreased vision, corneal perforation, iritis, endophthalmitis

Investigations
- Seidel test: fluorescein drop on the cornea under cobalt blue filter is used to detect leaking penetrating lesions; any aqueous leakage will dilute the green stain at site of wound

Treatment
- urgent referral to ophthalmology
- culture prior to treatment
- topical antibiotics every hour
- must treat vigorously to avoid complications

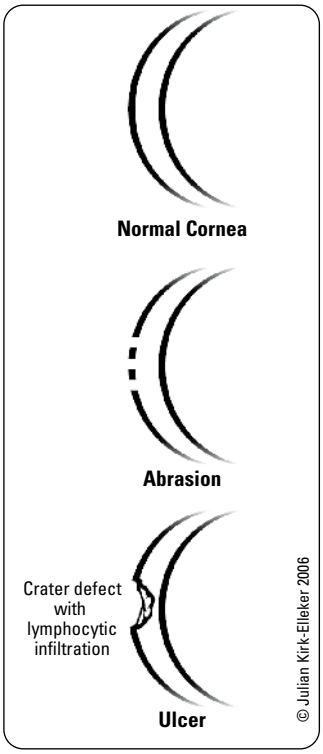

Figure 14. Corneal abrasion vs. ulcer

Table 7. Corneal Abrasion vs. Corneal Ulcer

	Abrasion	Ulcer
Time Course	Acute (instantaneous)	Subacute (days)
History of Trauma	Commonly	Rare
Cornea	Clear	White, necrotic area
Iris Detail	Clear	Obscured
Corneal Thickness	Normal	May have crater defect/thinning
Depth of Lesion	Limited to epithelium	Extension into stroma

Abrasion vs. Ulcer on Slit-Lamp
An abrasion appears clear while an ulcer is more opaque

Herpes Simplex Keratitis

- usually HSV type 1 (90% of population are carriers) but also can be type 2
- may be triggered by stress, fever, sun exposure, and/or immunosuppression

Clinical Features
- pain, tearing, foreign body sensation, red eye, decreased vision, and/or eyelid edema
- corneal hypoesthesia
- classic form of HSV infectious epithelial keratitis is a dendritic (thin and branching) lesion with terminal end bulbs in epithelium that stains with fluorescein
- HSV may cause other forms of infectious epithelial keratitis, as well as stromal keratitis (which may be infectious or immune-mediated) and endotheliitis (presumably immune-mediated but possible role of live virus)

Complications
- corneal scarring (can lead to loss of vision) and hypoesthesia
- chronic interstitial keratitis due to penetration of virus into stroma
- secondary iritis, secondary glaucoma

Treatment
- topical antiviral such as trifluridine, or systemic antiviral such as acyclovir
- debridement of dendrite
- no steroids initially for epithelial disease – may exacerbate condition
- ophthalmologist must exercise caution if adding topical steroids for stromal keratitis, endotheliitis or iritis, and patients covered with antiviral prophylaxis

Steroid treatment for ocular disorders should only be prescribed and supervised by an ophthalmologist, as they can impair corneal healing, exacerbate herpetic keratitis, and elevate IOP

Herpes Zoster Ophthalmicus

Definition
- dermatitis in the dermatomal distribution of CN V1 that is typically unilateral and respects the midline
- Hutchinson's sign: if tip of nose is involved (nasociliary branch of V1) then globe will be involved in ~75% of cases
- if no nasal involvement, eye is involved in 1/3 of patients

Clinical Features
- pain, tearing, photophobia, and red eye
- corneal edema, pseudodendrite, and SPK
- corneal hypoesthesia

Complications
- keratitis, ulceration, perforation, and scarring
- secondary iritis, secondary glaucoma, cataract
- muscle palsies (rare) due to CNS involvement
- occasionally severe post-herpetic neuralgia

Treatment
- oral antiviral (acyclovir, valacyclovir, or famciclovir) immediately
- topical steroids, cycloplegia as indicated for immune-mediated keratitis, iritis
- erythromycin ointment if conjunctival involvement

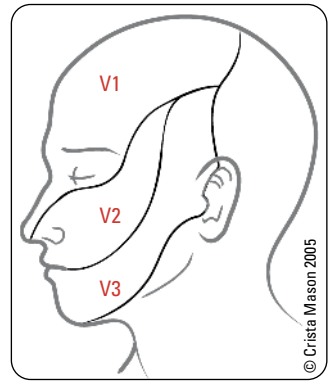

Figure 15. Trigeminal distribution

Keratoconus

Definition
- bilateral (usually asymmetric) thinning and bulging (ectasia) of the cornea resulting in a conical shape
- usually sporadic but can be associated with Down syndrome, atopy, contact lens use, and vigorous eye rubbing
- associated with breaks in Descemet's membrane and Bowman's layer
- results in decreased vision from irregular astigmatism, scarring, and stromal edema

To detect keratoconus, look for bulging of the lower eyelid when the patient looks downward (Munson's sign)

Treatment
- attempt correction with spectacles and/or rigid gas permeable or scleral contact lens
- corneal collagen cross-linking treatment to halt disease progression
- intrastromal corneal ring segments can help flatten the corneal cone
- penetrating keratoplasty or deep anterior lamellar keratoplasty (partial-thickness corneal transplant) as last resort

Arcus Senilis

- hazy white ring in peripheral cornea, <2 mm wide, clearly separated from limbus
- common, bilateral, benign corneal degeneration due to lipid deposition, part of the aging process
- may be associated with hypercholesterolemia if age <40 yr, check lipid profile
- no associated visual symptoms, complications, or treatment necessary

Kayser-Fleischer Ring

- brown-yellow-green pigmented ring in peripheral cornea, starting inferiorly
- due to deposition of copper pigment in Descemet's membrane
- associated with Wilson's disease
- no associated symptoms or complications of ring
- treat underlying disease

The Uveal Tract

- uveal tract (from anterior to posterior) = iris, ciliary body, choroid
- vascularized, pigmented middle layer of the eye, between the sclera and the retina

Uveitis

- uveal inflammation which may involve one, two, or all three parts of the tract
- idiopathic or associated with autoimmune, infectious, granulomatous, and malignant causes
- should be managed by an optometrist or ophthalmologist
- anatomically classified as anterior uveitis, intermediate uveitis, posterior uveitis, or panuveitis based on primary site of inflammation

Table 8. Anatomic Classification of Uveitis

	Anterior Uveitis (Iritis)	Intermediate Uveitis	Posterior Uveitis
Location	Inflammation of iris, usually accompanied by cyclitis (inflammation of ciliary body), both = iridocyclitis Usually unilateral	The vitreous is the major site of the inflammation	Inflammation of the choroid (choroiditis), retina (retinitis), or both (chorioretinitis)
Etiology	Usually idiopathic Connective tissue diseases: HLA-B27: reactive arthritis, ankylosing spondylitis, psoriatic arthritis, inflammatory bowel disease Non-HLA-B27: juvenile idiopathic arthritis Infectious: syphilis, Lyme disease, toxoplasmosis, TB, HSV, herpes zoster Other: sarcoidosis, trauma, large abrasion, and postocular surgery	Mostly idiopathic, secondary causes include sarcoidosis, Lyme disease, and multiple sclerosis	Bacterial: syphilis, tuberculosis Viral: herpes simplex/zoster virus, CMV in AIDS Fungal: histoplasmosis, candidiasis Parasitic: toxoplasmosis (most common cause), toxocara Immunosuppression may predispose to any of the above infections Autoimmune: Behçet's disease (triad of oral ulcers, genital ulcers, and posterior uveitis) Malignancies (masquerade syndrome): metastatic lesions, malignant melanoma, lymphoma
Clinical Features	Photophobia (due to reactive spasm of inflamed iris muscle), ocular pain, tenderness of the globe, brow ache (ciliary muscle spasm), decreased VA, lacrimation Ciliary flush (perilimbal conjunctival injection), miosis (spasm of sphincter muscle) Anterior chamber "cells" (WBC in anterior chamber due to anterior segment inflammation) and "flare" (protein in anterior chamber secondary to inflammation), hypopyon (collection of neutrophilic cells/exudate inferiorly in the anterior chamber) Occasionally keratic precipitates (clumps of cells on corneal endothelium) Iritis typically reduces IOP because ciliary body inflammation causes decreased aqueous production; however, severe iritis or iritis from herpes simplex and zoster may cause inflammatory glaucoma (trabeculitis)	Insidious onset of blurred vision, accompanied by vitreous floaters Initial symptoms are usually unilateral but inflammatory changes are usually bilateral and asymmetric Associated with anterior uveitis, most severe cases of secondary intermediate uveitis Vitreous cells, condensations, and snowballs (vitreous aggregates of inflammatory cells) Posterior segment 'snowbank' = grey-white fibrovascular plaque at the pars plana	Painless Often no conjunctival or scleral injection present Decreased VA Floaters (debris and inflammatory cells) Vitreous cells and opacities Hypopyon formation

Table 8. Anatomic Classification of Uveitis

	Anterior Uveitis (Iritis)	Intermediate Uveitis	Posterior Uveitis
Complications	Inflammatory glaucoma Posterior synechiae Adhesions of posterior iris to anterior lens capsule Indicated by an irregularly shaped pupil If occurs 360°, can lead to angle closure glaucoma Peripheral anterior synechiae (rare) Adhesions of iris to cornea Can lead to secondary angle closure glaucoma Cataracts (usually posterior subcapsular) Band keratopathy - superficial corneal calcification (seen in chronic iritis) Macular edema with chronic iritis	Cystoid macular edema (30% of cases), cataract, and glaucoma	Macular edema Vitritis Neovascularization Visual field loss/scotoma
Treatment	Mydriatics: dilate pupil to prevent formation of posterior synechiae and to decrease pain from ciliary spasm Steroids: topical, sub-tenon, or systemic Systemic analgesia If recurrent episodes, medical workup may be indicated to rule out secondary causes	Systemic or sub-tenon/intravitreal steroids and immunosuppressive agents Vitrectomy, cryotherapy, or laser photocoagulation to the "snowbank"	Steroids: sub-tenon, intravitreal, or systemic if indicated (e.g. threat of vision loss) Vitreous biopsy if suspected masquerade/malignancy

Lens

- consists of an outer capsule surrounding a soft cortex and a firm inner nucleus

Cataracts

Definition
- any opacity of the lens, regardless of etiology
- most common cause of reversible blindness worldwide
- types: nuclear sclerosis, cortical, and posterior subcapsular

Etiology
- acquired
  - age-related (over 90% of all cataracts)
  - cataract associated with systemic disease (may have juvenile onset)
    - DM
    - metabolic disorders (e.g. Wilson's disease, galactosemia, or homocystinuria)
    - hypocalcemia
  - traumatic (may be rosette-shaped)
  - intraocular inflammation (e.g. uveitis)
  - toxic (steroids, phenothiazines)
  - radiation
- congenital
  - high myopia
  - present with altered red reflex or leukocoria
  - treat promptly to prevent amblyopia

Clinical Features
- gradual, painless, progressive decrease in VA
- glare, dimness, halos around lights at night, monocular diplopia
- "second sight" phenomenon: patient is more myopic than previously noted, due to increased refractive power of the lens (in nuclear sclerosis only)
  - patient may read without previously needed reading glasses
- diagnosis by slit-lamp exam
- may impair view of retina during fundoscopy

Treatment
- medical: no role for medical management
- surgical: definitive treatment
  - indications for surgery
    - to improve visual function in patients whose vision loss leads to functional impairment
    - to aid management of other ocular disease (e.g. cataract that prevents adequate retinal exam or laser treatment of DR)
    - congenital or traumatic cataracts
  - phacoemulsification (phaco = lens)
    - most commonly used surgical technique
    - postoperative complications: RD, endophthalmitis, dislocated IOL, macular edema, glaucoma, posterior capsular opacification

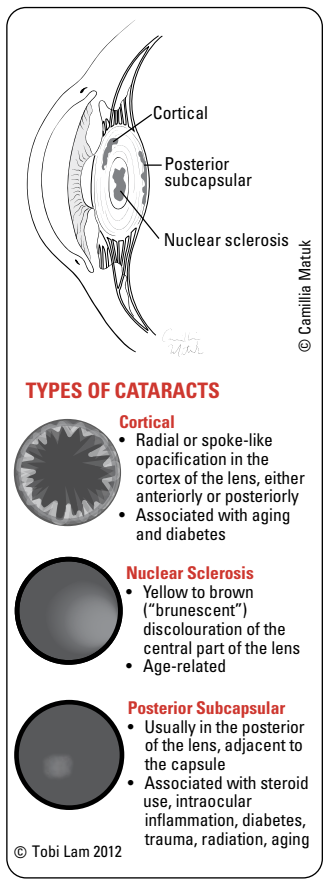

Figure 16. Types of cataracts

Dislocated Lens (Ectopia Lentis)

Etiology
- associated with Marfan Syndrome, Ehlers-Danlos type VI, homocystinuria, syphilis, lens coloboma (congenital cleft due to failure of ocular adnexa to complete growth)
- traumatic

Clinical Features
- decreased VA
- may get monocular diplopia
- iridodonesis (quivering of iris with movement)
- phacodonesis (observed movement of the lens)
- direct ophthalmoscopy may elicit abnormal red reflex

Complications
- cataract, glaucoma, and uveitis

Treatment
- surgical lens replacement

Vitreous

- clear gel (99% water plus collagen fibrils, glycosaminoglycans, and hyaluronic acid) that fills the posterior segment of eye
- normally adherent to optic disc, vitreous base (pars plana/ora serrata), and along major retinal blood vessels

Posterior Vitreous Detachment

Etiology
- central vitreous commonly shrinks and liquefies with age (syneresis)
- during syneresis, vitreous fibrils condense causing vitreous floaters
- liquid vitreous moves between posterior vitreous gel and retina
- vitreous is peeled away and separates from the internal limiting membrane of the neurosensory retina posterior to the vitreous base

Clinical Features
- floaters, flashes of light

Complications
- traction at sites of firm adhesion may result in retinal tear with or without subsequent rhegmatogenous retinal detachment
- retinal tears/detachment may cause vitreous hemorrhage if bridging retinal blood vessel is torn
- complications more common in high myopes and following ocular trauma (blunt or perforating)

Treatment
- acute onset of PVD requires a dilated fundus exam to rule out retinal tears/detachment
- no specific treatment available for floaters/flashes of light

Weiss Ring: formed by glial tissue around the optic disc that remains attached to the detached posterior vitreous

Floaters: "bugs", "cobwebs", or "spots" of vitreous condensation that move with eye position

Although most floaters are benign, new or markedly increased floaters or flashes of light require a dilated fundus exam to rule out retinal tears/detachment

Vitreous Hemorrhage

Definition
- bleeding into the vitreous cavity

Etiology
- PDR
- retinal tear/detachment
- PVD
- retinal vein occlusion
- trauma

Clinical Features
- sudden loss of VA
- may be preceded by "shower" of many floaters and/or flashes of light
- ophthalmoscopy: no red reflex if large hemorrhage, retina not visible due to blood in vitreous

Treatment
- ultrasound (B-scan) to rule out RD
- expectant: in non-urgent cases (e.g. no RD), blood usually resorbs in 3-6 mo
- surgical: vitrectomy ± RD repair ± retinal endolaser for bleeding sites/retinal tears

Any time a vitreous or retinal hemorrhage is seen in a child, must consider child abuse

Endophthalmitis and Vitritis

Definition
- intraocular infection: acute, subacute, or chronic

Etiology
- most commonly as postoperative complication; risk following cataract surgery is <0.1%
- also due to penetrating injury to eye (risk is 3-7%), endogenous spread, and intravitreal injections
- etiology usually bacterial, may be fungal

Remember to inquire about tetanus status in post-traumatic endophthalmitis

Clinical Features
- painful, red eye, photophobia, discharge
- severely reduced VA, lid edema, proptosis, corneal edema, anterior chamber cells/flare, hypopyon, reduced red reflex
- may have signs of a ruptured globe (severe subconjunctival hemorrhage, chemosis, hyphema, decreased IOP, etc.)

Treatment (see *Ocular Trauma*, OP41)
- **OCULAR EMERGENCY**: presenting vision indicates prognosis
- LP or worse: admission, immediate vitrectomy, and intravitreal antibiotics to prevent loss of vision
- HM or better: vitreous tap for culture and intravitreal antibiotics
- topical fortified antibiotics

Retina

- composed of two parts (Figure 2, OP2)
  - neurosensory retina: comprises 9 of the 10 retinal layers, including photoreceptors and ganglion cell layer
  - RPE layer: external to neurosensory retina
- macula: rich in cones (for colour vision), most sensitive area of retina
- fovea: centre of macula, responsible for detail, fine vision, lacks retinal vessels
- optic disc: collection of retinal nerve fibre layers forming optic nerve (CN II)
- ora serrata: irregularly-shaped, anterior margin of the retina (cannot be visualized with direct ophthalmoscope, but possible with indirect ophthalmoscope/scleral depression)

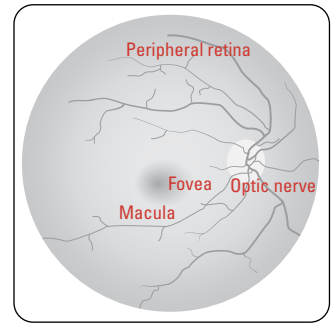

Figure 17. Retina

Central/Branch Retinal Artery Occlusion

Etiology
- occlusion of blood flow from the following causes results in loss of vision due to oxygen starvation of the retinal tissues and eventual cell death
  - emboli from carotid arteries or heart (e.g. arrhythmia, endocarditis, valvular disease)
  - thrombus
  - GCA/temporal arteritis

Hallmark of CRAO
"Cherry-red spot" located at centre of macula (visualization of unaffected highly vascular choroid through the thin fovea)

Clinical Features
- sudden, painless (except in GCA), severe monocular loss of vision
- RAPD in CRAO or large BRAO
- patient may have experienced transient episodes in the past (amaurosis fugax)
- fundoscopy
  - "cherry-red spot"
  - retinal edema
  - cotton wool spots (retinal infarcts)
  - cholesterol emboli (Hollenhorst plaques) – usually located at arteriole bifurcations

Treatment for a CRAO must be initiated within 2 h of symptom onset for any hope of restoring vision

The "blood and thunder" appearance on fundoscopy is very specific for CRVO

Treatment
- **OCULAR EMERGENCY**: attempt to restore blood flow within 2 h (irreversible retinal damage if >90 min of complete CRAO)
- massage the globe (compress eye with heel of hand for 10 s, release for 10 s, repeat for 5 min) to dislodge embolus
- decrease IOP
  - topical β-blocker
  - IV acetazolamide
  - IV mannitol (draws fluid from eye)
  - drain aqueous fluid – anterior chamber paracentesis (carries risk of infection, lens puncture)
- YAG laser embolectomy
- intra-arterial or intravenous thrombolysis
- hyperbaric oxygen therapy

There is an 8-10% risk of developing CRVO or BRVO in the other eye

Central/Branch Retinal Vein Occlusion

Etiology
- second most frequent "vascular" retinal disorder after DR
- exact cause is not known; possible arteriosclerotic changes in the central retinal artery transform the artery into a rigid structure and impinge upon the central retinal vein as they share a common sheath
- predisposing factors: atherosclerotic vascular disease, HTN, DM, glaucoma, hyperviscosity (e.g. sickle cell disease, polycythemia rubra vera, lymphoma, leukemia), drugs (e.g. oral contraceptive pill, diuretics)

Clinical Features
- painless, monocular, gradual, or sudden vision loss
- ± RAPD
- fundoscopy
  - "blood and thunder" appearance
  - diffuse retinal hemorrhages, cotton wool spots, venous engorgement, swollen optic disc, macular edema
- two fairly distinct groups
  - venous stasis/non-ischemic retinopathy
    - no RAPD, VA ~20/80
    - mild hemorrhage, few cotton wool spots
    - resolves spontaneously over weeks to months
    - may regain normal vision if macula unaffected
  - hemorrhagic/ischemic retinopathy
    - usually older patient with deficient arterial supply
    - RAPD, VA ~20/200, reduced peripheral vision
    - more hemorrhages, cotton wool spots, venous congestion
    - poor visual prognosis

Complications
- neovascularization of retina and iris (secondary rubeosis), may lead to secondary glaucoma
- vitreous hemorrhage
- macular edema

Treatment
- retinal laser photocoagulation, anti-VEGF, and/or corticosteroid injection

Effect of Bevacizumab vs. Aflibercept on Visual Acuity among Patients with Macular Edema due to Central Retinal Vein Occlusion – The SCORE2 Randomized Clinical Trial
JAMA 2017;317(20):2072-2087
Purpose: To investigate whether bevacizumab (used off-label) is non-inferior to aflibercept for the treatment of macular edema secondary to central retinal or hemiretinal vein occlusion.
Methods: 362 patients with macular edema due to central retinal or hemiretinal vein occlusion were randomized to either the bevacizumab-treatment group or the aflibercept-treatment group.
Results: At 6 mo, the mean VA letter score (VALS) was 69.3 (a mean increase from baseline of 18.6) in the bevacizumab group and 69.3 (a mean increase from baseline of 18.9) in the aflibercept group (P = 0.001 for noninferiority). Adverse events were rare but were similar between the two groups.
Conclusion: After 6 mo of treatment, bevacizumab was non-inferior to aflibercept with respect to VA. Cost differences between the drugs has important economic implications.

Integrated Results from the COPERNICUS and GALILEO Studies
Clin Ophthalmol 2017;11:1533-1540
Purpose: Comparing the effects of intravitreal aflibercept to sham injection for macular edema caused by CRVO.
Methods: COPERNICUS (n=187) and GALILEO (n=171) were parallel, double-blind, Phase III RCTs. In the COPERNICUS trial, patients in the sham group crossed over to the treatment group at 24-52 wk of the trial. Patients in the GALILEO trial receiving the sham treatment continued to receive sham injections every 4 wk between 24 wk and 52 wk.
Results: At 24 wk, 60.4% of patients receiving intravitreal aflibercept gained ≥15 letters BCVA from baseline compared to 17.0% in the sham group. At 52 wk, 58.5% of patients receiving intravitreal aflibercept gained ≥15 letters compared to 30.1% in the crossover group and 32.4% in the sham group.
Conclusion: Prompt treatment with intravitreal aflibercept is an effective treatment for macular edema following CRVO.

Retinal Detachment

Definition
- cleavage in the plane between the neurosensory retina and the RPE
- three types
  - rhegmatogenous (most common)
    - caused by a tear or hole in the neurosensory retina, allowing fluid from the vitreous to pass into the subretinal space
    - tears may be caused by PVD, degenerative retinal changes, trauma, or iatrogenic complications
    - incidence increases with advancing age, in high myopes, and after ocular surgery/trauma
  - tractional
    - caused by vitreal, epiretinal, or subretinal membrane pulling the neurosensory retina away from the underlying RPE
    - found in conditions such as DR, RVO, sickle cell disease, ROP, and ocular trauma
  - exudative
    - caused by vascular transudation of fluid or damage to the RPE resulting in fluid accumulation in the subretinal space
    - main causes are intraocular tumour, posterior uveitis, central serous retinopathy

Clinical Features
- sudden onset
- flashes of light
  - due to mechanical stimulation of the retinal photoreceptors
- floaters
- hazy spots in the line of vision which move with eye position
  - due to drops of blood from torn vessels bleeding into the vitreous
- curtain of blackness/peripheral field loss
  - darkness in the field of vision where the retina has detached
- loss of central vision (if macula "off")
- decreased IOP (usually 4-5 mmHg lower than the other, unaffected eye)
- ophthalmoscopy: detached retina is grey-white from retinal edema, and loss of red reflex
- ± RAPD

Treatment
- prophylactic: symptomatic tear (flashes or floaters) can be sealed off with laser/cryotherapy
- therapeutic:
  - rhegmatogenous
    - scleral buckle procedure
    - pneumatic retinopexy
    - pars plana vitrectomy plus injection of gas (injection of silicone oil in cases of recurrent detachment, air travel, or inability to posture postoperative)
  - tractional
    - vitrectomy ± membrane removal/scleral buckling/injection of intraocular gas or silicone oil as necessary
  - exudative
    - management is nonsurgical; any underlying disease should be treated if possible

Complications
- loss of vision, vitreous hemorrhage, recurrent RD
- RD is an emergency, especially if the macula is still attached (macula "on")
- prognosis for visual recovery varies inversely with the amount of time the retina is detached and whether the macula is attached or not

Retinitis Pigmentosa

Definition
- hereditary degenerative disease of the retina manifested by photoreceptor degeneration (rods affected to a greater extent than cones) and atrophy
- many forms of inheritance, most commonly autosomal recessive (60%)

Clinical Features
- night blindness, decreased peripheral vision ("tunnel vision"), decreased central vision (macular changes), glare (from posterior subcapsular cataracts, common)

Investigations
- fundoscopy: areas of "bone-spicule" pigment clumping in mid-periphery of retina, narrowed retinal arterioles, pale optic disc
- electrophysiological tests: electroretinography (ERG) and electrooculography (EOG)

Treatment
- gene treatments have the potential to reverse the condition; cataract extraction improves visual function
- vitamin A supplementation can reduce progression of disease in some patients; avoid vitamin E supplementation
- Voretigene neparvovec-rzyl (Luxturna®) is an FDA-approved novel gene therapy for children and adult patients with biallelic RPE65 mutation-associated retinal dystrophy

Age-Related Macular Degeneration

Definition
- leading cause of irreversible blindness in industrialized countries, associated with increasing age, usually bilateral but asymmetric

Classification
- **Non-Exudative/"Dry" (Non-Neovascular) AMD**
  - most common type of AMD (90% of cases)
  - slowly progressive loss of visual function
  - drusen: yellow deposits between the RPE and Bruch's membrane
  - geographic atrophy: coalescence of RPE atrophy, clumps of focal hyperpigmentation or hypopigmentation
  - may progress to neovascular AMD
- **Exudative/"Wet" (Neovascular) AMD**
  - 10% of AMD cases; however, responsible for 80% of AMD-related vision loss
  - choroidal neovascularization: drusen predisposes to breaks in Bruch's membrane causing subsequent growth and proliferation of new, fine choroidal vessels
  - may lead to serous detachment of overlying RPE and retina, hemorrhage, and lipid precipitates into the subretinal space
  - can also lead to an elevated subretinal mass due to fibrous metaplasia of subretinal fibrovascular proliferation that progresses to disciform scarring and severe central vision loss

Efficacy and Safety of Widely Used Treatments for Macular Edema Secondary to Retinal Vein Occlusion: A Systematic Review
BMC Ophthalmol 2014;14:17
Purpose: To assess the efficacy of widely used treatments for macular edema (ME) secondary to retinal vein occlusion (RVO). ME secondary to RVO can cause vision loss due to CRVO or a BRVO.
Outcomes: Mean change in BCVA from baseline and/or number of patients gaining at least 10 letters from baseline to 6 mo or equivalent time point.
Results: 14 unique RCTs identified. Ranibizumab 0.5 mg produced greater improvements in BCVA at 6 mo compared to sham in BRVO (mean difference 11 letters; 95% CI 7.83-14.17) and CRVO (mean difference 14 letters; 95% CI 10.51-17.69). Improvements in BCVA were also observed with dexamethasone 0.7 mg intravitreal implant (IVT) compared with sham in patients with BRVO or CRVO (mean difference 2.5 letters; 95% CI 0.7-4.3). The difference was significant with BRVO alone, but not CRVO alone. At 36 mo in a large prospective RCT, a greater proportion of patients with BRVO gained >15 letters with laser therapy vs. no treatment (OR 3.16; 95% CI 1.25-8.00), whereas no difference was observed in a 9 mo endpoint in a smaller study. Three studies showed no benefit for laser therapy in CRVO.
Conclusions: Both IVT ranibizumab and dexamethasone show significant improvements over previously accepted standard of care (laser therapy) for the treatment of BRVO and CRVO.

Superotemporal retina is the most common site for horseshoe tears

Retinitis Pigmentosa Inherited Forms
- Autosomal recessive: most common
- Autosomal dominant: best prognosis
- X-linked: worst prognosis

Triad of Retinitis Pigmentosa
APO
Arteriolar narrowing
Perivascular bone spicule pigmentation
Optic disc pallor

Risk Factors
- female
- increasing age
- family history
- smoking
- White individuals
- blue irides

Clinical Features
- variable degree of progressive central vision loss
- metamorphopsia (distorted vision characterized by straight parallel lines appearing convergent or wavy) due to macular edema

Investigations
- Amsler grid: held at normal reading distance with glasses on, assesses macular function
- fluorescein angiography: assesses type and location of choroidal neovascularization – pathologic new vessels leak dye
- OCT retinal imaging: assesses the amount of intraretinal and subretinal exudation

Treatment
- non-neovascular "dry" AMD
  - monitor, Amsler grid allows patients to check for metamorphopsia
  - low vision aids (e.g. magnifiers, closed-circuit television)
  - anti-oxidants, green leafy vegetables
  - sunglasses/visors
  - see Age-related Eye Disease Study 2 (AREDS2) in sidebar
- neovascular "wet" AMD
  - see *Common Medications*, OP44
  - intravitreal injection of anti-VEGF
    - pegaptanib (Macugen®), ranibizumab (Lucentis®), bevacizumab (Avastin®), aflibercept (Eylea®), brolucizumab (Beovu®) (see *VEGF Inhibitors*, OP45)
  - no definitive treatment for disciform scarring
  - photodynamic therapy with verteporfin (Visudyne®)
    - IV injection of verteporfin, followed by low-intensity laser to area of choroidal neovascularization

Age-Related Eye Disease Study 2 (AREDS2) Lutein + Zeaxanthin and Omega-3 Fatty Acids for AMD: The Age-Related Eye Disease Study 2 (AREDS2) Randomized Clinical Trial
JAMA 2013;309(19):2005-2015
See Landmark Ophthalmology Trials table for more information on Age-Related Eye Disease Study 2 (AREDS2), which details whether adding lutein + zeaxanthin, docosahexanoic acid (DHA) + eicosapentanoic acid (EPA), or both to the AREDS formulation decreases the risk of developing advanced AMD and to evaluate the effect of eliminating β-carotene, lowering zinc doses, or both in the AREDS formulation in patients at risk for advanced AMD.

Ten Year Follow-Up of Age-Related Macular Degeneration in the Age-Related Eye Disease Study: AREDS Report No. 36
JAMA Ophthalmol 2014;132(3):272-277
Study: Randomized clinical trial.
Purpose: To describe 10 yr progression rates to intermediate or advanced AMD.
Patients: Age-related eye disease study (AREDS) participants were observed for an additional 5 yr after RCT completion. Participants ages 55-80 yr with no AMD or AMD of varying severity (n=4757) were followed up in the AREDS trial for a median duration of 6.5 yr. When the trial ended, 3549 of the 4203 surviving participants were followed for 5 additional yr.
Intervention: Treatment with antioxidant vitamins and minerals.
Main Outcome: Development of varying stages of AMD and changes in VA.
Results: The risk of progression to advanced AMD increased with increasing age (P=0.01) and severity of drusen. Women (P=0.005) and current smokers (P<0.001) were at increased risk of neovascular AMD. In the oldest participants with the most severe AMD status at baseline, the risks of developing neovascular AMD and central geographic atrophy by 10 yr were 48.1% and 26.0%, respectively. Similarly, rates of progression to large drusen increased with increasing severity of drusen at baseline, with 70.9% of participants with bilateral medium drusen progressing to large drusen and 13.8% to advanced AMD in 10 yr. Median VA at 10 yr in eyes that had large drusen at baseline but never developed advanced AMD was 20/25; eyes that developed advanced AMD had a median VA of 20/200.
Conclusion: The natural history of AMD demonstrates relentless loss of vision in persons who developed advanced AMD.

Glaucoma

Definition
- progressive, irreversible, pressure-sensitive optic neuropathy involving characteristic structural changes to optic nerve head with associated visual field changes
- commonly associated with high IOP, but not required for diagnosis

Background
- aqueous is produced by the ciliary body and drains into the episcleral veins via the trabecular meshwork and Canal of Schlemm
- an isolated increase in IOP is termed ocular hypertension (OHT) - should be followed for increased risk of developing glaucoma
- IOP >21 mmHg increases the risk of developing glaucoma
- loss of peripheral vision most commonly precedes central vision loss
- structural changes commonly precede functional changes

Investigations
- VA testing
- slit-lamp exam to assess anterior chamber depth; gonioscopy to assess angle (open or closed)
- ophthalmoscopy to assess the disc features
- tonometry to measure IOP
- automated perimetry (formal visual field testing)
- pachymetry to measure corneal thickness
- OCT of the retinal nerve fibre layer (NFL) at the optic nerve to monitor for loss of NFL
- OCT of the macular ganglion cell layer-inner plexiform layer (GCIPL) to monitor for loss of GCIPL
- follow-up includes optic disc examination, IOP measurement, OCT of the retinal NFL and macular GCIPL and visual field testing to monitor course of disease

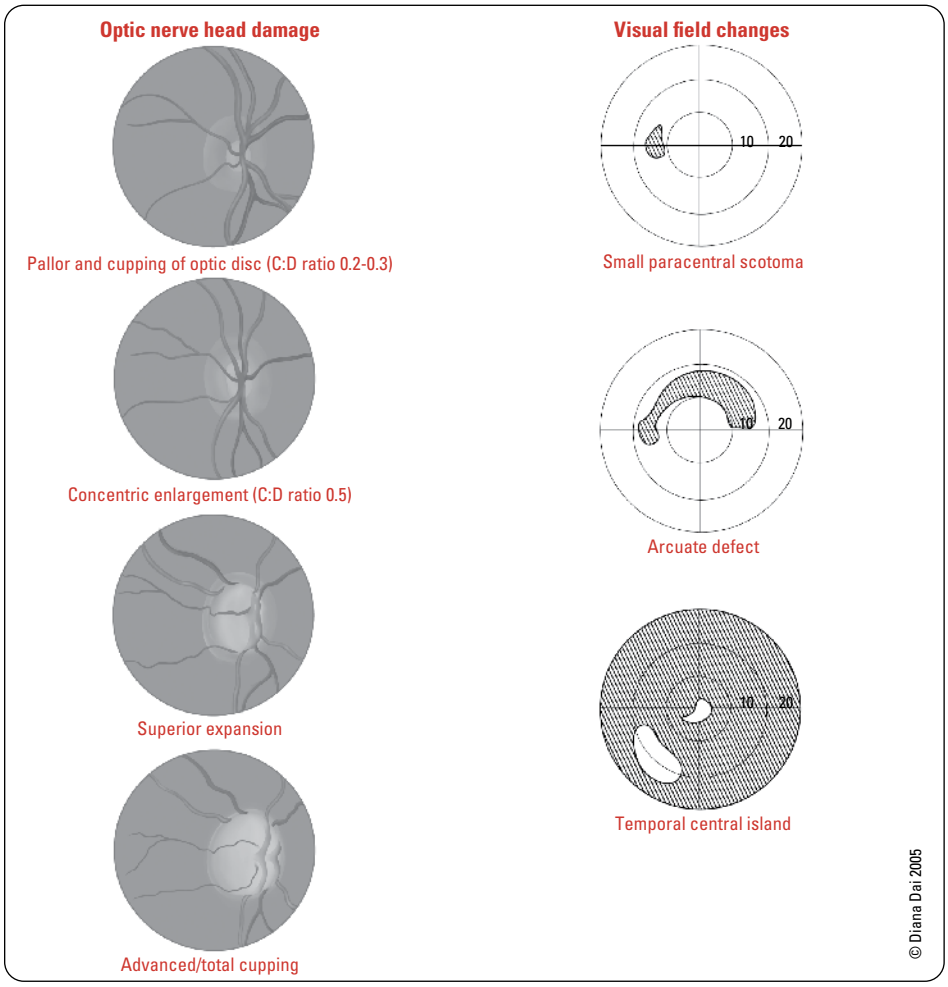

Figure 18. Glaucomatous damage

Average IOP: 15±3 mmHg
Normal CDR: ≤0.4
Suspect glaucoma if CDR >0.6, CDR differs between eyes by >0.2, or cup approaches disc margin

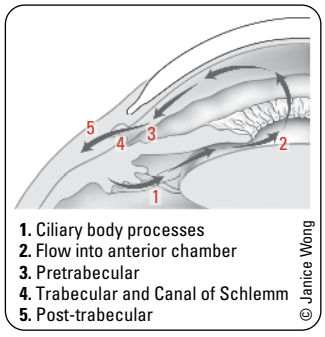

Figure 19. Aqueous flow and sites of potential resistance

Primary Open-Angle Glaucoma

Definition

- most common type, >95% of all glaucoma cases
- unobstructed open-angle, resistance is within the trabecular meshwork
- insidious and asymptomatic, screening is critical for early detection

Major Risk Factors

- ocular hypertension (IOP >21 mmHg)
- age: prevalence at 40 yr is 1-2% and at 80 yr is 10%
- ethnicity: African descent
- familial (2-3x increased risk); polygenic
- thin central cornea (OHTS trial)

Minor Risk Factors

- myopia
- HTN
- DM
- hyperthyroidism (Graves' disease)
- chronic corticosteroid use (topical significantly higher risk than oral)
- previous ocular trauma
- anemia/hemodynamic crisis (ask about blood transfusions in past)

Clinical Features

- asymptomatic initially
- insidious, painless, gradual rise in IOP due to restriction of aqueous outflow
- bilateral, but usually asymmetric
- earliest signs are optic disc changes
  - increased CDR (vertical CDR >0.6)
  - significant CDR asymmetry between eyes (>0.2 difference)

Risk Factors for POAG
A FIAT
Age
Family history
IOP
African descent
Thin cornea

Open- and Closed-Angle Glaucoma

POAG	PACG
Common (95%)	Rare (5%)
More common in Black and Hispanic individuals	More common in Asian and Indigenous Canadians
Chronic course	Acute or chronic onset
Painless eye without redness	Painful red eye
Moderately high IOP	Extremely high IOP
Normal cornea and pupil	Hazy cornea Mid-dilated pupil unreactive to light
No N/V	±N/V, abdominal pain
No halos around light	Halos around light

  - thinning, notching of the neuroretinal rim
  - flame-shaped disc hemorrhage
  - 360° of peripapillary atrophy
  - NFL defect
  - large vessels become nasally displaced
  - retinal NFL vertical thinning on OCT
  - GCIPL thinning on OCT
- visual field loss
- slow, progressive, irreversible loss of peripheral vision
- paracentral defects, arcuate scotoma, and nasal step are characteristics (see Figure 18, OP27)
- late loss of central vision if untreated

Treatment
- medical treatment: decrease IOP by increasing the drainage and/or decreasing the production of aqueous (see Table 14, *Glaucoma Medications,* OP44)
  - increase aqueous outflow
    - topical prostaglandin analogues
    - topical α2-adrenergics
    - topical cholinergics/parasympathomimetics
  - decrease aqueous production
    - topical β-blockers
    - topical and oral carbonic anhydrase inhibitors
    - topical α2-adrenergics
- laser trabeculoplasty, cyclophotocoagulation in order to achieve selective destruction of ciliary body (for refractory cases)
- trabeculectomy: creation of a new outflow tract from anterior chamber to under the conjunctiva forming a bleb
- minimally invasive glaucoma surgery (MIGS): implantation of IOP lowering drainage devices (e.g. iStent, Xen, Hydrus); high safety profile, primarily used for modest IOP reductions in patients with mild-to-moderate glaucoma
- tube shunt (Ahmed, Baerveldt): for advanced stages of glaucoma
- serial optic nerve head examinations, IOP measurements, OCT of retinal NFL and GCIPL, and visual field testing to monitor disease course

Elevated IOP is the only modifiable risk factor that has been proven to prevent progression of glaucoma. Treating patients with ocular hypertension but no signs of glaucoma has also been shown to reduce the risk of developing glaucoma.

The Ocular Hypertension Treatment Study
Arch Ophthalmol-Chic 2002;120:701-713
See Landmark Ophthalmology Trials table for more information on The Ocular Hypertension Treatment Study, which details the safety and efficacy of topical ocular hypotensive medication in delaying or preventing the onset of POAG.

Normal Tension Glaucoma

Definition
- POAG with IOP in normal range
- often found in women >60 yr, but may occur earlier
- associated with migraines, peripheral vasospasm, systemic nocturnal hypotension, and sleep apnea
- damage to optic nerve may be due to vascular insufficiency

Treatment
- treat reversible causes

Secondary Open-Angle Glaucoma

Definition
- increased IOP secondary to ocular/systemic disorders that obstruct the trabecular meshwork including:
  - steroid-induced glaucoma, traumatic glaucoma, pigment dispersion syndrome, pseudoexfoliation syndrome

Rule of Fours
1/4 of general population using topical steroid for 4 wk, 4x/d will develop an increase in IOP

Primary Angle-Closure Glaucoma

Definition
- 5% of all glaucoma cases
- peripheral iris bows forward obstructing aqueous access to the trabecular meshwork
- sudden forward shift of the lens-iris diaphragm causes pupillary block and results in impaired drainage, leading to a sudden rise in IOP

Risk Factors
- hyperopia: small eye, big lens – large lens crowds the angle
- age >70 yr
- female
- family history
- more common in people of Asian and Inuit descent
- mature cataracts
- shallow anterior chamber
- pupil dilation (topical and systemic anticholinergics, stress, darkness)

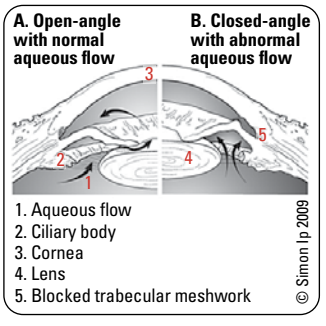

Figure 20. Normal open-angle vs. angle-closure glaucoma

Clinical Features
- red, painful eye with acute presentation = **RED FLAG**
- unilateral, but other eye at increased risk
- decreased VA, vision acutely blurred from corneal edema
- halos around lights
- nausea and vomiting, abdominal pain
- fixed, mid-dilated pupil
- marked increase in IOP; may be noticeable even to palpation (>40 mmHg)
- shallow anterior chamber ± cells in anterior chamber

Complications
- irreversible loss of vision within hours to days if untreated
- permanent peripheral anterior synechiae, resulting in permanent angle closure

Treatment
- OCULAR EMERGENCY: refer to ophthalmologist for acute angle-closure glaucoma
- medical treatment (see Table 14, *Glaucoma Medications,* OP44)
  - aqueous suppressants and hyperosmotic agents such as oral glycerine or IV mannitol
  - miotic drops (pilocarpine) to reverse pupillary block
  - multiple topical IOP-lowering agents
- laser iridotomy is definitive

Angle-Closure Glaucoma

BACH
Tx with miotics and β-blockers
Adrenergics
Cholinergics
Hyperosmotic agents

Collaborative Normal Tension Glaucoma Study
Curr Opin Ophthalmol 2003;14:86-90
Treatment aimed at lowering IOP by 30% in patients with normal tension glaucoma tends to reduce the rate of visual field loss. Due to variability in disease progression and a significant group that shows no visual field loss at 5 yr despite no treatment, further studies are needed to delineate which subgroups may benefit most from treatment.

Secondary Angle-Closure Glaucoma

Uveitis
- inflamed iris adheres to lens (posterior synechiae)

Neovascular Glaucoma
- abnormal blood vessels develop on surface of iris (rubeosis iridis), in the angle, and within the trabecular meshwork
- due to retinal ischemia associated with PDR or CRVO
- treatment with laser therapy to retina reduces neovascular stimulus to iris and angle vessels

Pupils

- pupil size is determined by a delicate balance between the sphincter and dilator muscle tone
- sphincter muscles are innervated by the parasympathetic nervous system carried by CN III
- dilator muscles are innervated by the sympathetic nervous system (SNS)
  - first-order neuron = hypothalamus ➔ brainstem ➔ spinal cord
  - second-order/preganglionic neuron = spinal cord ➔ sympathetic trunk via internal carotid artery ➔ superior cervical ganglion in neck
  - third-order/postganglionic fibres originate in the superior cervical ganglion, neurotransmitter is norepinephrine
- see Neurology, Figure 8, N8

5 Targets of Retinal Signals
- Pretectal nucleus (pupillary reflex/eye movements)
- Lateral geniculate body of thalamus
- Superior colliculus (eye movements)
- Suprachiasmatic nucleus (optokinetic)
- Accessory optic system (circadian rhythm)

Pupillary Light Reflex

- light shone directly into eye travels along optic nerve (CN II, afferent limb) ➔ optic tracts ➔ bilateral midbrain
- impulses enter bilaterally in midbrain via pretectal area and Edinger-Westphal nuclei
- nerve impulses then travel down CN III (efferent limb) bilaterally to reach the ciliary ganglia, and finally to the iris sphincter muscle, which results in the direct and consensual light reflexes
- receptors involved:
  - α1 – pupillary dilator muscle contraction (mydriasis)
  - β2 – ciliary muscle relaxation (non-accommodation); increased aqueous humour production
  - M3 – pupillary sphincter contraction (miosis); increased ciliary muscle contraction (accommodation)

Pupil Abnormalities

Denervation Hypersensitivity
- when postganglionic fibres are damaged, the under-stimulated end-organ attempts to compensate by developing an increase of neuroreceptors and becomes hypersensitive
- postganglionic parasympathetic lesions (i.e. Adie's pupil)
  - pupil will constrict with pilocarpine 0.125% (cholinergic agonist), normal pupil will not
- postganglionic sympathetic lesions (i.e. Horner's syndrome)
  - Horner's pupil will dilate with apraclonidine 0.5-1%, normal pupil will not (reversal of anisocoria)

Local Disorders of Iris

- posterior synechiae (adhesions between iris and lens) due to iritis can present as an abnormally shaped pupil
- ischemic damage (e.g. post-acute angle-closure glaucoma) usually occurs at 3 and 9 o'clock positions resulting in a vertically oval pupil that reacts poorly to light
- trauma (e.g. blunt trauma or post-intraocular surgery)

Anisocoria

- unequal pupil size
- idiopathic/physiologic anisocoria
  - 20% of population
  - round, regular, <1 mm difference
  - pupils reactive to light and accommodation
  - responds normally to mydriatics/miotics
  - post eye surgery, or extensive retinal laser treatment

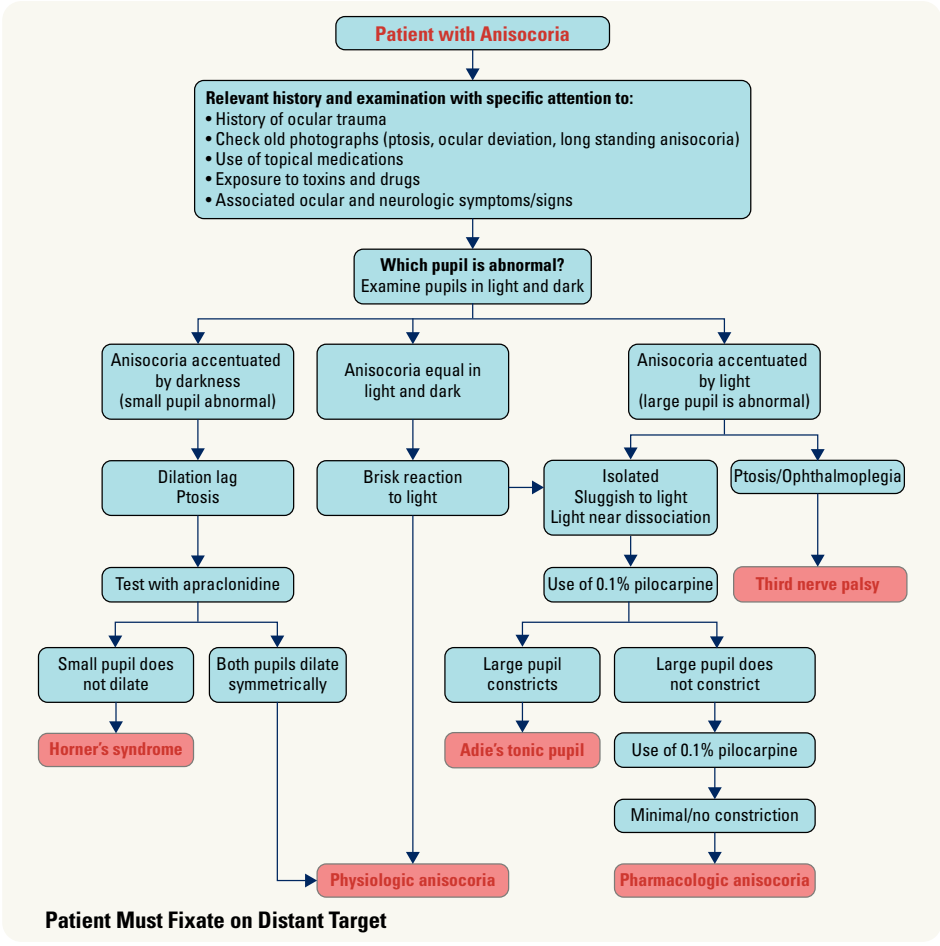

Figure 21. Approach to anisocoria

Reproduced with permission from: Kedar S, Biousse V, Newman NJ. Approach to the patient with anisocoria. In: UpToDate, Rose, BD (editor), UpToDate, Waltham, MA, 2011. Copyright 2011 UpToDate, Inc. For more information visit www.uptodate.com.

Table 9. Summary of Conditions Causing Anisocoria

	Features	Site of Lesion	Light and Accommodation	Anisocoria	Effect of Pilocarpine
ABNORMAL MIOTIC PUPIL (impaired pupillary dilation)					
Horner's Syndrome	Round, unilateral, ptosis, anhidrosis, pseudoenophthalmos	Sympathetic system	Both brisk	Greater in dark	N/A
Argyll-Robertson Pupil	Irregular, usually bilateral	Midbrain	Poor in light; better to accommodation		N/A
ABNORMAL MYDRIATIC PUPIL (impaired pupillary constriction)					
Adie's Tonic Pupil	Irregular, larger in bright light	Ciliary ganglion	Poor in light, better to accommodation	Greater in light	Constricts (hypersensitivity to dilute pilocarpine)
CN III Palsy	Round	Superficial CN III	± fixed (acutely) at 7-9 mm	Greater in light	Constricts
Pharmacologic Dilation	Round, uni- or bilateral	Iris sphincter	Fixed at 7-8 mm	Greater in light	Will not constrict

Dilated Pupil (Mydriasis)

Sympathetic Stimulation
- fight or flight response
- mydriatic drugs: epinephrine, phenylephrine

Parasympathetic Under-Stimulation
- cycloplegics/mydriatics: atropine, tropicamide, cyclopentolate (parasympatholytic)
- CN III palsy
  - eye deviated down and out with ptosis present
  - etiology includes microvascular ischemia (associated with vascular risk factors), vasculitis (e.g. GCA), compression (e.g. pituitary adenoma or posterior communicating artery aneurysm), or midbrain stroke

Acute Angle-Closure Glaucoma
- fixed, mid-dilated pupil

Adie's Tonic Pupil
- 80% unilateral, F>M
- pupil is tonic or reacts poorly to light (both direct and consensual) but constricts with accommodation
- caused by benign lesion in ciliary ganglion; results in denervation hypersensitivity of parasympathetically innervated constrictor muscle
  - dilute (0.125%) solution of pilocarpine will constrict tonic pupil but have no effect on normal pupil
- long-standing Adie's pupils are smaller than unaffected eye

Trauma
- damage to iris sphincter from blunt or penetrating trauma
- iris transillumination defects may be apparent using ophthalmoscope or slit-lamp
- pupil may be dilated (traumatic mydriasis) or irregularly shaped from tiny sphincter ruptures

Constricted Pupil (Miosis)

Senile Miosis
- decreased sympathetic stimulation with age

Parasympathetic Stimulation
- local or systemic medications such as:
  - cholinergic agents: pilocarpine, carbachol
  - opiates, barbiturates

Horner's Syndrome
- lesion in sympathetic pathway
- difference in pupil size greater in dim light, due to decreased innervation of adrenergics to iris dilator muscle
- associated with ptosis and anhidrosis of ipsilateral face/neck (in pre-ganglionic lesions)
- apraclonidine (strong α-2 and weak α-1 blocker) is the most common pharmacologic diagnostic test, in which denervation hypersensitivity results in dilation of the Horner pupil but not the normal pupil (leading to reversal of anisocoria)

CN III palsy with pupillary involvement may be associated with a posterior communicating artery aneurysm

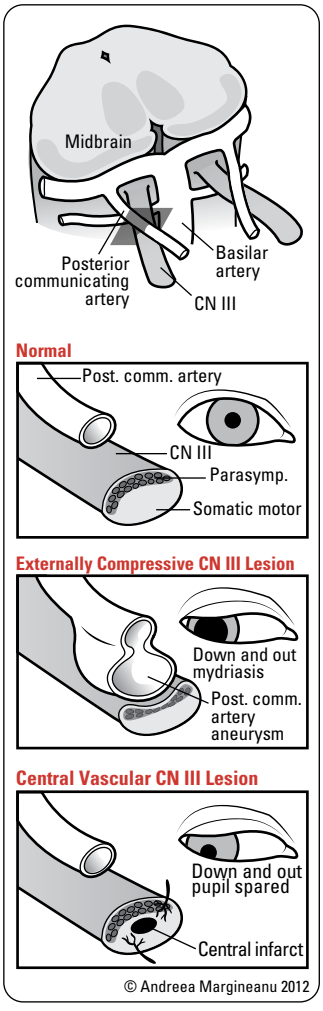

Figure 22. CN III lesions with and without mydriasis

- application of cocaine 4-10% (blocks reuptake of norepinephrine) to eye does not result in pupil dilation (vs. physiologic anisocoria), therefore confirming the diagnosis
- hydroxyamphetamine 1% (stimulates norepinephrine release) will dilate pupil if central or preganglionic lesion, not postganglionic lesion
- cocaine and hydroxyamphetamine are rarely used in practice due to issues with availability
- causes: mostly idiopathic but other causes include brainstem infarct (lateral medullary syndrome), Pancoast tumour, neck surgery, and carotid artery aneurysm
- must rule out carotid artery dissection in acute Horner's syndrome (<14 days old)

Horner's MAP
Miosis
Anhidrosis
Ptosis

Iritis
- miotic pupil initially
- can become irregularly shaped pupil due to posterior synechiae
- later stages non-reactive to light

Argyll-Robertson Pupil
- both pupils irregular and <3 mm in diameter, ± ptosis
- does not respond to light stimulation
- responds to accommodation (light-near dissociation)
- suggestive of neurosyphilis or other conditions (DM, encephalitis, MS, chronic alcoholism, CNS degenerative diseases)

Relative Afferent Pupillary Defect

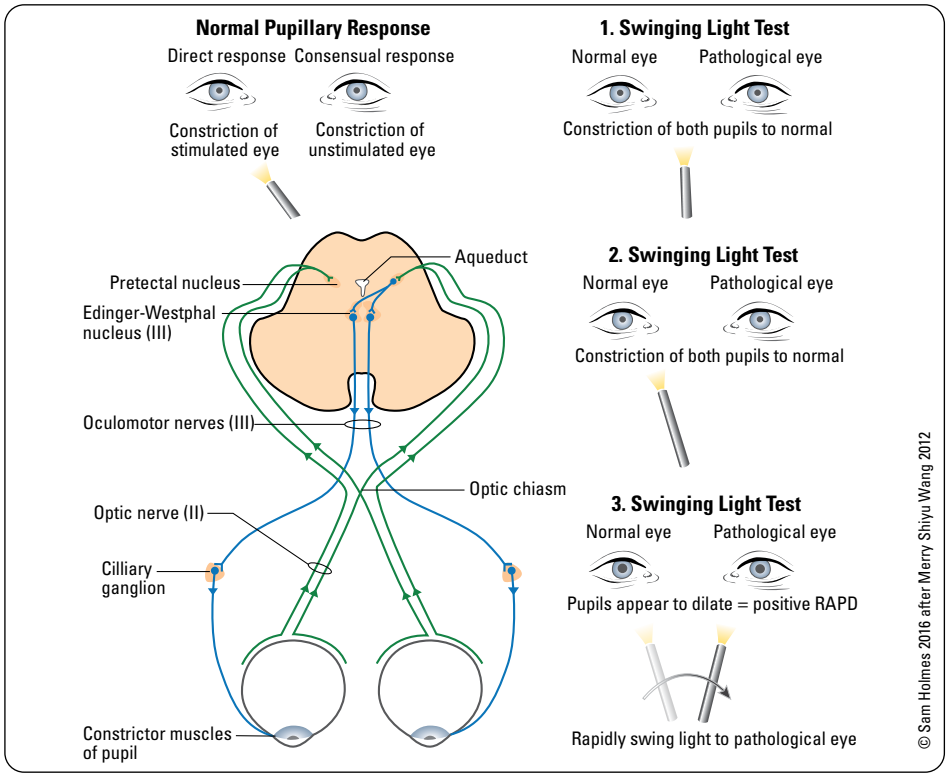

Figure 23. Relative afferent pupillary defect

- also known as Marcus Gunn pupil
- impairment of direct pupillary response to light caused by a lesion in visual afferent (sensory) pathway, anterior to optic chiasm
- differential diagnosis: any unilateral or asymmetric optic neuropathy (e.g. optic neuritis, ischemic optic neuropathy, compressive optic neuropathy) or severe retinopathy (e.g. CRAO, large BRAO, large RD, CRVO)
- does not occur with media opacity (e.g. corneal edema, cataracts) or if optic neuropathy is symmetric (since it is relative)
- pupil reacts poorly to light and better to accommodation
- test: swinging flashlight
  - if light is shone in the affected eye, direct and consensual response to light is decreased
  - if light is shone in the unaffected eye, direct and consensual response to light is normal
  - if the light is moved quickly from the unaffected eye to the affected eye, "paradoxical" dilation of both pupils occurs
  - observe red reflex, especially in patients with dark irides

Cataracts never produce a RAPD

Differentiate RAPD from physiologic pupillary athetosis ("hippus"), which is rapid, rhythmic fluctuations of the pupil, with equal amplitude in both eyes

Malignancies

- uncommon site for 1° malignancies
- see *Retinoblastoma*, OP40

Lid Carcinoma

Etiology
- basal cell carcinoma (90%)
  - spread via local invasion, rarely metastasizes
  - ulcerated centre (rodent ulcer), indurated base with pearly rolled edges, telangiectasia
- squamous cell carcinoma (<5%)
  - spread via local invasion, may also spread to nodes and metastasize
  - ulceration, keratosis of lesion
- sebaceous cell carcinoma (1-5%)
  - often masquerades as chronic blepharitis or recurrent chalazion
  - highly invasive, metastasizes
- other: Kaposi's sarcoma, malignant melanoma, Merkel cell carcinoma, metastatic tumour

To Find Small Ocular Melanoma

TFSOM
Thickness >2 mm
Subretinal Fluid
Symptoms – vision changes
Orange pigment
Margin within 3 mm of optic disc

Treatment
- incisional or excisional biopsies
- may require cryotherapy, radiotherapy, chemotherapy, immunotherapy
- surgical reconstruction

Uveal Melanoma

Etiology
- most common 1° intraocular malignancy in adults
- more prevalent in White individuals
- arise from uveal tract, 90% choroidal melanoma
- hepatic metastases predominate

Clinical Features
- classic appearance of a pigmented dome-shaped mass extending from the ciliary body or the choroid
- diagnosis necessitates expertise of an ophthalmologist/ocular oncologist
- despite treatment, has the possibility of remaining dormant and resurfacing with metastasis years later

Treatment
- investigations: ocular ultrasound, fluorescein angiography, OCT, and systemic cancer investigations
- depending on the size of the tumour, either radiotherapy (brachytherapy vs. external beam), or enucleation

Metastases

- most common intraocular malignancy in adults
- most commonly from breast and lung in adults, neuroblastoma in children
- usually infiltrate the choroid, but may also affect the optic nerve or extraocular muscles
- may present with decreased or distorted vision, irregularly shaped pupil, iritis, and hyphema

Treatment
- local radiation, chemotherapy
- enucleation if blind, painful eye, or large tumour

Ocular Manifestations of Systemic Disease

HIV/AIDS

- up to 75% of patients with AIDS have ocular manifestations

External Ocular Signs
- Kaposi's sarcoma
  - secondary to human herpes virus 8 (HHV-8), causes bright red conjunctival lesion and subconjunctival hemorrhage
  - differential diagnosis: subconjunctival hemorrhage (non-clearing), hemangioma

- multiple molluscum contagiosum
- herpes simplex/zoster keratitis

Retina

- HIV retinopathy (most common)
  - cotton wool spots in >50% of HIV patients
  - intraretinal hemorrhage
- CMV retinitis
  - ocular opportunistic infection that develops when severely immunocompromised (CD4 count ≤50)
  - a necrotizing retinitis, with retinal hemorrhages and vasculitis, "brushfire" or "pizza pie" appearance
  - presents with scotoma (macular involvement and RD), blurred vision, and floaters
  - untreated infection will progress to the other eye in 4-6 wk
  - treatment: virostatic agents (e.g. ganciclovir or foscarnet) via IV, intravitreal injection, or sometimes PO
- necrotizing retinitis
  - from herpes simplex virus, herpes zoster, toxoplasmosis
  - *Pneumocystis carinii* and *Mycobacterium avium intracellulare* can present with choroiditis
  - *Candida* can present as retinitis and vitritis

Other Systemic Infections

- herpes zoster
  - see *Herpes Zoster Ophthalmicus*, OP19
- candidal endophthalmitis
  - fluffy, white-yellow, superficial retinal infiltrates that may eventually result in vitritis
  - may present with inflammation of the anterior chamber
  - treatment: systemic amphotericin B, oral fluconazole, and voriconazole
- toxoplasmosis
  - focal, grey-yellow-white, chorioretinal lesions with surrounding vasculitis and vitreous inflammation (vitreous cells)
  - can be congenital (transplacental) or acquired (caused by *Toxoplasma gondii* protozoa transmitted through raw meat and cat feces)
  - congenital form more often causes visual impairment (more likely to involve the macula)
  - treatment: pyrimethamine, sulfonamide, folinic acid, or clindamycin. Consider adding steroids after if severe inflammation (vitritis, macular, or optic nerve involvement)

Diabetes Mellitus

- most common cause of blindness in young people in North America
- loss of vision due to:
  - progressive microangiopathy leading to macular edema
  - progressive DR → neovascularization → traction → RD and vitreous hemorrhage
  - rubeosis iridis (neovascularization of the iris) leading to neovascular glaucoma (poor prognosis)
  - macular ischemia

Macular edema is the most common cause of visual loss in patients with background DR

DIABETIC RETINOPATHY

Background

- altered vascular permeability (loss of pericytes and thickening of basement membrane causing breakdown of blood-retinal barrier)
- predisposition to retinal vessel obstruction (CRAO, CRVO, and BRVO)

Clinically significant macular edema is defined as thickening of the retina at or within 500 µm of the centre of the macula

Classification

- non-proliferative: increased vascular permeability and retinal ischemia
  - hard exudates (lipid deposits)
  - dot and blot hemorrhages
  - microaneurysms
  - retinal edema
- advanced non-proliferative (or pre-proliferative)
  - non-proliferative findings plus:
    - venous beading (in ≥2 of 4 retinal quadrants)
    - intraretinal microvascular abnormalities (IRMA) in 1 of 4 retinal quadrants
      - IRMA: dilated, non-leaky collateral vessels within the retina
    - retinal hemorrhages ± microvascular anomalies (MAs) (in all 4 retinal quadrants)
    - retinal nerve fibre layer (NFL) infarcts (i.e. cotton-wool spots)

Presence of DR in
T1DM
- 25% after 5 yr
- 60% after 10 yr
- >80% after 15 yr

T2DM
- 20% at time of diagnosis
- 60% after 20 yr

- proliferative
  - 5% of patients with DM will reach this stage
  - neovascularization of iris, disc, retina
    - neovascularization of iris (rubeosis iridis) can lead to neovascular glaucoma
    - vitreous hemorrhage, bleeding from fragile new vessels, fibrous tissue can contract causing tractional RD
  - may remain asymptomatic in early stage
  - high-risk of severe vision loss secondary to vitreous hemorrhage, RD

Screening Guidelines for Diabetic Retinopathy

- T1DM
  - screen for retinopathy beginning annually 5 yr after disease onset
  - annual screening indicated for all patients over 12 yr and/or entering puberty
- T2DM
  - initial examination at time of diagnosis, then annually
- pregnancy
  - ocular exam in 1st trimester, close follow-up throughout, as pregnancy can exacerbate DR
  - patients with gestational diabetes are not at risk of having DR

Treatment

- 1° prevention: tight control of blood glucose, blood pressure, serum lipid levels, kidney function, and microvascular complications (Diabetic Control and Complications Trial (DCCT))
- 2° prevention: regular screening to monitor for progression
- 3° prevention:
  - pan-retinal laser photocoagulation (PRP) for PDR: reduces neovascularization, hence reducing the angiogenic stimulus from ischemic retina by decreasing retinal metabolic demand ➡ reduces risk of blindness
  - intravitreal injection of corticosteroid or anti-VEGF for fovea-involved diabetic macular edema
  - macular photocoagulation laser for clinically significant macular edema (when not involving centre of macula)
  - vitrectomy for non-clearing vitreous hemorrhage ± tractional RD in PDR
    - vitrectomy before vitreous hemorrhage does not improve the visual prognosis

LENS CHANGES

- earlier onset of senile nuclear sclerotic and cortical cataracts
- may get hyperglycemic cataract due to sorbitol accumulation (rare)
- changes in blood glucose levels (poor control) can suddenly cause refractive changes by 3-4 diopters due to induced osmotic changes of the lens

EXTRAOCULAR MUSCLE PALSY

- usually CN III infarct
- pupil usually spared in diabetic CN III palsy, but ptosis is observed
- may involve CN IV and VI
- usually recover within few months

OPTIC NEUROPATHY

- VA loss due to infarction of optic disc/nerve

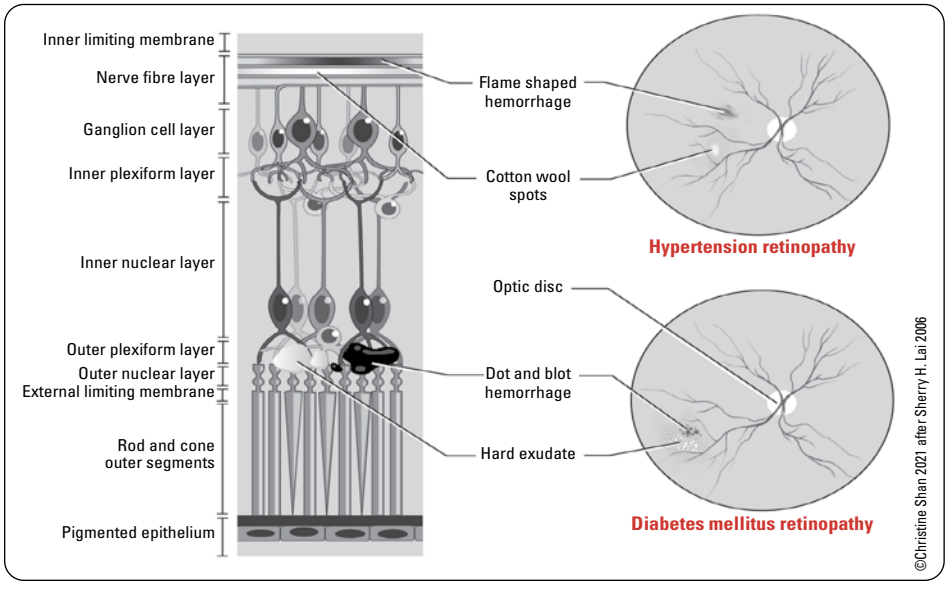

Figure 24. DM vs. HTN retinopathy

Anti-Vascular Endothelial Growth Factor for Diabetic Macular Oedema: A Network Meta-Analysis
Cochrane DB Syst Rev 2018;10:CD007419
Purpose: To compare the effectiveness and safety of the different anti-VEGF drugs using network meta-analysis methods.
Results: Included 24 studies with 6007 patients with DMO and moderate vision loss. Aflibercept, bevacizumab, and ranibizumab were all more effective than laser therapy for improving vision by 3 or more lines after one year. Aflibercept may confer some advantage over ranibizumab and bevacizumab. There were no differences in adverse events.
Conclusions: Anti-VEGF drugs are effective at improving vision in people with DMO with three to four in every 10 people likely to experience an improvement of 3 or more lines VA at one year. More evidence on the long-term (greater than two years) comparative effects of these anti-VEGF agents is needed.

Aflibercept, Bevacizumab, or Ranibizumab for Diabetic Macular Edema: 2 Year Result from a Comparative Effectiveness Randomized Clinical Trial
Ophthalmology 2016;123:1351-1359
All 3 anti-VEGF agents showed improvement of VA and decreased number of injections in year 2. Among eyes with worse baseline VA, aflibercept had superior 2 yr VA compared with bevacizumab, but superiority over ranibizumab in year 1 was no longer identified.

Effects of Medical Therapies on Retinopathy Progression in T2DM
NEJM 2010;363:233-244
See Landmark Ophthalmology Trials table for more information on Effects of Medical Therapies on Retinopathy Progression in T2DM, which details whether intensive glycemic control, combination therapy for dyslipidemia, and intensive blood pressure control can limit the progression of DR.

Hypertension

- retinopathy is the most common ocular manifestation
- acute HTN retinopathy: retinal arteriolar spasm, superficial retinal hemorrhage, cotton wool spots, optic disc edema
- chronic HTN retinopathy: arteriovenous (AV) nicking, flame/dot/blot retinal hemorrhages, cotton wool spots
- increases risk for many other ocular diseases (DR, BRVO, CRAO/BRAO)

Table 10. Modified Scheie Classification

Classification	
Grade 0	No changes
Grade 1	Mild arterial narrowing
Grade 2	Obvious arterial narrowing with focal irregularities
Grade 3	Grade 2 + retinal hemorrhages and/or exudate
Grade 4	Grade 3 + swollen optic nerve (malignant HTN)

Multiple Sclerosis

- see Neurology, N55

Clinical Features

- blurred vision and decreased colour vision secondary to optic neuritis
- central scotoma due to damage to papillomacular bundle of retinal nerve fibres
- diplopia secondary to INO
- RAPD, ptosis, nystagmus, uveitis, optic atrophy, optic neuritis
- white matter demyelinating lesions of optic nerve on MRI

Treatment

- IV steroids with taper to oral form for optic neuritis
  - DO NOT treat with oral steroids in isolation due to increased risk of developing MS

Corticosteroids for Treating Optic Neuritis
Cochrane DB Syst Rev 2015;8:CD001430
Summary: No conclusive evidence of benefit in terms of recovery to normal VA, visual field, or contrast sensitivity six mo after initiation of IV or oral corticosteroids.
Results: After review of 6 RCTs evaluating systemic corticosteroids for treatment of acute optic neuritis, all meta-analyses show similar outcomes for placebo vs. corticosteroid group for VA, contrast sensitivity, and visual field.

Transient Ischemic Attack/Amaurosis Fugax

- sudden, transient blindness from intermittent vascular compromise
- ipsilateral carotid most frequent embolic source
- typically monocular, lasting <5-10 min
- Hollenhorst plaques (glistening microemboli seen at branch points of retinal arterioles) sometimes seen

Graves' Disease

- ophthalmopathy occurs despite control of thyroid gland status
- ocular manifestations occur mainly due to increased fibroblast proliferation and accumulation of hydrophilic glycosaminoglycans (mostly hyaluronic acid) in the extraocular muscles and orbital tissues

Clinical

- initial inflammatory phase is followed by a quiescent cicatricial phase

Treatment

- treat hyperthyroidism
- monitor for corneal exposure and maintain corneal hydration
- manage diplopia, proptosis, and compressive optic neuropathy with one or a combination of:
  - steroids (during acute phase)
  - orbital bony decompression
  - external beam radiation of the orbit
- consider strabismus and/or eyelid surgical procedures once acute phase subsides

The most common cause of unilateral or bilateral proptosis in adults is Graves' disease

Progression of Signs and Symptoms of Graves' Ophthalmopathy

NO SPECS
No signs/symptoms
Only signs (lid retraction, lid lag)
Soft tissue swelling (periorbital edema)
Proptosis (exophthalmos)
Extraocular muscle weakness (causing diplopia)
Corneal exposure
Sight loss

Connective Tissue Disorders

- RA, juvenile idiopathic arthritis, SLE, Sjögren's syndrome, ankylosing spondylitis, polyarteritis nodosa
- most common ocular manifestation: dry eyes (keratoconjunctivitis sicca)

Giant Cell Arteritis/Temporal Arteritis

- see Rheumatology, RH23

ESR in GCA/Temporal Arteritis
Males >age/2
Females >(age + 10)/2

Clinical Features
- more common in women >60 yr
- sudden loss of vision, pain over the temporal artery, jaw claudication, scalp tenderness, constitutional symptoms, and PMHx of polymyalgia rheumatica
- ischemic optic neuropathy or, less commonly, CRAO often preceded by transient monocular vision loss
- very high risk of vision loss in contralateral eye if untreated

Diagnosis
- CBC (thrombocytosis), elevated ESR and CRP
- temporal artery biopsy

Treatment
- high dose corticosteroid to prevent further ischemic complications and improve systemic symptoms
- if diagnosis of GCA is suspected clinically: start STAT treatment + perform temporal artery biopsy to confirm diagnosis within 2 wk of initial presentation

Sarcoidosis

Clinical Features
- granulomatous uveitis with large "mutton fat" keratic precipitates and posterior synechiae
- complications include glaucoma, cataracts, retinal hemorrhages, peripheral retina neovascularization, and dry eye
- neurosarcoidosis: optic neuropathy, oculomotor abnormalities, visual field loss

Treatment
- topical/systemic steroids and mydriatics

Paediatric Ophthalmology

Strabismus

- ocular misalignment in one or both eyes, can be found in up to 3% of children
- classification
  - manifest (constant) vs. latent (hidden) alignment
  - comitant (deviation equal in all positions of gaze, also known as non-paralytic or concomitant) vs. incomitant (deviation worse in certain positions, also known as paralytic or restrictive)
  - described in direction of deviation relative to the fixating eye
- distinguish from pseudostrabismus (prominent epicanthal folds, hypertelorism)
- complications: amblyopia, cosmesis

Strabismus in children under 4 mo of age sometimes resolves, particularly if the deviation is intermittent, variable, or measures <40 prism diopters

All children with strabismus and/or possible reduced vision require prompt referral to an ophthalmologist

Heterotropia
- manifest deviation
- deviation not corrected by the fusion mechanism (i.e. deviation is apparent when the patient is using both eyes)

Heterophoria
- latent deviation
- deviation corrected in the binocular state by the fusion mechanism (i.e. deviation not seen when patient is focusing with both eyes)
- very common – majority are asymptomatic
- may be exacerbated or become manifest with asthenopia (eye strain, fatigue)

Types
- exo- (lateral deviation), eso- (medial deviation)
- hyper- (upward deviation), hypo- (downward deviation)
- esotropia = "crossed-eyes"; exotropia = "wall-eyed"

Tests
- Hirschberg test (corneal light reflex): positive if the light reflex on both corneas is asymmetrical
  - false positives occur if visual axis and anatomic pupillary axis of the eye are not aligned (angle κ)
  - positive in -tropias; negative in -phorias

- cover-uncover test allows to differentiate between -tropias and -phorias
  - any movement of the non-occluded eye in a single cover test indicates a -tropia, as that eye picks up fixation in the absence of visual input to the dominant eye
  - any movement of the occluded eye in a cover-uncover test indicates a -phoria
- alternate cover test
  - alternating the cover between both eyes reveals the total deviation, both latent and manifest
  - maintain cover over one eye for 2-3 s before rapidly shifting to other eye
  - deviation can be quantified using a prism over one eye (alternate prism cover test)

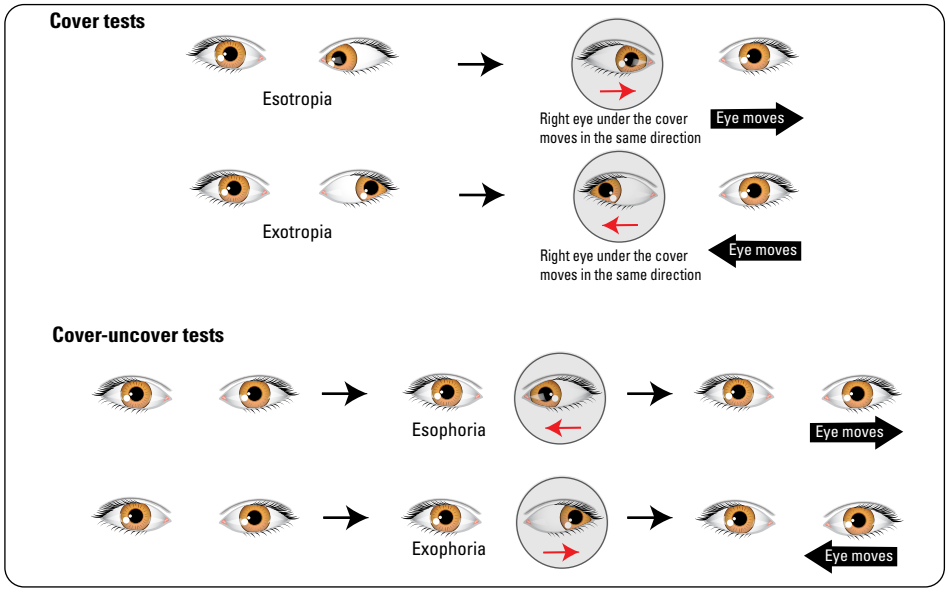

Figure 25. Cover and cover-uncover tests for detection of tropia and phoria

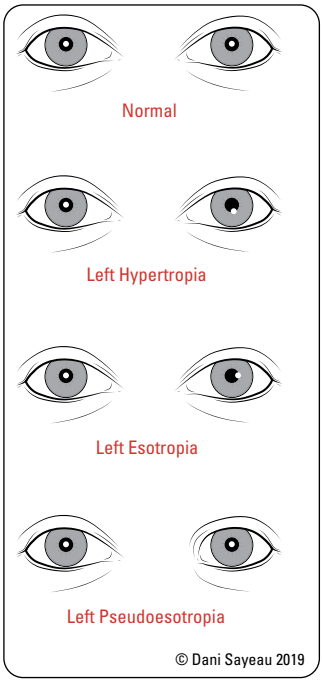

Figure 26. Hirschberg test

Table 11. Paralytic vs. Non-Paralytic Strabismus

Clinical Characteristics	Paralytic Strabismus	Non-Paralytic Strabismus
Definition	Incomitant strabismus	Concomitant strabismus
Onset	Often sudden but may be gradual or congenital	Usually gradual or shortly after birth; rarely sudden
Age of Onset	Any age; most often acquired	Usually during infancy
Etiology	Reduction or restriction in range of eye movements due to: Neural (CN III, IV, VI): ischemia (e.g. DM), MS, aneurysm, brain tumour, trauma Muscular: myasthenia gravis (neuromuscular junction pathology), Graves' disease Structural: restriction or entrapment of extraocular muscles due to orbital inflammation, tumour, fracture of the orbital wall	Develops early in childhood No restriction in range of eye movements Monocular, alternating, or intermittent
Diplopia	Common	Uncommon; image from the misaligned eye is suppressed
Visual Acuity in Other Eye	Usually unaffected in the other eye, unless CN II is involved	Deviated eye may become amblyopic if not treated when the child is young Amblyopia treatment rarely successful after age 8-10 yr Amblyopia usually does not develop if child has alternating strabismus or intermittency, which allows neural pathways for both eyes to develop
Possibility of Amblyopia	Uncommon	Common
Neurologic Findings or Systemic Disease	May be present	Usually absent

Accommodative Esotropia

- normal response to approaching object is the triad of the near reflex: convergence, accommodation, and miosis
- hyperopes must constantly accommodate – excessive accommodation can lead to esotropia in young children via over-activation of the near reflex
- average age of onset is 2.5 yr
- reversible with correction of refractive error
- called partially accommodative esotropia if correction of refractive error only resolves part of the esotropia

Non-Accommodative Esotropia
- accounts for 50% of childhood strabismus
- most are idiopathic
- congenital (or infantile) esotropia is a common and important subtype
- may be due to monocular visual impairment (e.g. cataract, corneal scarring, anisometropia, retinoblastoma) or divergence insufficiency (ocular misalignment that is greater at distance fixation than at near fixation)

Exotropia
- accounts for 11-18% of childhood strabismus
- congenital: onset before 6 mo, may be associated with other conditions (e.g. neurologic, craniofacial disorders)
- acquired
  - intermittent exotropia: typically apparent when patient is tired of looking in the distance
  - sensory exotropia: eye with poorer vision drifts outward (age ≥2 yr)
  - consecutive exotropia: develops after strabismus surgery

Amblyopia

Definition
- most common cause of vision loss in children; a neurodevelopmental visual disorder with unilateral or bilateral (less common) reduction of BCVA that cannot be attributed only to the effect of an ocular structural abnormality
- cannot be remedied immediately by prescription eyewear alone

Etiology
- progressive suppression of visual input from eye receiving suboptimal image (blurry, deviated)
- in approximately half of the cases, amblyopia is secondary to strabismus (mainly esotropia)
- other causes may include uncorrected refractive errors, anisometropia (asymmetric refractive errors, usually in the more hyperopic eye), and deprivation due to structural ocular problems (ptosis, cataract, corneal opacity/scarring, retinoblastoma)

Diagnosis
- "Holler Test": young child upset if good eye is covered
- quantitative VA by age 3-4 yr using picture charts and/or matching game (Sheridan-Gardiner), testing each eye separately

Management
- strabismus
  - correct with glasses for accommodative esotropia
  - occlusion therapy (see below)
  - surgery: recession (weakening) by moving muscle insertion further back on the globe or resection (strengthening) by shortening the muscle
  - botulinum toxin for single muscle weakening
  - after ocular alignment is restored (glasses, surgery, botulinum toxin), patching is frequently necessary to maintain vision until ~8 yr of age
  - no proven value for vision therapy/training in the treatment of strabismus or amblyopia
- anisometropia
  - the eye with the lower refractive error receives a clear image, while the less emmetropic eye receives a blurred image; input from the blurred eye is cortically suppressed and visual pathway fails to develop normally
  - treat with glasses to correct refractive error
  - patching is required if VA difference persists after using glasses for 4-8 wk
- deprivation: treat underlying cause
- amblyopia treatment less successful after age 8-10 yr, but a trial should be given no matter what age
  - prognosis: 90% of strabismic/anisometropic amblyopia will have good vision restored and maintained if treated before age 4 yr, but deprivational has a worse prognosis

Amblyopia Therapy
- occlusion: full or part-time patching of the good eye to force the brain to use the non-dominant eye and redevelop its vision with follow-up to prevent occlusion amblyopia
- cycloplegic drops (e.g. atropine) to impair accommodation and blur vision in the good eye

Risks
- permanent loss of vision in the affected eye
- possibility of injury to "remaining" good eye (e.g. occlusion amblyopia)
- safety glasses or polycarbonate lenses recommended if VA in worse eye is <20/50 to reduce risk of traumatic injury to good eye
- loss of stereopsis

Leukocoria

Definition
- white pupillary reflex (red reflex is absent)
- the presence of leukocoria warrants urgent referral to an ophthalmologist

Differential Diagnosis
- retinoblastoma
- cataract
- Coats disease (exudative retinal telangiectasis)
- persistent hyperplastic primary vitreous or persistent fetal vasculature
- retinal coloboma (chorioretinal)
- RD
- congenital infections (e.g. toxoplasmosis and toxocariasis)
- ROP

Retinoblastoma

Definition
- intraocular malignancy that rapidly develops from immature cells of the retina

Epidemiology
- most common primary intraocular malignancy in children
- incidence: 1/15000
- unilateral (2/3) or bilateral (1/3)
- malignant – direct or hematogenous spread

Etiology
- sporadic or genetic transmission; screening of siblings/offspring essential
- inherited forms likely to be bilateral
- often caused by mutations in RB1 on ch13q14, the first tumour suppressor gene discovered, and less commonly by amplifications of MYCN, an oncogene

Diagnosis
- often presents with leukocoria and/or strabismus
- other signs: red eye, eye enlargement if advanced disease
- fundus examination (nodular, white/cream-coloured masses with intralesional blood vessels)
- U/S (A & B-scan) or MRI may demonstrate RD and/or calcified mass (present in most cases)

Treatment
- local (laser, cryotherapy, chemotherapy), systemic chemotherapy, and/or enucleation + genetic counseling

Retinal Zones
- Zone I: circle centred at the nerve with radius twice the distance from the disc to the macula (most difficult to treat)
- Zone II: annulus from zone I to nasal extent of retina (nasal ora serrata)
- Zone III: remaining retina

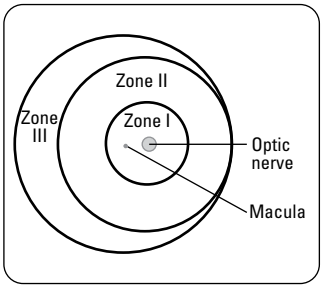

Figure 27. Zones of the retina in ROP

Retinopathy of Prematurity

Definition
- vasoproliferative retinopathy that is a major cause of childhood blindness in low- and middle-income countries

Risk Factors
- non-black race (black infants have lower risk of developing ROP)
- earlier gestational age, birth weight <1500 g, low caloric intake, postnatal hyperglycemia
- high oxygen exposure after birth (iatrogenic), i.e. assisted ventilation >1 wk

Classification (ROP Staging)
- stage 1: flat white demarcation line at the junction between the vascular and avascular retina
- stage 2: elevated ridge
- stage 3: extra-retinal fibrovascular tissue extending into vitreous
- stage 4: partial RD (4A: macula "on", 4B: macula "off")
- stage 5: total RD
- plus (+) disease: dilatation and tortuosity of retinal vessels
- threshold disease: stage 3+ in zones 1 or 2 with circumferential extent of ROP involvement in 5 continuous or 8 cumulative clock hours

Treatment
- laser ablation is currently the treatment standard for stages 3+; intravitreal bevacizumab and ranibizumab both showed significant benefits in zone I compared to laser ablation therapy in infants with stage 3+ ROP
- stage 4-5 is treated with vitrectomy/scleral buckle (goal is to release vitreous tractional forces on the retina)

Anti-VEGF Drugs for Treatment of Retinopathy of Prematurity (ROP)
Cochrane DB Syst Rev 2018;1:CD009734
Summary/Conclusions: Review of 6 RCTs/Quasi-RCTs comparing anti-VEGF agents vs. conventional therapy for ROP (n=383).
- Insufficient data precludes strong conclusions for routine use of intravitreal anti-VEGF agents for treatment of ROP
- Intravitreal bevacizumab/ranibizumab as monotherapy reduces risk of refractory errors during childhood
- Intravitreal pegaptanib + laser therapy reduces the risk of retinal detachment for type 1 ROP
- Effect on other critical outcomes and long-term systemic adverse effects are unknown

Prognosis
- higher incidence of myopia among ROP infants, even if treated successfully (less refractive error among anti-VEGF treated vs. laser treated)
- stage 4B and 5 have poor prognosis for visual outcome despite treatment

Nasolacrimal System Defects

Definition
- congenital obstruction of the nasolacrimal duct (failure of canalization) at valve of Hasner, ~1-2 mo of age

Signs and Symptoms
- epiphora (overflow of tears), periocular crusting, mucopurulent discharge, recurrent conjunctivitis
- can have reflux of mucopurulent material from lacrimal punctum when pressure is applied over lacrimal sac

Treatment
- circular massage over lacrimal sac at medial canthus
- vast majority spontaneously resolve in 9-12 mo, otherwise consider referral for duct probing

Ophthalmia Neonatorum

Gonococcal infection is the most serious threat to sight as it can rapidly penetrate corneal epithelium, causing corneal ulceration

Definition
- purulent conjunctivitis with profuse exudate in the first few days of life; can cause blindness

Etiology
- chemical/toxic: silver nitrate, erythromycin (secondary to prophylaxis, self-limiting)
- infectious: bacterial (e.g. *N. gonorrhoeae* – most common, *C. trachomatis*), herpes simplex virus

Treatment
- systemic antibiotics and saline irrigation with possible hospitalization if infectious etiology

Congenital Glaucoma

Epiphora in children – rule out congenital glaucoma

Definition
- elevated IOP within the first year of life

Etiology
- not entirely known – may be due to inadequate development of anterior chamber
- sporadic and hereditary (autosomal recessive); males more often affected
- secondary congenital glaucoma can be associated with ocular and systemic disorders
  - ocular: aniridia, microcornea, megalocornea, microphthalmos, persistent hyperplastic primary vitreous, Sturge-Weber syndrome, Axenfeld-Rieger syndrome, neurofibromatosis
  - systemic: Prader-Willi, trisomies, fetal alcohol syndrome, mucopolysaccharidoses, and many others

Clinical Features
- photophobia, epiphora, and blepharospasm
- cloudy cornea due to edema; Haab's striae due to breaks in Descemet's membrane
- increased IOP, rapidly-progressive myopia
- buphthalmos (large cornea, "ox eye") and enlarged CDR

Treatment
- immediate angle surgery after diagnosis

Ocular Trauma

Blunt Trauma

Always test VA first – medicolegal protection

- caused by blunt object such as fist
- HPI: injury, ocular history, drug allergy, tetanus status
- PEx: VA first, pupil size and reaction, EOM (diplopia), external and slit-lamp exam, ophthalmoscopy
  - if VA normal or slightly reduced: globe less likely to be perforated
  - if VA reduced: possible globe perforation, corneal abrasion, lens dislocation, retinal tear
- bone fractures
  - blow out fracture: restricted EOM, diplopia, enophthalmos (sunken eye)
  - ethmoid fracture: subcutaneous emphysema (air) of lid

- lids: swelling, laceration, emphysema
- conjunctiva: subconjunctival hemorrhage
- cornea: abrasion (detect with fluorescein staining and cobalt blue filter using slit-lamp or ophthalmoscope)
- anterior chamber: assess depth, hyphema, hypopyon
- iris: prolapse, iritis
- lens: cataract, dislocation
- vitreous: hemorrhage
- retina: tear, detachment

Refer if You Observe Any of These Signs
- Decreased VA
- Shallow anterior chamber
- Hyphema
- Abnormal pupil
- Ocular misalignment
- Retinal damage

Penetrating Trauma

- includes: ruptured globe ± lid laceration, prolapsed iris, intraocular foreign body
- rule out intraocular foreign body with CT orbit, especially if history of "metal striking metal"
- **OCULAR EMERGENCY**: initial management - REFER IMMEDIATELY
  - ABCs
  - avoid pressing on eye globe
  - avoid checking IOP
  - check vision, diplopia
  - apply rigid eye shield to protect from further trauma
  - keep head elevated 30-45° to keep IOP down
  - keep NPO
  - check tetanus status
  - give IV antibiotics
    - selecting appropriate agents depends on the mechanism of injury; Gram-positive bacteria are more commonly involved than Gram-negative; retained intraocular foreign objects increase the risk of infections with *Bacillus* species, whereas exposure to vegetable matter increase the risk of a fungal etiology

Management of Suspected Globe Rupture

CAN'T forget
CT orbits
Ancef (cefazolin) ± Aminoglycoside IV
NPO
Tetanus status

Post-Traumatic Infectious Endophthalmitis
Surv Ophthalmol 2011;56:214-251
- •Delayed primary repair (>24 h after open globe injury) increases risk for post-traumatic endophthalmitis in the absence of an intraocular foreign body (IOFB)
- If IOFB present, early vitrectomy and IOFB removal must be performed within 24 h of injury
- Extreme pain with hypopyon and vitritis indicate endophthalmitis until proven otherwise, and samples must be obtained for culture
- Treat with empirical intravitreal and intravenous antibiotic guided by nature of trauma, and adjust based on culture

Hyphema

Definition
- blood in anterior chamber, often due to damage to root of the iris
- may occur with blunt trauma

Treatment
- refer to ophthalmology
- shield and bedrest for 5 d or as determined by ophthalmologist
- sleep with head upright
- may need surgical drainage if hyphema persists or if re-bleed

Complications
- risk of re-bleed highest on day 2-5, and may result in secondary glaucoma, corneal staining, and iris necrosis
- never prescribe Aspirin® (increases risk of re-bleed)

Shaken Baby Syndrome
Syndrome of findings characterized by absence of external signs of abuse with respiratory arrest, seizures, or coma. Ocular exam findings are important diagnostically for Shaken Baby Syndrome. These findings include extensive retinal and vitreous hemorrhages that occur during the shaking process and are extremely rare in accidental trauma. A detailed fundoscopic exam or an ophthalmology referral should be conducted for all infants in whom abuse is suspected.

Blow-Out Fracture

- see Plastic Surgery, PL34

Definition
- blunt trauma causing fracture of orbital floor and herniation of orbital contents into maxillary sinus
- orbital rim remains intact
- inferior rectus and/or inferior oblique muscles may be incarcerated at fracture site
- infraorbital nerve courses along the floor of the orbit and may be damaged

Clinical Features
- pain and nausea at time of injury
- diplopia, restriction of EOM
- infraorbital and upper lip paresthesia or anesthesia (CN V2)
- enophthalmos (sunken eye) and periorbital ecchymosis

Classic Signs of Blow-Out Fracture
- Enophthalmos
- Decreased upgaze (inferior rectus trapped)
- Cheek anesthetized (infraorbital nerve trapped)

Investigations
- CT: anteroposterior and coronal view of orbits

Treatment
- avoid coughing, blowing nose, and Valsalva maneuvers
- systemic antibiotics may be indicated
- surgery if fracture >50% orbital floor, diplopia not improving, or enophthalmos >2 mm
- may delay surgery if the diplopia improves

Chemical Burns

- alkali burns have a worse prognosis than acid burns because acids coagulate tissue and inhibit further corneal penetration
- poor prognosis if cornea opaque, likely irreversible stromal damage
- even with a clear cornea initially, alkali burns can progress for weeks – thus, very guarded prognosis

Treatment

- immediately irrigate with water or balanced saline solution (BSS)
  - irrigate with eyelids retracted in emergency department with IV drip to physiologic pH (test with litmus paper)
  - swab upper and lower fornices to remove possible particulate matter
- do not attempt to neutralize an acid with a base, or vice versa
- topical antibiotics and patching
- topical cycloplegics to decrease iris spasm (pain) and prevent secondary glaucoma (due to posterior synechiae formation)
- topical steroids (prescribed by ophthalmologist) to decrease inflammation, use for <2 wk in the case of a persistent epithelial defect

Ocular Drug Toxicity

Table 12. Drugs with Ocular Toxicity

Drugs	
Amiodarone	Corneal microdeposits and superficial keratopathy (vortex keratopathy) Rare: ischemic optic neuropathy
Atropine, benztropine	Pupillary dilation (risk of angle-closure glaucoma)
Bisphosphonates (Fosamax®, Actonel®)	Inflammatory eye disease (iritis, scleritis, episcleritis)
Chloroquine, hydroxychloroquine	Bull's eye maculopathy Vortex keratopathy
Chlorpromazine	Anterior subcapsular cataract
Contraceptive pills	Decreased tolerance to contact lenses Migraine Optic neuritis Retinal vein occlusion Benign increase in ICP
Digitalis	Yellow vision Blurred vision
Ethambutol	Optic neuropathy
Haloperidol (Haldol®)	Oculogyric crises Blurred vision
Indomethacin	Superficial keratopathy
Interferon	Retinal hemorrhages and cotton wool spots
Isoniazid	Optic neuropathy
Nalidixic acid	Papilledema
Steroids	Posterior subcapsular cataract Glaucoma Papilledema (systemic steroids) Increased severity of HSV infections (geographic ulcers) Predisposition to fungal infections
Sulfonamides, NSAIDs	Stevens-Johnson syndrome
Tamsulosin (Flomax®)	Intraoperative floppy iris syndrome (can complicate cataract surgery)
Tetracycline	Papilledema (associated with pseudotumour cerebri)
Thioridazine	Pigmentary degeneration of retina
Vigabatrin	Retinal deposition with macular sparing, peripheral visual field loss
Vitamin A toxicity	Papilledema
Vitamin D toxicity	Band keratopathy

Common Medications

TOPICAL OCULAR DIAGNOSTIC DRUGS

Fluorescein Dye
- water-soluble orange-yellow dye
- green under cobalt blue light (ophthalmoscope, slit-lamp ± applanation tonometry)
- absorbed in areas of epithelial loss (ulcer, abrasion, laceration)
- stains mucus, contact lenses, foreign bodies

Rose Bengal Stain
- stains devitalized epithelial cells and mucus to indicate tear film abnormalities (e.g. mucin deficiency)

Anesthetics
- e.g. proparacaine HCl 0.5%, tetracaine 0.5%
- indications: removal of foreign body and sutures, tonometry, and examination of painful cornea
- toxic to corneal epithelium (inhibit mitosis and migration) and can lead to corneal ulceration and scarring with prolonged use, therefore NEVER prescribe

Mydriatics
- dilate pupils
- two classes
  - cholinergic blocking (e.g. tropicamide – Mydriacyl®)
    - dilation plus cycloplegia (loss of accommodation) by paralysis of iris sphincter and the ciliary body
    - indications: refraction, ophthalmoscopy, therapy for iritis
  - adrenergic stimulating (e.g. phenylephrine HCl 2.5%)
    - stimulate pupillary dilator muscles, no effect on accommodation
    - usually used with tropicamide for additive effects
    - side effects: HTN, tachycardia, arrhythmias

Table 13. Mydriatic Cycloplegic Drugs and Duration of Action

Drugs	Duration of Action
Tropicamide (Mydriacyl®) 0.5%, 1%	4-5 h
Cyclopentolate HCl 0.5%, 1%	3-6 h
Homatropine HBr 1%, 2%	3-7 d
Atropine sulfate 0.5%, 1%	1-2 wk
Scopolamine HBr 0.25%, 5%	1-2 wk

Ophthalmic Drop Cap Colours

Green	Cholinergics
Red	Anticholinergics
White	Anesthetics, antibiotics, artificial tears, steroids
Yellow	β-blockers
Blue	β-blocker combinations
Purple	α-agonists
Teal	Prostaglandins
Orange	Carbonic anhydrase inhibitors
Tan	Fluoroquinolones
Grey	NSAIDs
Pink	Anti-inflammatories, steroids

GLAUCOMA MEDICATIONS

Table 14. Glaucoma Medications

Drug Category	Dose	Effect	Comment/Side Effects
α-Agonist **α2-selective** • brimonidine 0.2% (Alphagan®) • apraclonidine 0.5% (Iopidine®)	1 gtt OS/OD BID/TID	Non-selective: reduced aqueous production + increased TM outflow Selective: reduced aqueous production + increased uveoscleral outflow	Non-selective: mydriasis, macular edema, tachycardia Selective: contact allergy, hypotension/apnea in children
β-Blocker Non-selective • timolol (Timoptic®) • levobunolol (Betagan®) **β 1-selective** • betaxolol (Betoptic®)	1 gtt OS/OD once daily/BID	Reduced aqueous production	**Bronchospasm (caution in asthma/COPD)** Increased CHF Bradycardia, hypotension, depression, heart block, impotence
Carbonic Anhydrase Inhibitor • dorzolamide (Trusopt®) • brinzolamide (Azopt®) • oral: acetazolamide (Diamox®), methazolamide (Neptazane®)	1 gtt OS/OD TID Diamox®: 500 mg PO BID	Reduced aqueous production	**Must ask about sulfa allergy** Generally local side effects with topical preparations Oral: diuresis, fatigue, paresthesia, GI upset
Parasympathomimetic (cholinergic stimulating) • pilocarpine (Pilopine®) • carbachol (Isopto Carbachol®)	1-2 gtts OS/OD TID/QID	Increased TM outflow	Miosis Reduced night vision Increased GI motility, brow ache, headache Reduced heart rate
Prostaglandin Analogues • latanoprost (Xalatan®) • •travaprost (Travatan®) • bimatoprost (Lumigan®)	1 gtt OS/OD QHS	Increased uveoscleral outflow (uveoscleral responsible for 20% of drainage)	Iris colour change Periorbital skin pigmentation Lash growth Conjunctival hyperemia

Cosopt® = timolol + dorzolamide; Xalacom® = timolol + lantanoprost; Combigan® = timolol + brimonidine; DuoTrav® = timolol + travaprost; gtt = drop, gtts = drops

WET AGE-RELATED MACULAR DEGENERATION MEDICATIONS

VEGF Inhibitors (Anti-VEGF)
- anti-VEGF agents prevent ocular angiogenesis and development of choroidal neovascularization
- administered via intravitreal injections
- aflibercept (Eylea®) is a VEGF "trap" agent that binds VEGF-A, B, and placental growth factor
- ranibizumab (Lucentis®) is a monoclonal Fab fragment and non-selective anti-VEGF agent
- bevacizumab (Avastin®) is recombinant humanized monoclonal IgG antibody and non-selective anti-VEGF agent
  - FDA-approved only for treatment of metastatic breast cancer, colorectal cancer, and non-small cell lung cancer; therefore, its widespread ophthalmologic use is off-label

Intravitreal Bevacizumab vs. Ranibizumab for Treatment of Neovascular Age-Related Macular Degeneration: Findings from a Cochrane Systematic Review
Ophthalmology 2016; 123(1):70-77
Summary: In 6 RCTs with 2809 participants, there were no important differences in effectiveness or safety between bevacizumab and ranibizumab, despite a significant cost difference.

Antiplatelet and Anticoagulant Drugs Do Not Affect Visual Outcome in Neovascular Age-Related Macular Degeneration in the BRAMD Trial
Am J Ophthalmol 2018;187:130-137
Summary: In 330 NVAMD patients receiving either bevacizumab or ranibizumab treatment, use of anti-coagulant and anti-platelet agents was not associated with visual decline or occurrence of ocular hemorrhages.

TOPICAL OCULAR THERAPEUTIC DRUGS

NSAIDs
- used for less serious chronic inflammatory conditions
- e.g. ketorolac (Acular®), diclofenac (Voltaren®), nepafenac (Nevanac®) drops

Anti-Histamines
- used to relieve red and itchy eyes, often in combination with decongestants
- sodium cromoglycate – stabilizes membranes
- olopatadine (Patanol®, Pataday®)

Decongestants
- weak adrenergic stimulating drugs (vasoconstrictor)
- e.g. naphazoline, phenylephrine (Isopto Frin®)
- rebound vasodilation with overuse; rarely can precipitate angle-closure glaucoma

Antibiotics
- indications: bacterial and hyperpurulent conjunctivitis, corneal abrasions and ulcers, endophthalmitis, keratitis, blepharitis, globe rupture, cellulitis, lacrimal sac, and lacrimal gland infections
- commonly as topical drops or ointments, may give systemically
- e.g. sulfonamide (sodium sulfacetamide, sulfisoxazole), aminoglycosides (gentamicin (Garamycin®), tobramycin (Tobrex®)), erythromycin, tetracycline, bacitracin, polymyxin B, fluoroquinolones (ciprofloxacin (Ciloxan®), ofloxacin (Ocuflox®), moxifloxacin (Vigamox®), gatifloxacin (Zymar®))

Corticosteroids
- e.g. fluorometholone (FML®), betamethasone, dexamethasone (Maxidex®), prednisolone (Predsol® 0.5%, Pred Forte® 1%), rimexolone (Vexol®), loteprednol etabonate 0.5% (Lotamax®), and difluprednate (Durezol®)
- primary care physicians should avoid prescribing topical corticosteroids due to risk of glaucoma, cataracts, and reactivation of HSV keratitis
- complications
  - potentiates HSV keratitis and fungal keratitis as well as masking symptoms
  - increased IOP, more rapidly in steroid responders (within weeks)
  - posterior subcapsular cataract (within months)

Landmark Ophthalmology Trials

Trial Name	Reference	Clinical Trial Details
AGE-RELATED MACULAR DEGENERATION		
AREDS2	JAMA 2013;309(19):2005-2015	**Title**: Lutein + Zeaxanthin and Omega-3 Fatty Acids for AMD: The Age-Related Eye Disease Study 2 (AREDS2) Randomized Clinical Trial **Purpose**: To determine whether adding lutein + zeaxanthin, DHA + EPA, or both to the AREDS formulation (vitamins C and E, β-carotene, zinc, and copper) decreases the risk of developing advanced AMD and to evaluate the effect of eliminating β-carotene, lowering zinc doses, or both in the AREDS formulation. Methods: Patients at risk for progression to advanced AMD were randomized to receive lutein + zeaxanthin, DHA + EPA, lutein + zeaxanthin and DHA + EPA, or placebo, in addition to taking the AREDS formula. **Results**: Comparison with placebo (AREDS formula alone) in the primary analyses demonstrated no statistically significant reduction in progression to advanced AMD. There was no apparent effect of β-carotene elimination or lower-dose zinc on progression to advanced AMD. More lung cancers were noted in the β-carotene, mostly in former smokers. **Conclusions**: Addition of lutein+zeaxanthin, DHA+EPA, or both to the AREDS formulation did not further reduce risk of progression to advanced AMD. Because of the potential increased incidence of lung cancer with high doses of β-carotene, lutein+zeaxanthin could be an appropriate carotenoid substitute in the AREDS formulation.
CATT	NEJM 2011;364(20):1897-908	**Title**: Ranibizumab and Bevacizumab for Neovascular Age-Related Macular Degeneration **Purpose**: To assess the efficacy and safety of ranibizumab and bevacizumab and to determine whether an as-needed regimen would compromise long-term VA, as compared with a monthly regimen **Methods**: Patients with neovascular AMD where randomized to receive intravitreal injections of ranibizumab or bevacizumab on either a monthly schedule or as needed with monthly evaluation. The primary outcome was the mean change in VA at 1 year. **Results**: Bevacizumab was equivalent to ranibizumab whether it was administered monthly or as needed. Ranibizumab as needed was equivalent to monthly ranibizumab, but the comparison of bevacizumab as needed and monthly was inconclusive. The mean decrease in central retinal thickness was greater in the ranibizumab-monthly group than in the other groups. The rates of death, myocardial infarction, and stroke were not statistically different. **Conclusions**: Bevacizumab and ranibizumab had equivalent effects on VA at 1 yr when administered according to the same schedule. There was no difference between ranibizumab given as needed and ranibizumab given monthly.
GLAUCOMA		
OHTS	Arch Ophthalmol 2002;120(6):701-13	**Title**: The Ocular Hypertension Treatment Study: a randomized trial determines that topical ocular hypotensive medication delays or prevents the onset of primary open-angle glaucoma **Purpose**: To determine the safety and efficacy of topical ocular hypotensive medication in delaying or preventing the onset of POAG. **Methods**: 1636 patients with no evidence of glaucomatous damage and with IOP between 24-32 mmHg in one eye and between 21-32 mmHg in the other eye were randomized to observation or to treatment with commercially available topical ocular hypotensive medication. The primary outcome was development of visual field abnormality or optic disc deterioration attributed to POAG. **Results**: Mean reduction in IOP in the medication group was 22.5%±9.9% vs. 4.0%±11.6% in the observation group. At 5 years, the probability of developing POAG was 4.4% in the medication group and 9.5% in the observation group ($P<0.0001$). **Conclusions**: Topical ocular hypotensive medication was effective in delaying or preventing the onset of POAG in individuals with elevated IOP.
UKGTS	Lancet 2015;385(9975):1295-304	**Title**: Latanoprost for open-angle glaucoma (UKGTS): a randomised, multicentre, placebo-controlled trial **Purpose**: To assess vision preservation in patients given latanoprost compared with those given placebo. **Methods**: Patients with newly diagnosed POAG were randomized to receive either latanoprost 0.005% or placebo eye drops. The primary outcome was time to visual field deterioration within 24 months. **Results**: At 24 months, mean reduction in IOP was 3.8 mmHg in 231 patients assessed in the latanoprost group and 0.9 mmHg in 230 patients assessed in the placebo group. Visual field preservation was significantly longer in the latanoprost group than in the placebo group. **Conclusions**: There is preservation of the visual field with an intraocular-pressure-lowering drug, latanoprost, in patients with POAG.

Trial Name	Reference	Clinical Trial Details
DIABETIC RETINOPATHY		
Effects of Medical Therapies on Retinopathy Progression in T2DM	NEJM 2010;363:233-244	**Title**: Effects of Medical Therapies on Retinopathy Progression in T2DM **Purpose**: To determine whether intensive glycemic control, combination therapy for dyslipidemia, and intensive blood pressure control can limit the progression of DR in persons with T2DM. **Methods**: Participants with T2DM at high-risk of cardiovascular disease were randomized to receive either intensive or standard treatment for glycemia, dyslipidemia, or systolic blood-pressure control. Participants were evaluated for the effect of these interventions on the progression of DR. **Results**: Rates of progression of DR at 4 yr were 7.3% with intensive glycemia treatment vs. 10.4% with standard therapy; 6.5% with fenofibrate for intensive dyslipidemia therapy vs. 10.2% with placebo and 10.4% with intensive blood pressure therapy vs. 8.8% with standard therapy. **Conclusions**: Intensive glycemic control and intensive combination treatment of dyslipidemia, but not intensive blood pressure control, reduced the rate of DR.
UKPDS 69	Arch Ophthalmol 2004;122(11):1631-40	**Title**: Risks of progression of retinopathy and vision loss related to tight blood pressure control in type 2 diabetes mellitus: UKPDS 69 **Purpose**: To determine the relationship between tight BP control and the different aspects of DR in patients with T2DM. **Methods**: 758 patients were allocated to a tight BP control policy (<150/85) with angiotensin-converting enzyme inhibitor or beta-blockers as the main therapy; 390 were allocated to a less tight BP control policy (<180/105). **Results**: There was a significantly higher microaneurysm count, hard exudates prevalence, and cotton-wool spots in the tight BP control group compared to the less tight BP control group. Patients with tight BP control were less likely to undergo photocoagulation. The cumulative incidence of the end point of blindness in 1 eye was 18/758 for the tight BP control group compared with 12/390 for the less tight BP control group. **Conclusions**: High BP is detrimental to each aspect of diabetic retinopathy; a tight BP control policy reduces the risk of clinical complications from diabetic eye disease.
EDTRS 9	Ophthalmology 1991;98:766-85	**Title**: Early photocoagulation for diabetic retinopathy. ETDRS report number 9. Early Treatment Diabetic Retinopathy Study Research Group **Purpose**: To evaluate the efficacy of argon laser photocoagulation in deterring the progression of early DR into more advanced DR, as well as best time to initiate treatment. **Methods**: For patients with mild-to-severe non-proliferative or early proliferative DR in both eyes, one eye of each patient was assigned randomly to early photocoagulation and the other to deferral of photocoagulation (initiated as soon as high-risk proliferative retinopathy was detected). Eyes selected for early photocoagulation received one of four different combinations of scatter and focal treatment. **Results**: Early treatment was associated with a small reduction in the incidence of severe visual loss compared with deferral of photocoagulation, but 5-year rates were low in both the early treatment and deferral groups (2.6% and 3.7%). Adverse effects of scatter photocoagulation on visual acuity and visual field also were observed. **Conclusions**: Scatter photocoagulation is not recommended for eyes with mild or moderate nonproliferative diabetic retinopathy but is for more severe disease and should not be delayed. Focal photocoagulation is recommended for eyes with macular edema, as it reduces the risk of visual loss.

Fractures – General Principles

Fracture Description

1. Name of Injured Bone

2. Integrity of Skin/Soft Tissue
- closed: skin/soft tissue over and near fracture is intact
- open: skin/soft tissue over and near fracture is lacerated or abraded, such that fracture site can communicate with contaminants (i.e. outside environment or bowel)
- signs: continuous bleeding from puncture site, or fat droplets in blood are suggestive of an open fracture

3. Location
- epiphyseal: end of bone, forming part of the adjacent joint
- metaphyseal: the flared portion of the bone at the ends of the shaft
- diaphyseal: the shaft of a long bone (proximal, middle, distal)
- physis: growth plate

4. Orientation/Fracture Pattern (see Figure 4, OR6)
- transverse: fracture line perpendicular (<30° of angulation) to long axis of bone; result of direct high energy force
- oblique: angular fracture line (30°-60° of angulation); result of angulation and compressive force, high energy
- butterfly: triangular or wedge-shaped fragment resembling a butterfly; commonly between the two main fracture fragments in comminuted long bone fractures
- segmental: a separate segment of bone bordered by fracture lines; often the result of high-energy force
- spiral: complex, multi-planar fracture line; result of rotational force, low energy
- comminuted/multi-fragmentary: >2 fracture fragments
- intra-articular: fracture line crosses articular cartilage and enters joint
- compression: impaction of bone; typical sites are vertebrae or proximal tibia
- torus: compression of bony cortex on one side while the other remains intact, often seen in children (see Figure 50, OR45)
- greenstick: compression of one side with fracture of the opposite cortex, often seen in children (see Figure 50, OR45)
- pathologic: fracture through abnormal bone weakened by disease (e.g. tumour)

Displacement
Refers to position of the distal fragment relative to the proximal fragment

Varus/Valgus Angulation
Refers to the distal segment of the bone compared to the proximal segment
Varus = Apex away from midline
Valgus = Apex toward midline

Quick Upper Extremity Motor Nerve Exam
"Thumbs Up": PIN (Radial Nerve)
"OK Sign": AIN (Median Nerve)
"Spread Fingers": Ulnar Nerve

X-Ray Rule of 2s
2 sides = bilateral
2 views = AP + lateral
2 joints = joint above + below
2 times = before + after reduction

Sample Fracture Description
Closed (overlying skin integrity) spiral fracture (fracture pattern) of the distal third (location) of the left tibia (injured bone), with mild varus angulation, lateral translation and angulation (alignment of fracture fragments). The fracture does not extend to the joint surface

5. Alignment of Fracture Fragments (see Figure 5)

- non-displaced: fracture fragments are in anatomic alignment
- displaced: fracture fragments are not in anatomic alignment
- distracted: fracture fragments are separated by a gap (opposite of compression)
- translated: percentage of overlapping bone at fracture site
- angulated: direction of fracture apex (e.g. varus/valgus)
- rotated: fracture fragment rotated about long axis of bone
- shortened: fracture fragments are compressed, resulting in shortened bone
- avulsion: tendon or ligament tears/pulls off bone fragment

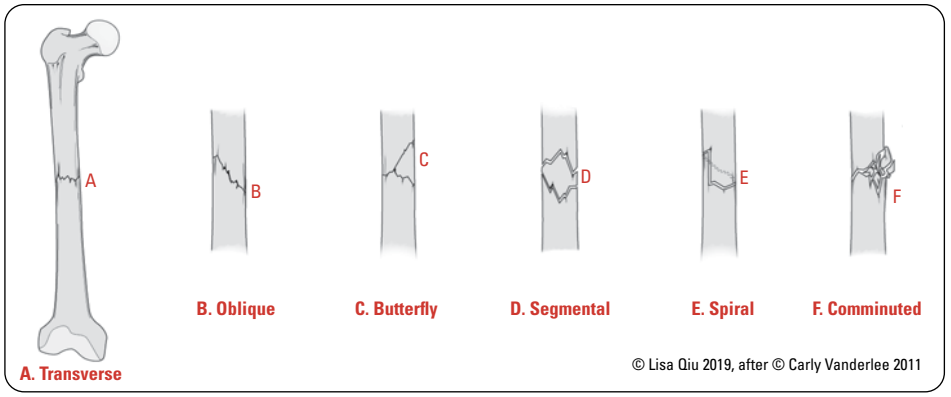

Figure 4. Orientation/fracture pattern

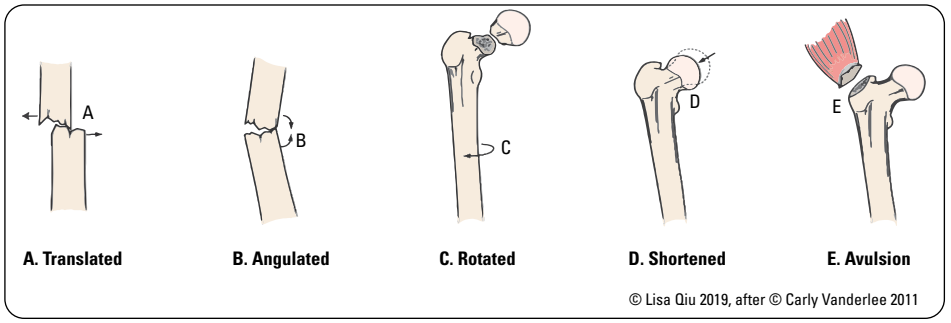

Figure 5. Alignment of fracture fragments

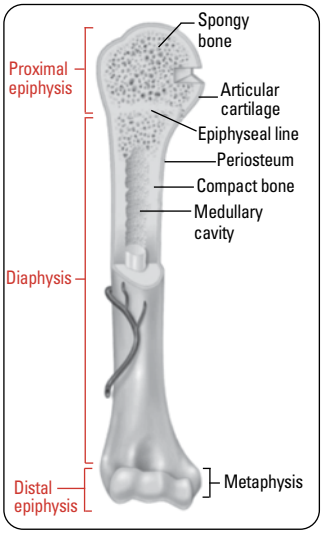

Figure 6. Schematic diagram of the long bone

Approach to Fractures

1. Clinical Assessment

- ABCs, primary survey, and secondary survey (ATLS protocol)
  - assess for life threatening injury and other fractures
  - assess for open fracture
- AMPLE- F history (minimum): Allergies, Medications, Past medical history, Last meal, Events (mechanism of injury), Function pre-injury
  - previous significant injury or surgery to affected area
  - consider pathologic fracture with history of only minor trauma
- physical exam: inspect (deformity, soft tissue integrity); palpate (maximal tenderness, NVS- document best possible neurovascular exam, avoid ROM/moving injured area to prevent exacerbation)

2. Analgesia

- oral, IV, or local (e.g. hematoma block)

3. Imaging (see *Orthopaedic X-Ray Imaging*, OR8)

4. Reduction: closed vs. open

- closed reduction (with IV sedation and muscle relaxation if necessary)
  - apply traction in the long axis of the limb
  - reverse the mechanism that produced the fracture
- open reduction
  - "NO CAST" (see sidebar)
  - other indications include
    - failed closed reduction
    - unable to cast or apply traction due to site
    - pathologic fractures
    - potential for improved function and/or outcomes with ORIF
- ALWAYS re-check and document NVS after reduction and obtain post-reduction x-ray

Reasons for Closed Reduction and Splinting

- Pain control
- Reduces further damage to vessels, nerves, and skin and may improve neurovascular status
- Reduces point loading on articular surfaces
- Decreases risk of inadvertently converting closed to open fracture
- Facilitates patient transport

Indications for Open Reduction

NO CAST
Non-union
Open fracture
Neurovascular Compromise
Displaced intra-Articular fracture
Salter-Harris 3,4,5
PolyTrauma

5. Immobilization
- external stabilization: splints, casts, traction, external fixator
- internal stabilization: percutaneous pinning, extramedullary fixation (screws, plates, wires), IM fixation (rods)

6. Follow-up
- evaluate stages of bone healing (see *Fracture Healing*)

7. Rehabilitation
- recommend rehabilitation when appropriate to regain function and avoid joint stiffness

Buck's Skin Traction
A system of weights, pulleys, and ropes that are attached to the end of a patient's bed exerting a longitudinal force on the distal end of a fracture, improving its length, alignment, and rotation temporarily while awaiting fixation (typically used for lower extremity fractures)

Fracture Healing

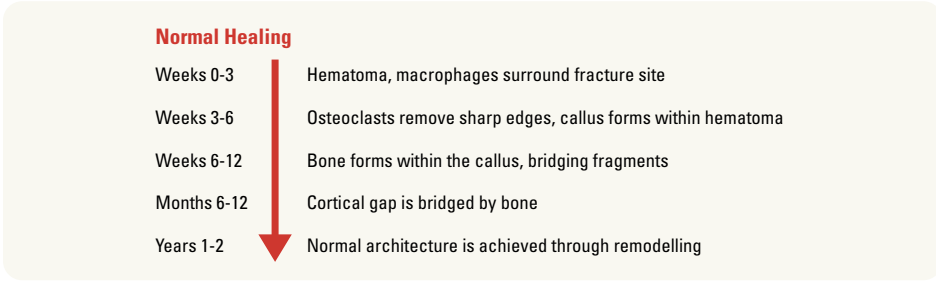

Figure 7. Stages of bone healing

Wolff's Law
Bone adapts to the amount of force applied by increasing or decreasing its mass to resist the applied stress

Evaluation of Healing: Tests of Union
- clinical: no longer tender to palpation, no mobility, minimal or no deformity on physical exam
- x-ray: trabeculae cross fracture site, visible callus bridging site on at least 3 of 4 cortices

General Fracture Complications

Table 3. General Fracture Complications

	Early	Late
Local	Compartment syndrome Neurological injury Vascular injury Infection Implant failure Fracture blisters	Mal-/non-union AVN Osteomyelitis Heterotopic ossification Post-traumatic OA Joint stiffness/adhesive capsulitis CRPS type I/RSD
Systemic	Sepsis DVT PE ARDS secondary to fat embolism Hemorrhagic shock	

Fracture Blister
Formation of vesicles or bullae that occur on edematous skin overlying a fractured bone

Heterotopic Ossification
The formation of bone in abnormal locations (e.g. in muscle), secondary to pathology

CRPS/RSD
Sustained sympathetic activity characterized by pain out of proportion to physical exam findings; symptoms of hyperalgesia and allodynia, and signs of autonomic dysfunction (temperature asymmetry, mottling, hair or nail changes)

Articular Cartilage

Properties
- hyaline cartilage
- 2-4 mm layer covering ends of articulating bones, provides nearly frictionless surface
- avascular (nutrition from synovial fluid), aneural, alymphatic

ARTICULAR CARTILAGE DEFECTS

Etiology
- overt trauma, repetitive minor trauma (such as repetitive ankle sprains or patellar maltracking)
- degenerative conditions such as early stage OA or osteochondritis dissecans

Clinical Features
- part of OA presentation: pain with movement, decreased range of motion, joint line pain with possible effusion
- have predisposing factors such as: ligament injury; malalignment of the joint (e.g. varus or valgus); obesity; AVN; and inflammatory arthropathy
- may have symptoms of locking or catching related to the torn/displaced cartilage

Investigations
- x-ray (to rule out bony defects and check alignment)
- MRI (if x-ray is normal; MRI is not needed to assess cartilage loss associated with osteoarthritis)

Avascular Necrosis
Ischemia of bone due to disrupted blood supply; most commonly affecting the femoral head, talus, or proximal scaphoid

Osteochondritis Dissecans
Avascular necrosis of subchondral bone most often occurring in children and adolescents and causing pain and potentially hindering joint motion

Table 4. Outerbridge Classification of Chondral Defects

Grade	Chondral Damage
I	Softening and swelling of cartilage
II	Fragmentation and fissuring <1/2" in diameter
III	Fragmentation and fissuring >1/2" in diameter
IV	Erosion of cartilage down to bone

Treatment

- individualized
  - patient factors (age, skeletal maturity, activity level, etc.)
  - defect factors (Outerbridge Classification, subchondral bone involvement, etc.)
- non-operative
  - rest, COX2 inhibitors, NSAIDs, bracing, physiotherapy, intra-articular corticosteroids
- operative
  - microfracture, osteochondral grafting (autograft or allograft), autologous chondrocyte implantation

Orthopaedic X-Ray Imaging

General Principles - "Rule of 2s"

- x-ray 1 joint above and 1 below
- obtain at least 2 orthogonal views ± specialized views
- 2 sides, as needed for comparison

When reading a radiograph consider

- open or closed fracture (air/gas seen in the soft tissue)
- the view
- anatomical location
- laterality (right vs. left)
- skeletally mature vs. immature
- intra-articular vs. extra-articular
- joint congruent, subluxed or dislocated
- rotation
- angulation
- displacement
- shortening

Table 5. Orthopaedic X-Ray Imaging

Site	Injury	X-Ray Views
Shoulder	Anterior dislocation Posterior dislocation AC separation	AP Axillary ± stress view with 10 lb in hand Trans-scapular Zanca view (10-15 cephalic tilt)
Arm	Humerus #	AP Lateral
Elbow/Forearm	Supracondylar # Radial head # Monteggia # Nightstick # Galeazzi #	AP Lateral
Wrist	Colles' # Smith # Scaphoid #	AP Lateral Clenched Fist (for scapholunate dissociation)
Pelvis	Pelvic #	AP pelvis Inlet and outlet views Judet views (obturator and iliac oblique for acetabular #)
Hip	Femoral head/neck # Intertrochanteric # Arthritis SCFE FAI Developmental dysplasia of the hip (DDH)	AP Lateral Frog-leg lateral Dunn False profile
Knee	Knee dislocation Femur/tibia # Patella # Patella dislocation Patella femoral syndrome	AP standing, lateral Skyline (tangential view with knees flexed at 45° to see patellofemoral joint)
Leg	Tibia shaft # Fibula shaft #	AP Lateral

Table 5. Orthopaedic X-Ray Imaging

Site	Injury	X-Ray Views
Ankle	Ankle #	AP Lateral Mortise view (ankle at 15° of internal rotation)
Foot	Talar # Calcaneal # MT # Lisfranc injuries	AP Lateral Oblique Lateral, Harris, axial
Spine	Compression # Burst # Cervical spine #	AP spine AP odontoid Lateral Oblique Swimmer's view (lateral view with arm abducted 180° to evaluate C7-T1 junction if lateral view is inadequate) Lateral flexion/extension view: evaluate subluxation of cervical vertebrae

Orthopaedic Emergencies

Trauma Patient Workup

Etiology
- high energy trauma (e.g. MVC, fall from height)
- may be associated with spinal injuries or life-threatening visceral injuries

Clinical Features
- comminuted, open fractures with significant soft tissue injury
- local swelling, tenderness, deformity of the limbs, and instability of the pelvis or spine
- decreased level of consciousness, hypotension, hypovolemia
- consider involvement of EtOH or other psychoactive substances

Investigations
- trauma survey (see Emergency Medicine, ER2)
- x-rays: lateral cervical spine, AP chest, AP pelvis, AP and lateral of all bones suspected to be injured
- CT is also utilized to inspect for musculoskeletal injuries in the trauma setting
- other views of pelvis: AP, inlet, and outlet; Judet views for acetabular fracture (see Table 19, OR30)

Treatment
- ABCDEs: initiate resuscitation for life-threatening injuries (ATLS protocol)
- assess genitourinary injury (rectal exam/vaginal exam mandatory)
- external or internal fixation of all fractures
- if patient unstable then Damage Control Orthopaedics – use of external fixation for fractures initially and then bring patient back to OR for definitive fixation (IM nail or ORIF) once hemodynamically stable
- DVT prophylaxis once stable

Complications
- hemorrhage – life-threatening (may produce signs and symptoms of hypovolemic shock)
- fat embolism syndrome – SOB, hypoxemia, petechial rash, thrombocytopenia, and neurological symptoms
- venous thromboembolism – DVT and PE
- bladder/urethral/bowel injury
- neurological damage
- persistent pain/stiffness/limp/weakness in affected extremities
- post-traumatic OA of joints with intra-articular fractures
- sepsis and/or tetanus infection especially if missed open fracture

Orthopaedic Emergencies

VON CHOP
Vascular compromise
Open fracture
Neurological compromise/cauda equina syndrome
Compartment syndrome
Hip dislocation
Osteomyelitis/septic arthritis
Unstable Pelvic fracture

Controversies in Initial Management of Open Fractures
Scand J Surg 2014;103(2):132-137
Study: Literature review examining the initial management of open fractures. 40 studies included. Findings:
- A first-generation cephalosporin (or clindamycin) should be administered upon arrival. In general, 24 h of antibiotics after each debridement is sufficient to reduce infection rates.
- Although cultures are taken from delayed (>24 h) or infected injuries, it may not be necessary to routinely take post-debridement cultures in open fractures.
- Open fractures should be debrided as soon as possible, although the "6 h rule" is not generally valid.
- Wounds should be closed within 7 d once soft tissue has stabilized and all non-viable tissue removed.
- Negative pressure wound therapy (NPWT) has been shown to decrease infection rates in open fractures.

Open Fractures

- fractured bone and hematoma in communication with the external or contaminated environment

33% of patients with open fractures have multiple injuries

Emergency Measures

- ABCs, primary survey, and resuscitate as needed
- remove obvious foreign material
- irrigate with normal saline if grossly contaminated
- cover wound with sterile dressings
- immediate IV antibiotics
- tetanus toxoid or immunoglobulin as needed (see Plastic Surgery, PL28)
- NPO and prepare for OR (blood work, consent, ECG, CXR)
  - operative irrigation and debridement within 6-8 h to decrease risk of infection
  - ORIF
  - traumatic wound may be left open to drain with vacuum-assisted closure if necessary
  - re-examine with repeat irrigation and debridement in 48 h if necessary

Antibiotic Prophylaxis in the Management of Open Fractures
JBJS Reviews: 2019 Feb;7(2):e1
Purpose: Provide current practice recommendations on prophylaxis for patients with open fractures of the extremities.
Methods: Systematic survey of publications from January 2007 to June 2017, and search of WorldCat for textbooks and websites for institutional guidelines.
Results: Most recommendations suggested Gram-positive antibiotics up to 3 d post-injury for less severe injuries. For more severe injuries, most recommendations included broad spectrum antibiotics for 2-3 d. As well, most sources recommend immediate IV administration of antibiotics.
Conclusions: Current practice recommendations support early systemic prophylaxis for patients with open fractures of the extremities. However, differences are seen across antibiotic regimens, doses, and duration of administration.

Table 6. Gustilo Classification of Open Fractures

Gustilo Grade	Length of Open Wound	Description	Prophylactic Antibiotic Regimen
I	<1 cm	Minimal contamination and soft tissue injury Simple or minimally comminuted fracture	First generation cephalosporin (cefazolin) 2 g IV q8 h for 2 d If allergy use clindamycin 900 mg IV q8 h If MRSA positive use vancomycin 15 mg/kg IV q12 h
II	1-10 cm	Moderate contamination Moderate soft tissue injury	As per Grade I
III*	>10 cm	IIIA: Extensive soft tissue injury with adequate ability of soft tissue to cover wound IIIB: Extensive soft tissue injury with periosteal stripping and bone exposure; inadequate soft tissue to cover wound IIIC: Vascular injury/compromise	First generation cephalosporin (cefazolin) for 2 d plus Gram-negative coverage (gentamicin or ceftriaxone) for at least 3 d For soil or fecal contamination, metronidazole is added for anaerobic coverage ± penicillin G If MRSA positive use vancomycin 15 mg/kg IV q12 h

*Any high energy, comminuted fracture, shot gun, farmyard/soil/water contamination, exposure to oral flora, or fracture >8 h old is immediately classified as Grade III

Cauda Equina Syndrome

- see Neurosurgery, NS32

Compartment Syndrome

- increased interstitial pressure in an anatomical compartment (forearm, calf) where muscle and tissue are bounded by fascia and bone (fibro-osseous compartment), with little room for expansion
- interstitial pressure exceeds capillary perfusion pressure, leading to irreversible muscle necrosis (in 4-6 h) and eventually nerve necrosis

Most important sign is increased pain with passive stretch. Most important symptom is pain out of proportion to injury

Etiology

- intracompartmental
  - fracture (particularly tibial shaft or paediatric supracondylar and forearm fractures)
  - reperfusion injury, crush injury, or ischemia
- extracompartmental: constrictive dressing (circumferential cast), poor position during surgery, circumferential burn

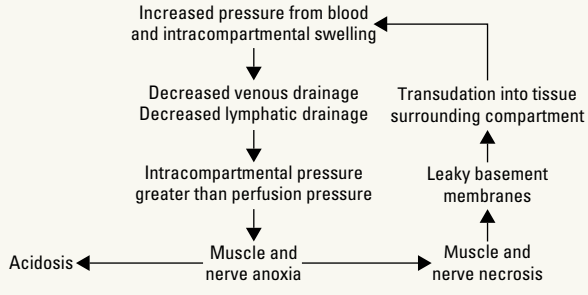

Figure 8. Pathogenesis of compartment syndrome

5 Ps of Compartment Syndrome
Pain: out of proportion for injury and not relieved by analgesics
- Increased pain with passive stretch of compartment muscles

Pallor: late finding
Paresthesia
Paralysis: late finding
Pulselessness: late finding

Clinical Features
- pain out of proportion to injury (typically first and most significant symptom)
- pain with active contraction of compartment
- pain with passive stretch (most sensitive sign)
- swollen, tense compartment
- suspicious history

- **5 Ps**: late sign – do not wait for these to develop to make the diagnosis!

Investigations
- compartment syndrome is a clinical diagnosis; investigations usually not necessary
- in children or unconscious patients where clinical exam is unreliable, compartment pressure monitoring with catheter (normal = 0 mmHg; elevated ≥30 mmHg or [dBP – measured pressure] ≤30 mmHg)

Treatment
- non-operative
  - remove constrictive dressings (casts, splints), elevate limb to the level of the heart
- operative
  - urgent fasciotomy
  - 48-72 h postoperative: necrotic tissue debridement + wound closure
  - may require delayed closure and/or skin grafting

Complications
- Volkmann's ischemic contracture: ischemic necrosis of muscle; followed by secondary fibrosis; and finally calcification - especially following supracondylar fracture of humerus
- rhabdomyolysis, renal failure secondary to myoglobinuria

Osteomyelitis

- bone infection with progressive inflammatory destruction

Etiology
- most commonly caused by *S. aureus*
- mechanism of spread: hematogenous (most common) vs. direct-inoculation vs. contiguous focus
- risk factors: recent trauma/surgery, immunocompromised patients, DM, IV drug use, poor vascular supply, peripheral neuropathy

Clinical Features
- symptoms: pain and fever
- on exam: erythema, tenderness, edema common ± abscess/draining sinus tract; impaired function/WB

Diagnosis
- see Medical Imaging, MI25 and MI29
- workup may include: WBC and differential, ESR, CRP, blood culture, aspirate culture/bone biopsy

Table 7. Treatment of Osteomyelitis

Acute Osteomyelitis	Chronic Osteomyelitis
IV antibiotics 4-6 wk; started empirically and adjusted after obtaining blood and aspirate cultures	Surgical debridement
± surgery (I&D) for abscess or significant involvement	Antibiotics: both local (e.g. antibiotic beads) and systemic (IV)
± hardware removal (if present)	

Septic Joint

- joint infection with progressive destruction if left untreated

Etiology
- most commonly caused by *S. aureus* in adults
- consider coagulase-negative *Staphylococcus* in patients with prior joint replacement
- consider *N. gonorrhoeae* in sexually active adults, and newborns
- most common route of infection is hematogenous
- risk factors: young/elderly (age >80 yr), prosthetic joint, recent joint surgery, skin infection/ulcer, IV drug use, recent intra-articular corticosteroid injection, immunocompromised (cancer, DM, alcoholism, RA)

Plain Film Findings of Osteomyelitis
- Soft tissue swelling
- Lytic bone destruction*
- Periosteal reaction (formation of new bone, especially in response to #)*

*Generally not seen on plain films until 10-12 d after onset of infection

Rapid progression of signs and symptoms (over hours) necessitates need for serial examinations

Acute osteomyelitis is a medical emergency which requires an early diagnosis and appropriate antimicrobial and surgical treatment

Most commonly affected joints in descending order
knee → hip → elbow → ankle → sternoclavicular joint

Plain Film Findings in a Septic Joint
- Early (0-3 d): usually normal; may show soft-tissue swelling or joint space widening from localized edema
- Late (4-6 d): joint space narrowing and destruction of cartilage

Serial C-reactive protein (CRP) can be used to monitor response to therapy

Does This Adult Patient Have Septic Arthritis?
JAMA 2007;297(13):1478-1488
Purpose: To review the accuracy and precision of the clinical evaluation for the diagnosis of nongonococcal bacterial arthritis.
Methods: Review of 14 studies including 6242 patients of which 653 had positive synovial culture (gold standard diagnostic tool for septic arthritis).
Results: Age, diabetes mellitus, rheumatoid arthritis, joint surgery, hip or knee prosthesis, skin infection, and human immunodeficiency virus type 1 infection significantly increase the probability of septic arthritis. Joint pain, history of joint swelling, and fever are found in >50% of cases. The presence of increased WBC increases the likelihood ratio (for counts <25000/μL: LR, 0.32; 95% CI, 0.23-0.43; for counts ≥25000/μL: LR, 2.9; 95% CI, 2.5-3.4; for counts ≥100000/μL: LR, 28.0; 95% CI, 12.0-66.0). A polymorphonuclear cell count of ≥90% increases the LR of septic arthritis by 3.4, while a PMN cell count of <90% reduces the LR by 0.34.
Conclusions: Clinical findings may be used to identify patients with monoarticular arthritis who may have septic arthritis. Laboratory findings from an arthrocentesis are also required and helpful prior to Gram stain and culture.

Clinical Features
- inability/refusal to bear weight, localized joint pain, erythema, warmth, swelling, pain on active and passive ROM, ± fever

Investigations
- x-ray (to rule out fracture, tumour, metabolic bone disease), ESR, CRP, WBC, blood cultures
- joint aspirate: cloudy yellow fluid, WBC >50000 with >90% neutrophils, protein level >4.4 mg/dL, joint glucose level <60% blood glucose level, no crystals, positive Gram stain results
- listen for heart murmur (if concern for infective endocarditis, use Duke Criteria)

Treatment
- IV antibiotics, empiric therapy (based on age and risk factors), adjust following joint aspirate C&S results
- non-operative
  - therapeutic joint aspiration, serially if necessary
- operative
  - arthroscopic or open irrigation and drainage

Shoulder

Shoulder Dislocation

- complete loss of continuity between the two articular surfaces of the glenohumeral joint; may be anterior or posterior

Investigations
- anterior disloction x-rays: AP, trans-scapular, and axillary views of the shoulder
- posterior dislocation x-rays: AP, trans-scapular, and axillary views of the shoulder; or CT scan

Table 8. Anterior and Posterior Shoulder Dislocation

	Anterior Shoulder Dislocation (>90%)	Posterior Shoulder Dislocation (5%)
MECHANISM		
	Abducted externally rotated/hyperextended arm Blow to posterior shoulder Involuntary, usually traumatic; voluntary, atraumatic	Adducted, internally rotated, flexed arm FOOSH 3 Es (epileptic seizure, EtOH, electrocution) Blow to anterior shoulder
CLINICAL FEATURES		
Symptoms	Pain, arm slightly abducted and externally rotated with inability to internally rotate	Pain, arm is held in adduction and internal rotation; external rotation is blocked
Shoulder Exam	**"Squared off" shoulder** **Positive apprehension test**: patient looks apprehensive with gentle shoulder abduction and external rotation to 90° as humeral head is pushed anteriorly and recreates feeling of anterior dislocation **Positive relocation test**: a posteriorly directed force applied during the apprehension test relieves apprehension since anterior subluxation is prevented **Positive sulcus sign**: presence of subacromial indentation with distal traction on humerus indicates inferior shoulder instability	**Anterior shoulder flattening**, prominent coracoid, palpable mass posterior to shoulder **Positive posterior apprehension ("jerk") test**: with patient supine, flex elbow 90° and adduct, internally rotate the arm while applying a posterior force to the shoulder; patient will "jerk" back with the sensation of subluxation Note: the posterior apprehension test is used to test for recurrent posterior instability, NOT for acute injury
Neurovascular Exam Including	**Axillary nerve**: sensory patch over deltoid and deltoid contraction **Musculocutaneous nerve**: sensory patch on lateral forearm and biceps contraction	Full neurovascular exam as per anterior shoulder dislocation
RADIOGRAPHIC FINDINGS		
Axillary View	Humeral head is anterior	Humeral head is posterior
Trans-scapular 'Y' View	Humeral head is anterior to the center of the "Mercedes-Benz"sign	Humeral head is posterior to center of "Mercedes-Benz" sign
AP View	Sub-coracoid lie of the humeral head is most common	Partial vacancy of glenoid fossa (vacant glenoid sign) and >6 mm space between anterior glenoid rim and humeral head (positive rim sign), humeral head may resemble a lightbulb due to internal rotation (lightbulb sign)
Hill-Sachs and Bony Bankart Lesions	**± Hill-Sachs lesion**: compression fracture of posterior humeral head due to forceful impaction of an anteriorly dislocated humeral head against the glenoid rim **± Bony Bankart lesion**: avulsion of the anterior glenoid labrum (with attached bone fragments) from the glenoid rim	**± Reverse Hill-Sachs lesion** (75% of cases): divot in anterior humeral head **± Reverse bony Bankart lesion**: avulsion of the posterior glenoid labrum from the bony glenoid rim

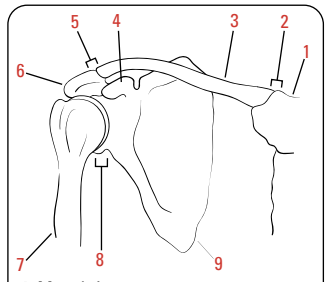
Posterior Shoulder Dislocation
Up to 60-80% are missed on initial presentation due to poor physical exam and radiographs

There are 4 Joints in the Shoulder
Glenohumeral, AC, sternoclavicular (SC), scapulothoracic

Shoulder passive ROM: abduction – 180°, adduction – 45°, flexion – 180°, extension – 45°, int. rotation – level of T4, ext. rotation – 40-45°

Factors Causing Shoulder Instability
- Shallow glenoid
- Loose capsule
- Ligamentous laxity
- Frequency of Dislocations
- Anterior shoulder > Posterior shoulder
- Posterior hip > Anterior hip

The glenohumeral joint is the most commonly dislocated joint in the body since stability is sacrificed for motion



1. Manubrium
2. Sternoclavicular joint
3. Clavicle
4. Coracoid process
5. AC joint
6. Acromion
7. Humerus
8. Glenohumeral joint
9. Scapula

Figure 10. Mercedes-Benz

Table 8. Anterior and Posterior Shoulder Dislocation

	Anterior Shoulder Dislocation (>90%)	Posterior Shoulder Dislocation (5%)
TREATMENT		
	Closed reduction with IV sedation and muscle relaxation **Traction-countertraction**: assistant stabilizes torso with a folded sheet wrapped across the chest while the surgeon applies gentle steady traction **Stimson**: while patient lies prone with arm hanging over table edge, hang a 5 lb weight on wrist for 15-20 min **Hippocratic method**: place heel into patient's axilla and apply traction to arm **Cunningham's method**: gentle longitudinal support and traction of the arm at the patient's side, massage/relaxation of deltoid, trapezius, and biceps to allow atraumatic shoulder reduction. Low-risk, low pain; if not successful try above methods Obtain post-reduction x-rays Check post-reduction NVS Sling x 3 wk (avoid abduction and external rotation), followed by shoulder rehabilitation (dynamic stabilizer strengthening)	Closed reduction with sedation and muscle relaxation Inferior traction on a flexed elbow with pressure on the back of the humeral head Obtain post-reduction x-rays Check post-reduction NVS Sling in abduction and external rotation x 3 wk, followed by shoulder rehabilitation (dynamic stabilizer strengthening)

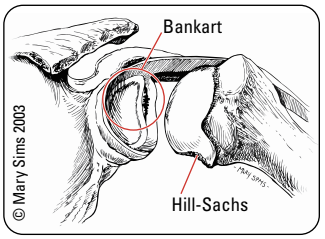

Figure 11. Posterior view of anterior dislocation causing Hill-Sachs and Bankart lesions

Prognosis

- recurrence rate depends on age of first dislocation
- <20 yr = 65-95%; 20-40 yr = 60-70%; >40 yr = 2-4%

Specific Complications

- recurrent dislocation (most common complication)
- unreduced dislocation
- shoulder stiffness
- rotator cuff or capsular or labral tear (Bankart/SLAP lesion)
- injury to axillary nerve/artery, brachial plexus

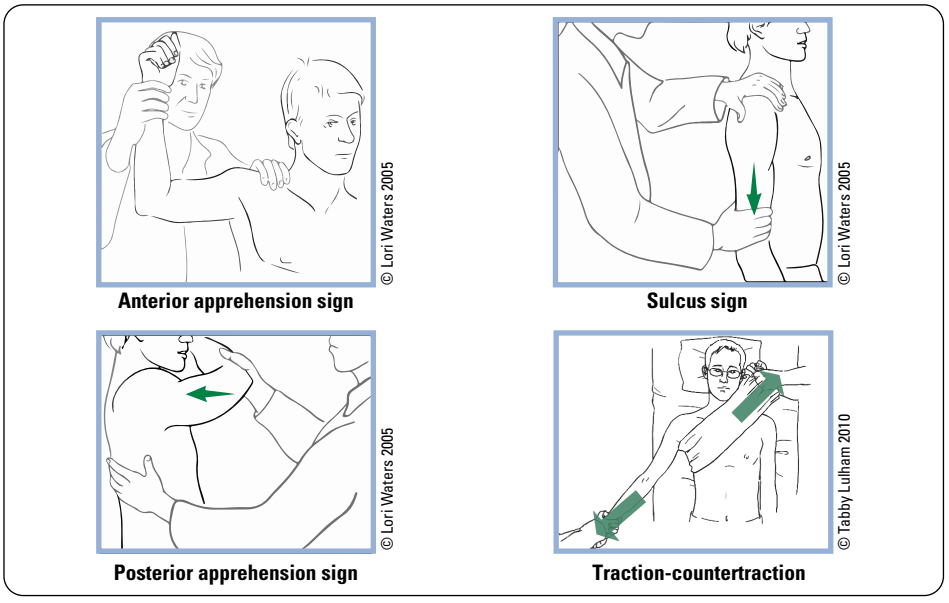

Figure 12. Shoulder maneuvers

Rotator Cuff Disease

- rotator cuff consists of 4 muscles that act to stabilize the humeral head within the glenoid fossa

Table 9. Rotator Cuff Muscles (SITS)

Muscle	Muscle Attachments		Nerve Supply	Muscle Function
	Proximal	Distal		
Supraspinatus	Scapula	Greater tuberosity of humerus	Suprascapular nerve	Abduction
Infraspinatus	Scapula	Greater tuberosity of humerus	Suprascapular nerve	External rotation
Teres Minor	Scapula	Greater tuberosity of humerus	Axillary nerve	External rotation
Subscapularis	Scapula	Lesser tuberosity of humerus	Subscapular nerve	Internal rotation and adduction

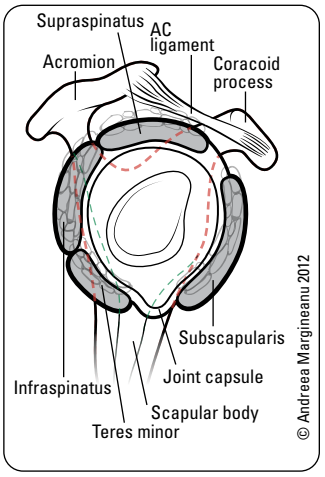

Figure 13. Muscles of the rotator cuff

SPECTRUM OF DISEASE: IMPINGEMENT, TENDONITIS, MICRO OR MACRO TEARS

Etiology

- narrowing of subacromial space
- most commonly due to a relative imbalance of rotator cuff and larger shoulder muscles, allowing for superior translation and subsequent wear of the rotator cuff muscle tendons
  - glenohumeral (rotator cuff) muscle weakness leading to abnormal motion of humeral head
  - scapular muscle weakness leading to abnormal motion of acromion – poor posture
- acromial abnormalities, such as congenital narrow space or osteophyte formation or Type III acromion morphology
  1. outlet/subacromial impingement: "painful arc syndrome," compression of rotator cuff tendons (primarily supraspinatus) and subacromial bursa between the head of the humerus and the undersurface of acromion, AC joint, and CA ligament
  2. bursitis and tendonitis
  3. rotator cuff thinning and tear if left untreated

Clinical Features

- insidious onset, but may present as an acute exacerbation of chronic disease, night pain, and difficulty sleeping on affected side
- pain worsens with active motion (especially overhead); passive movement generally permitted
- weakness and loss of ROM, especially between 90-130° (e.g. trouble with overhead activities)
- tenderness to palpation over greater tuberosity
- rule out bicep tendinosis: Speed's test; SLAP lesion: O'Brien's test

Investigations

- x-ray: AP view may show sclerosis of the undersurface of the acromion or greater tuberosity, high riding humerus relative to glenoid, indicating large tear, evidence of chronic tendonitis
- MRI: coronal/sagittal, oblique, and axial orientations are useful for assessing full/partial tears and tendinopathy ± arthrogram: geyser sign (injected dye leaks out of joint through rotator cuff tear)
- arthrogram: not commonly used but can assess full thickness tears, difficult to assess partial tears
- ultrasound: may be a useful adjunct but limited ability to evaluate other intra-articular pathology

Treatment

- non-operative
  - first line treatment, rotator cuff injury treatment begins with physiotherapy (regardless of severity on MRI findings)
  - physiotherapy, activity modification, non-narcotic analgesia ± steroid injection
  - mild or moderate cases frequently improve
  - progression to surgery if necessary
- operative
  - severe tear or impingement that is refractory to 2-3 mo physiotherapy and 1-2 corticosteroid injections
  - arthroscopic or open surgical repair (i.e. acromioplasty, rotator cuff repair)

Bigliani Classification of Acromion Morphology
- Type I – flat
- Type II – curved
- Type III – hooked

Screening Out Rotator Cuff Tears*
- No night pain (SN 87.7%)
- No painful arc (SN 97.5%)
- No impingement signs (SN 97.2%)
- No weakness

Returning to the bedside: Using the history and physical examination to identify rotator cuff tears
J Am Geriatr Soc 2000;48:1633-1637

Ruling in Rotator Cuff Tears – 98% probability of rotator cuff tear if all 3 of the following are present:
- Supraspinatus weakness
- External rotation weakness
- Positive impingement sign(s)

Diagnosis of rotator cuff tears.
Lancet 2001;357:769-770

Does this Patient with Shoulder Pain have Rotator Cuff Disease? The Rational Clinical Examination Systematic Review
JAMA 2013;310:837-847
Study: 5 studies of sufficient quality including 30-203 shoulders and a prevalence of RCD ranging from 33-81%.
Results/Conclusions: Among pain provocation tests, a positive painful arc test had the greatest specificity and sensitivity (SP 81%, SN 71%). Among strength tests, a positive external rotation lag test and internal rotation lag test were the most accurate for full-thickness tears (SP 47%, SN 94%; SP 97%, SN 83% respectively). The internal rotation lag test was therefore also the most accurate for identifying patients without a full-thickness tear.
A positive drop arm test is helpful to identify patients with RCD (SN 24%, SP 93%).

Table 10. Rotator Cuff Special Tests

Test	Examination	Positive Test
Jobe's Test (i.e. Empty Can Test)	Supraspinatus: place the shoulder in 90° of abduction and 30° of horizontal flexion (from the scapular plane) and internally rotate the arm so that the thumb is pointing toward the floor	Weakness with active resistance suggests a supraspinatus tear
Lift-off Test	Subscapularis: internally rotate arm so dorsal surface of hand rests on lower back; patient instructed to actively lift hand away from back against examiner resistance (use Belly Press Test if too painful)	Inability to actively lift hand away from back suggests a subscapularis tear
Posterior-Cuff Test	Infraspinatus and teres minor: arm positioned at patient's side in 90° of flexion; patient instructed to externally rotate arm against the resistance of the examiner	Weakness with active resistance suggests posterior cuff tear
Neer's Test	Rotator cuff impingement: passive shoulder flexion	Pain elicited between 130-170° suggests impingement
Hawkins-Kennedy Test	Rotator cuff impingement: shoulder flexion to 90° and passive internal rotation	Pain with internal rotation suggests impingement
Painful Arc Test	Rotator cuff tendinopathy: patient instructed to actively abduct the shoulder	Pain with abduction >90° suggests tendinopathy
Speed's Test	Apply resistance to the forearm when the arm is in forward flexion with the elbows fully extended	Pain in the bicipital groove
O'Brien's Test	SLAP lesion: forward flexion of the arm to 90° while keeping the arm extended. Arm is adducted 10-15° Internally rotate the arm so thumb is facing down and apply a downward force. Repeat the test with arm externally rotated	Pain or clicking in the glenohumeral joint in internal rotation but not external rotation

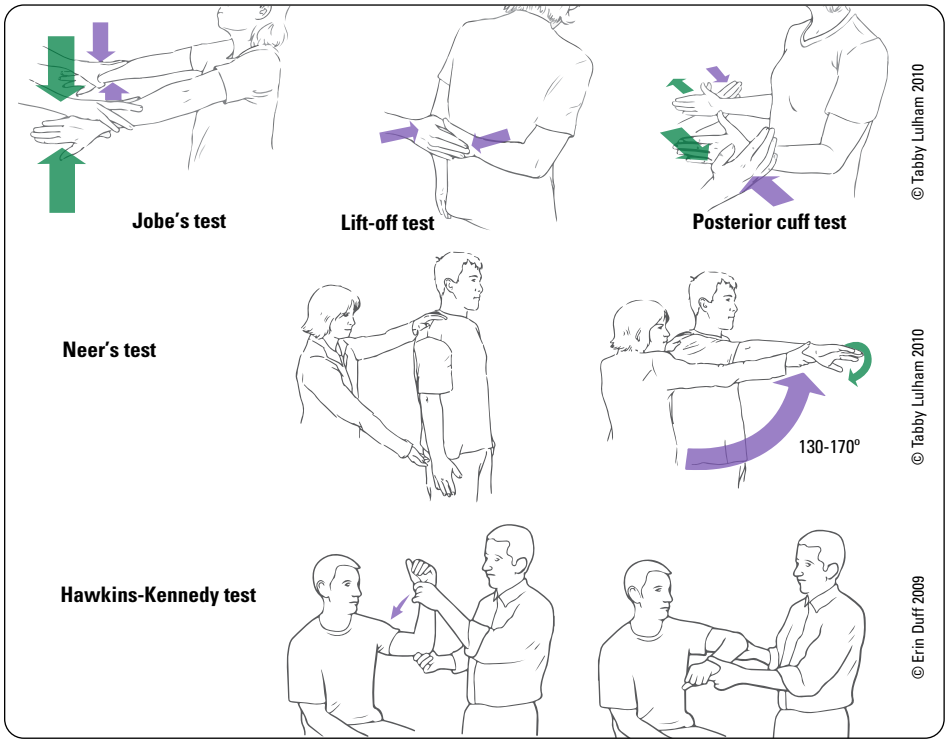

Figure 14. Rotator cuff tests

Acromioclavicular Joint Pathology

- subluxation or dislocation of AC joint
- 2 main ligament groups attach clavicle to scapula: AC and CC ligaments

Pneumothorax or pulmonary contusion are potential complications of severe clavicle fracture, and rarely severe AC joint dislocation

Mechanism
- fall onto shoulder with adducted arm or direct trauma to point of shoulder (usually fall onto the posterosuperior aspect of the lateral shoulder)

Clinical Features
- pain with adduction of shoulder and/or palpation over AC joint
- palpable step deformity between distal clavicle and acromion (with dislocation) i.e. piano key sign
- limited ROM

Investigations
- x-rays: bilateral AP, Zanca view (10-15° cephalic tilt), axillary

Treatment
- non-operative
  - sling 1-3 wk, ice, analgesia, early ROM, and rehabilitation
- operative
  - indication: Rockwood Class IV-VI (III if labourer or high level athlete)
  - number of different approaches involving AC/CC ligament reconstruction or screw/hook plate insertion

Table 11. Rockwood Classification of Acromioclavicular Joint Separation

Grade	Features	Treatment
I	Joint sprain, absence of complete tear of either ligament	Non-operative
II	Complete tear of AC ligament, incomplete tear of CC ligament, without marked elevation of lateral clavicular head	Non-operative
III	Complete tear of AC and CC ligaments, >5 mm elevation at AC joint, superior aspect of acromion is below the inferior aspect of the clavicle	Most non-operative, operative if labourer or high level athlete Will heal with step deformity, although most fully functional in 4-6 mo
IV-VI	Based on the anatomical structure the displaced clavicle is in proximity to (posterior, very superior, inferior)	Operative in most cases

Grade	AC Ligament	CC Ligament	Reducible	Treatment
I	Sprained	Normal	N/A	Non-operative
II	Torn	Sprained	Yes	Non-operative
III	Torn	Torn	Yes	Most non-operative, operative if labourer or high-level athlete Will heal with step deformity, although most fully functional in 4-6 mo
IV-VI	Torn	Torn	No	Operative in most cases

Rockwood separations IV-VI are determined based on direction of displacement:
IV: Distal clavicle displaced posteriorly into trapezius (seen on axillary XR)
V: Distal clavicle herniated through deltotrapezial fascia into subcutaneous tissue
VI: Distal clavicle displaced inferior to acromion or coracoid under conjoined tendon (rare)

Clavicle Fracture

- incidence: proximal (5%), middle (80%), or distal (15%) third of clavicle
- common in children (unites rapidly without complications)

Open Reduction and Internal Fixation vs. Nonsurgical Treatment in Displaced Midshaft Clavicle Fractures: A Meta-Analysis
J Orthop Trauma 2018;32(7):e276-e283
Purpose: Compare outcomes from ORIF and non-operative treatments in displaced mid-shaft clavicular fractures.
Methods: Meta-analysis with 9 RCTs reporting nonunion, functional outcomes, and subsequent surgeries in patients older than 16 yr.
Results: 9 randomized clinical trials with 1027 total patients were included. ORIF was associated with significantly lower nonunion rate of 1.7% compared to 14.5% for the non-operative treatment groups (RR 0.15, 95% CI, 0.08-0.31). Functional outcomes, rated by either DASH or Constant scores, were significantly better in ORIF up to 6 mo. When excluding elective plate removal, the rate of subsequent surgeries was significantly lower in the ORIF cohort (4.7% vs. 14%, RR 0.36, 95% CI 0.24-0.56).
Conclusions: ORIF is associated with significant reductions in nonunions and earlier functional outcomes in displaced midshaft clavicular fractures.

Mechanism
- fall on shoulder (87%), direct trauma to clavicle (7%), FOOSH (6%)

Clinical Features
- pain and tenting of skin
- arm is clasped to chest to splint shoulder and prevent movement

Investigations
- evaluate NVS of entire upper limb
- x-ray: AP, 45° cephalic tilt (superior/inferior displacement), 45° caudal tilt (AP displacement)
- CT: useful for medial physeal fractures and sternoclavicular injury

Treatment
- medial and middle-third clavicle fractures
  - for nondisplaced fractures, simple sling for 1-2 wk prn
  - early ROM and strengthening once pain subsides
  - if fracture is shortened >2 cm, consider ORIF
- distal-third clavicle fractures
  - undisplaced (with ligaments intact): sling for 1-2 wk
  - displaced (CC ligament injury): ORIF

Associated Injuries with Clavicle Fractures
- Up to 9% of clavicle fractures are associated with other fractures (most commonly rib fractures)
- Majority of brachial plexus injuries are associated with proximal third fractures

Specific Complications (see *General Fracture Complications*, OR7)
- cosmetic bump (most common complication)
- shoulder stiffness, weakness with repetitive activity
- pneumothorax, brachial plexus injuries, and subclavian vessel (all very rare)

Frozen Shoulder (Adhesive Capsulitis)

- disorder characterized by progressive pain and stiffness of the shoulder, usually resolving spontaneously within 18 mo

Stages of Adhesive Capsulitis
1. Freezing phase: gradual onset, diffuse pain (lasts 6-9 mo)
2. Frozen phase: decreased ROM impacts function (lasts 4-9 mo)
3. Thawing phase: gradual return of motion (lasts 5-26 mo)

Mechanism
- primary adhesive capsulitis
  - idiopathic, often associated with DM
  - usually resolves spontaneously in 9-18 mo
- secondary adhesive capsulitis
  - due to prolonged immobilization
  - shoulder-hand syndrome: CRPS/RSD characterized by arm and shoulder pain, decreased motion, and diffuse swelling
  - following MI, stroke, shoulder trauma
  - poorer outcomes

Clinical Features
- gradual onset (weeks to months) of diffuse shoulder pain with:
  - decreased active AND passive ROM
  - pain worse at night and often prevents sleeping on affected side
  - increased stiffness as pain subsides: continues for 6-12 mo after pain has disappeared

Conditions Associated with an Increased Incidence of Adhesive Capsulitis
- Prolonged immobilization (most significant)
- Female gender
- Age >49
- DM (5x)
- Cervical disc disease
- Hyperthyroidism
- Stroke
- MI
- Trauma and surgery
- Autoimmune disease

Investigations
- x-ray: AP (neutral, internal/external rotation), scapular Y, and axillary views of the shoulder
  - may be normal, or may show demineralization from disease

Treatment
- freezing phase
  - maintenance of active and passive ROM (physiotherapy)
  - NSAIDs and steroid injections if limited by pain
- thawing phase
  - aggressive physiotherapy, possible manipulation under anesthesia and early physiotherapy
  - arthroscopy for debridement/decompression

Humerus

Proximal Humeral Fracture

Mechanism
- young: high energy trauma (MVC)
- elderly: FOOSH from standing height in osteoporotic individuals

Neer Classification
Based on 4 parts of humerus
- Greater tuberosity
- Lesser tuberosity
- Humeral head
- Shaft

One-part fracture: any of the 4 parts with none displaced
Two-part fracture: any of the 4 parts with 1 displaced
Three-part fracture: displaced fracture of surgical neck + displaced greater tuberosity or lesser tuberosity
Four-part fracture: displaced fracture of surgical neck + both tuberosities

Clinical Features
- proximal humeral tenderness, deformity with severe fracture, swelling, painful ROM, bruising extends down arm and chest
- physical exam usually reveals diminished forward elevation, with or without disuse atrophy of deltoid and periscapular musculature

Investigations
- test axillary nerve function (deltoid contraction and skin over deltoid)
- x-rays: AP, trans-scapular, and axillary views of the shoulder are essential
- CT scan: to evaluate for tuberosity or articular involvement and fracture displacement, and if the diagnosis of non-union is unclear

Classification
- Neer classification is based on 4 fracture locations or 'parts'
- displaced: displacement >1 cm and/or angulation >45°
- the Neer system regards the number of displaced fractures, not the fracture line, in determining classification
- ± dislocated/subluxed: humeral head dislocated/subluxed from glenoid

Treatment
- assess for and treat osteoporosis if needed
- non-operative
  - nondisplaced and minimally displaced (85% of patients): broad arm sling immobilization, begin ROM within 14 d to prevent stiffness
  - most displaced fractures in low-demand elderly patients
- operative
  - ORIF (anatomic neck fractures, displaced, associated irreducible glenohumeral joint dislocation) or IM nail (surgical neck)
  - hemiarthroplasty or reverse TSA may be necessary, especially in elderly
  - minimally invasive percutaneous pinning and intramedullary nail fixation are indicated in rare instances

Specific Complications (see *General Fracture Complications*, OR7)
- AVN, nerve palsy (45%; typically axillary nerve), malunion, post-traumatic arthritis, persistent pain and weakness, frozen shoulder

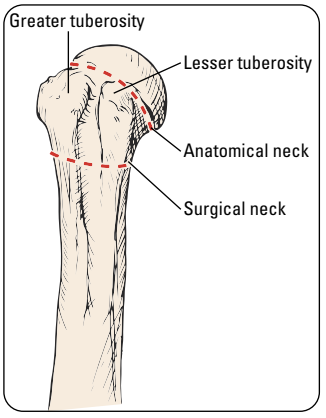

Figure 15. Fractures of the proximal humerus

Humeral Shaft Fracture

Mechanism
- high energy: direct blows/MVC (especially young)
- low energy: FOOSH, twisting injuries, metastases (in elderly)

Clinical Features
- pain, swelling, weakness ± shortening, motion/crepitus at fracture site
- must test radial nerve function before and after treatment: look for drop wrist, sensory impairment in dorsum of hand

Investigations
- x-ray: AP and lateral views of the humerus, including the shoulder and elbow joints

Treatment
- in general, humeral shaft fractures are treated non-operatively
- non-operative
  - ± reduction; can accept deformity due to compensatory ROM of shoulder
  - hanging cast (weight of arm in cast provides traction across fracture site) with collar and cuff sling immobilization until swelling subsides, then Sarmiento functional brace, followed by ROM
- operative
  - indications: see *NO CAST* sidebar, OR6, pathological fracture, "floating elbow" (simultaneous unstable humeral and forearm fractures)
  - ORIF: plating (most common), IM rod insertion, external fixation (rare)

Acceptable Humeral Shaft Deformities for Non-Operative Treatment
- <20° anterior angulation
- <30° varus angulation
- <3 cm of shortening

Risk of radial nerve and brachial artery injury

Specific Complications (see *General Fracture Complications*, OR7)
- failure of functional bracing (seen in up to 30% of patients)
- radial nerve palsy: expect spontaneous recovery in 3-4 mo, otherwise send for EMG
- non-union: most frequently seen in middle 1/3
- decreased ROM
- compartment syndrome

Distal Humeral Fracture

Mechanism
- young: high energy trauma (MVC)
- elderly: lower energy falls in patients with osteoporotic bone

Clinical Features
- elbow pain and swelling
- assess brachial artery

The anterior humeral line refers to an imaginary line drawn along the anterior surface of the humeral cortex that passes through the middle third of the capitellum when extended inferiorly. In subtle supracondylar fractures, the anterior humeral line is disrupted, typically passing through the anterior third of the capitellum

Investigations
- x-ray: AP and lateral views of the humerus and elbow
- CT scan: helpful when suspecting shear fracture of capitulum or trochlea, and for preoperative planning
- assess NVS: radial, ulnar, and median nerve

Classification
- supracondylar, distal single column, distal bicolumnar, and coronal shear fractures

Treatment
- goal is to restore a functional ROM of at least 30-130° flexion (unsatisfactory outcomes in 25%)
- non-operative (paediatric patients and elderly patients with medical comorbidities)
  - cast immobilization (in supination for lateral condyle fracture; pronation for medial condyle fractures): short immobilization and early range of motion
- operative
  - indications: displaced, supracondylar, bicolumnar
  - closed reduction and percutaneous pinning (children); ORIF; total elbow arthroplasty (complex bicolumnar in elderly)
  - adult fractures are almost always treated operatively due to risk of elbow stiffness with non-operative management

Elbow

Supracondylar Fracture

- subclass of distal humerus fracture: extra-articular, fracture proximal to capitulum and trochlea, usually transverse
- most common in paediatric population (peak age ~7 yr), rarely seen in adults
- AIN (median nerve) injury commonly associated with extension type

Mechanism
- >96% are extension injuries via FOOSH (e.g. fall off monkey bars); <4% are flexion injuries

Clinical Features
- pain, swelling, point tenderness
- neurovascular injury: median and radial nerves, radial artery

Investigations
- x-ray: AP and lateral views of the elbow
  - disruption of anterior humeral line suggests supracondylar fracture
  - fat pad sign: a sign of effusion and can be indicative of occult fracture
  - assess NVS: median and radial nerves, radial artery

Treatment
- non-operative
  - nondisplaced (paediatric): long arm plaster slab in 90° flexion x 3 wk
- operative
  - indications: displaced >50%, vascular injury, open fracture
  - requires percutaneous pinning followed by limb cast with elbow flexed <90°
  - in adults, ORIF is necessary

Specific Complications (see *General Fracture Complications*, OR7)
- stiffness is most common
- brachial artery injury (kinking can occur if displaced fracture), median or ulnar nerve injury, compartment syndrome (leads to Volkmann's ischemic contracture), malalignment cubitus varus (distal fragment tilted into varus)

Three Joints at the Elbow
Humeroradial joint
Humeroulnar joint
Radioulnar joint

Normal carrying angle of elbow is ~10° of valgus

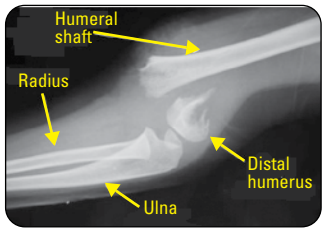

Figure 16. X-ray of transverse displaced supracondylar fracture of humerus with elbow dislocation

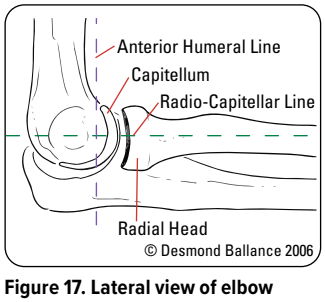

Figure 17. Lateral view of elbow

Radial Head Fracture

- a common fracture of the upper limb in young adults

Mechanism
- FOOSH with elbow extended and forearm pronated

Clinical Features
- marked local tenderness on palpation over radial head (lateral elbow)
- decreased ROM at elbow, ± mechanical block to forearm pronation and supination
- pain on pronation/supination

Investigations
- x-ray: AP and lateral views of the elbow
  - enlarged anterior fat pad ("sail sign") or the presence of a posterior fat pad on lateral view indicates effusion, which could occur with occult radial head fractures

Table 12. Classification and Treatment of Radial Head Fractures

Mason Class	Radiographic Description	Treatment
1	Nondisplaced fracture	Elbow slab or sling x 3-5 d with early ROM
2	Displaced fracture	ORIF if: angulation >30°, involves ≥1/3 of the radial head, or if ≥3 mm of joint incongruity exists, block to forearm rotation
3	Comminuted fracture	Radial head excision ± prosthesis (if ORIF not feasible)
4	Comminuted fracture with posterior elbow dislocation	Radial head excision ± prosthesis

Treatment
- ORIF remains the gold standard in management
- arthroscopic repair can be considered: offers improved visualization and enhances soft tissue preservation of the joint

Specific Complications (see *General Fracture Complications*, OR7)
- myositis ossificans – calcification of muscle
- recurrent instability (if MCL injured and radial head excised)

Terrible Triad
Radial head fracture
Coronoid fracture
Elbow dislocation

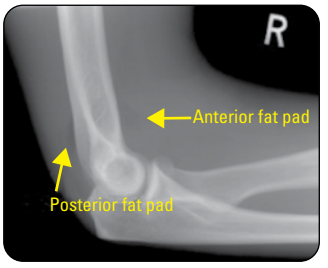

Figure 18. Lateral x-ray of elbow with effusion ("sail sign")

To avoid stiffness, do not immobilize elbow joint >2-3 wk

Olecranon Fracture

Mechanism
- direct trauma to posterior aspect of elbow (fall onto the point of the elbow) or FOOSH

Clinical Features
- localized pain, palpable defect
- ± loss of active extension due to avulsion of triceps tendon

Investigations
- x-ray: AP and lateral (require true lateral to determine fracture pattern)

Treatment
- non-operative
  - non-displaced (<2 mm, stable): cast x 2-3 wk (elbow in 90° flexion, often in full elbow extension), then gentle ROM
- operative
  - displaced: ORIF (plate and screws or tension-band wiring) and early ROM if stable

Elbow Dislocation

- third most common joint dislocation after shoulder and patella
- anterior capsule and collateral ligaments disrupted

Elbow Dislocation
The radio-capitellar line refers to an imaginary line along the longitudinal axis of the radial neck that passes through the centre of the capitellum, regardless of the degree of elbow flexion. If the radio-capitellar line does not pass through the centre of the capitellum a dislocation should be suspected

Mechanism
- elbow hyperextension via FOOSH or valgus/supination stress during elbow flexion
- usually the radius and ulna are dislocated together, alternatively the radial head dislocates in isolation and the ulna is fractured ("Monteggia Fracture")
- 80% are posterior/posterolateral, anterior are rare and usually devastating

Clinical Features
- elbow pain, swelling, deformity
- flexion contracture
- ± absent radial or ulnar pulses

Investigations
- x-ray: AP and lateral views of the elbow
- assess NVS: brachial artery, median and ulnar nerves

Treatment
- non-operative
  - closed reduction under conscious sedation (post-reduction x-rays required)
  - Parvin's method: patient lies prone with arm hanging down; apply gentle traction downwards on wrist; as olecranon slips distally, gently lift up the arm at elbow to reduce joint
  - long-arm splint with forearm in neutral rotation and elbow in 90° flexion
  - early ROM (<2 wk)
- operative
  - indications: complex dislocation or persistent instability after closed reduction
  - ORIF

Specific Complications (see *General Fracture Complications*, OR7)
- stiffness (loss of extension), intra-articular loose body, neurovascular injury (ulnar nerve, median nerve, brachial artery), radial head fracture
- recurrent instability uncommon

Epicondylitis

- lateral epicondylitis = "tennis elbow," inflammation of the common extensor tendon as it inserts into the lateral epicondyle
- medial epicondylitis = "golfer's elbow," inflammation of the common flexor tendon as it inserts into the medial epicondyle

Tennis Elbow = la**T**eral epicondylitis; pain associated with ex**T**ension of wrist

Mechanism
- repeated or sustained contraction of the forearm muscles/chronic overuse

Clinical Features
- point tenderness over humeral epicondyle and/or distal to it over forearm musculature
- pain upon resisted wrist extension (lateral epicondylitis) or wrist flexion (medial epicondylitis)
- generally a self-limited condition, but may take 6-18 mo to resolve

Treatment
- non-operative (very good outcomes)
  - rest, ice, NSAIDs
  - use brace/strap
  - physiotherapy, stretching, and strengthening
  - activity modification/ergonomics
  - corticosteroid injection
- operative
  - indication: failed 6-12 mo conservative therapy
  - percutaneous or open release of common tendon from epicondyle

Elbow Joint Injection
Inject at the centre of the triangle formed by the lateral epicondyle, radial head, and olecranon

Forearm

Radius and Ulna Shaft Fractures

Mechanism
- high-energy direct or indirect (MVA, fall from height, sports) trauma
- fractures usually accompanied by displacement due to high force

Clinical Features
- deformity, pain, swelling
- loss of function in hand and forearm

Investigations
- x-ray: AP and lateral of forearm ± oblique of elbow and wrist
- CT if fracture is close to joint

Treatment
- goal is anatomic reduction since imperfect alignment significantly limits forearm pronation and supination
- ORIF with plates and screws; closed reduction with immobilization usually yields poor results for displaced forearm fractures (except in children)

Specific Complications (see *General Fracture Complications*, OR7)
- compartment syndrome
- soft tissue contracture resulting in limited forearm rotation – surgical release of tissue may be warranted

Monteggia Fracture

- fracture of the proximal ulna with radial head dislocation and proximal radioulnar joint injury
- more common and better prognosis in the paediatric age group when compared to adults

Mechanism
- direct blow to the posterior aspect of the forearm
- hyperpronation
- fall on the hyperextended elbow

Clinical Features
- pain, swelling, decreased rotation of forearm ± palpable lump at the radial head
- ulna angled apex anterior and radial head dislocated anteriorly (rarely the reverse deformity occurs)

Investigations
- x-ray: AP and lateral views of the elbow, wrist, and forearm

Treatment
- adults: ORIF of ulna with indirect reduction of radiocapitellar joint in 90% of patients (open reduction of radiocapitellar joint if unsuccessful)
- splint and early postoperative ROM if elbow completely stable, otherwise immobilization in plaster with elbow flexed for 2-3 wk
- paediatrics: attempt closed reduction and immobilization in plaster with elbow flexed for Bado Type I-III, surgery for Type IV

Specific Complications (see *General Fracture Complications*, OR7)
- PIN injury: most common nerve injury; observe for 3 mo as most resolve spontaneously
- radial head instability/redislocation
- radioulnar synostosis

Nightstick Fracture

- isolated fracture of ulna without dislocation of radial head

Mechanism
- direct downward blow to upward block forearm (e.g. holding arm up to protect face)

Treatment
- non-operative
  - indication: non-displaced
  - below elbow cast (x 10 d), followed by forearm brace (~8 wk)
- operative
  - indication: significantly displaced
  - ORIF if >50% shaft displacement or >10° angulation

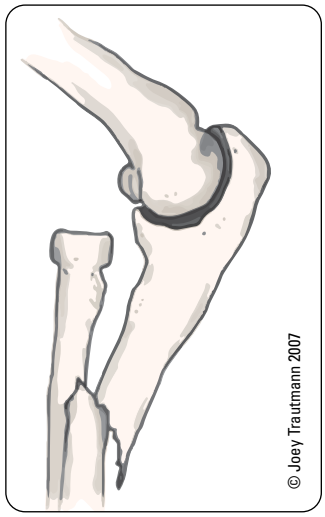

Figure 19. Monteggia fracture

In all isolated ulna fractures, assess proximal radius to rule out a Monteggia fracture

Bado Type Classification of Monteggia Fractures
Based on the direction of displacement of the dislocated radial head, generally the same direction as the apex of the ulnar fracture
Type I: anterior dislocation of radial head and proximal/middle third ulnar fracture (60%)
Type II: posterior dislocation of radial head and proximal/middle third ulnar fracture (15%)
Type III: lateral dislocation of radial head and metaphyseal ulnar fracture (20%)
Type IV – combined: proximal fracture of the ulna and radius, dislocation of the radial head in any direction (<5%)

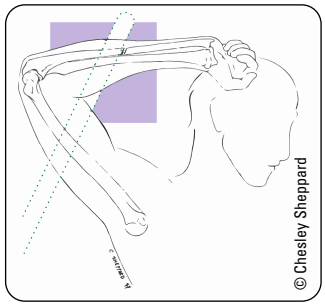

Figure 20. Nightstick fracture

Galeazzi Fracture

- fracture of the distal radial shaft with disruption of the DRUJ
- most commonly in the distal 1/3 of radius near junction of metaphysis/diaphysis

Mechanism
- FOOSH with axial loading of pronated forearm or direct wrist trauma
- forceful axial loading of radial shaft (e.g. direct trauma to distal 1/3 of radius)

Clinical Features
- pain, swelling, deformity, and point tenderness at fracture site

Investigations
- x-ray: AP, and lateral views of the elbow, wrist, and forearm
  - shortening of distal radius >5 mm relative to the distal ulna
  - widening of the DRUJ space on AP
  - dislocation of radius with respect to ulna on true lateral

Treatment
- all cases are operative ("fracture of necessity")
  - ORIF of radius; afterwards, assess DRUJ stability by balloting distal ulna relative to distal radius
  - if DRUJ is stable and reduced, splint for 10-14 d with early ROM encouraged
  - if DRUJ is unstable, ORIF or percutaneous pinning with long arm cast in supination x 2-3 wk

For all isolated radius fractures assess DRUJ to rule out a Galeazzi fracture

Monteggia vs. Galeazzi Fractures
Remember the mnemonic "**MUGGER**":
Monteggia
Ulnar fracture
Galeazz
Radial fracture

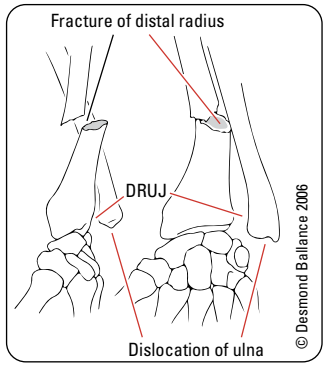

Figure 21. Galeazzi fracture

Wrist

Colles' Fracture

- extra-articular transverse distal radius fracture (~2 cm proximal to the radiocarpal joint) with dorsal displacement ± ulnar styloid fracture
- most common fracture in those >40 yr, especially in women and those with osteoporotic bone

Mechanism
- FOOSH

Clinical Features
- "dinner fork" deformity
- swelling, ecchymosis, tenderness

Investigations
- x-ray: AP and lateral ± oblique views of wrist

Treatment
- goal is to restore radial height (13 mm), radial inclination (22°), volar tilt (11°), as well as DRUJ stability and useful forearm rotation
- non-operative
  - closed reduction (think opposite of the deformity)
  - hematoma block (sterile prep and drape, local anesthetic injection directly into fracture site) or conscious sedation
  - closed reduction: traction with extension (exaggerate injury); traction with ulnar deviation, pronation, flexion (of distal fragment – not at wrist)
  - dorsal slab/below elbow cast for 5-6 wk
  - obtain post-reduction films immediately; repeat reduction if necessary
  - x-ray at 1 wk, 3 wk, and at cessation of immobilization to ensure reduction is maintained
- operative
  - indication: failed closed reduction, or loss of reduction
  - percutaneous pinning, external fixation, or ORIF

Indications for Direct Surgical Management of Colles' Fracture
- Displaced intra-articular fracture
- Comminuted
- Severe osteoporosis
- Dorsal angulation >5° or volar tilt >20°
- >5 mm radial shortening

Features of Inadequate Closed Reduction that Require ORIF
- Radial shortening >3 mm or
- Dorsal tilt >10° or
- Intra-articular displacement/step-off >2 mm

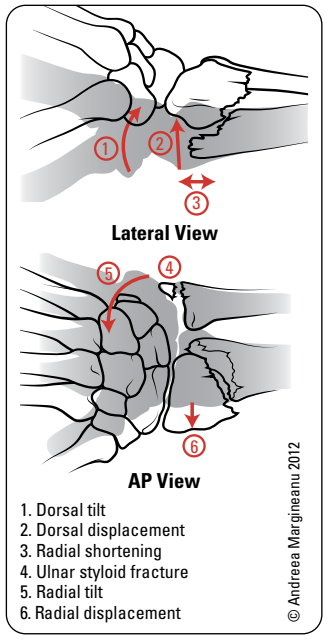

Figure 22. Colles' fracture and associated bony deformity

Smith's Fracture

- volar displacement of the distal radius (i.e. reverse Colles' fracture)

Mechanism
- fall onto the back of the flexed hand

Investigations
- x-ray: AP and lateral ± oblique views of wrist

Treatment
- usually unstable and needs ORIF
- if patient is poor operative candidate, may attempt non-operative treatment
  - closed reduction with hematoma block (reduction opposite of Colles')
  - long-arm cast in supination x 6 wk

Complications of Wrist Fractures

- most common complications are poor grip strength, stiffness, and radial shortening
- distal radius fractures in individuals <40 yr of age are frequently high energy/comminuted and are more likely to require ORIF
- 80% have normal function in 6-12 mo

Table 13. Early and Late Complications of Wrist Fractures

Early	Late
Difficult reduction ± loss of reduction	Malunion, radial shortening
Compartment syndrome	Painful wrist secondary to ulnar prominence
Extensor pollicis longus tendon rupture	Frozen shoulder ("shoulder-hand syndrome")
Acute carpal tunnel syndrome	Post-traumatic arthritis
Finger swelling with venous block	Carpal tunnel syndrome
Complications of a tight cast/splint	CRPS/RSD

Scaphoid Fracture

Epidemiology
- most common carpal bone injured
- common in young men; not common in children or in patients beyond middle age
- may be associated with other carpal or wrist injuries (e.g. Colles' fracture)

Mechanism
- FOOSH: impaction of scaphoid on distal radius, most commonly resulting in a transverse fracture through the waist (65%), distal (10%), or proximal (25%) scaphoid

Clinical Features
- pain with resisted pronation
- tenderness in the anatomical "snuff box", over scaphoid tubercle, and pain with long axis compression into scaphoid
- usually nondisplaced

Investigations
- x-ray: AP, lateral, and scaphoid views with wrist extension and ulnar deviation
- ± CT or MRI: detect occult fracture and prevent AVN
- bone scan rarely used
  - note: a fracture may not be radiologically evident up to 2 wk after acute injury, so if a patient complains of wrist pain and has anatomical snuff box tenderness but a negative x-ray, treat as if positive for a scaphoid fracture and repeat x-ray 2 wk later to rule out a fracture; if x-ray still negative, order CT or MRI

Treatment
- early treatment critical for improving outcomes
- non-operative
  - non-displaced (<1 mm displacement/<15° angulation): long-arm thumb spica cast x 4 wk, then short arm cast until radiographic evidence of healing is seen (2-3 mo)
- operative
  - displaced: ORIF with headless/countersink compression screw is the mainstay treatment

Specific Complications (see *General Fracture Complications*, OR7)
- most common: nonunion/malunion (use bone graft from iliac crest or distal radius with fixation to heal)
- AVN of the proximal fragment
- delayed union (recommend surgical fixation)
- scaphoid nonunion advanced collapse (SNAC) – chronic nonunion leading to advanced collapse and arthritis of wrist

Prognosis
- proximal pole: proximal fifth fracture, AVN rate 100%; proximal third fracture: AVN rate 33%
- waist: middle of the scaphoid fractures have healing rates of 80-90%
- distal pole: distal third fractures have healing rates close to 100%

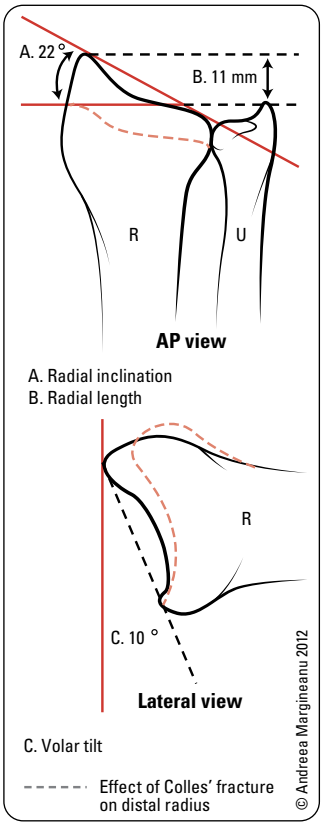

Figure 23. Normal wrist angles+ wrist angles in Colles' fracture
Note the relative shortening of the radius relative to the ulna on AP view in Colles' fracture

Scaphoid Fracture Special Tests
Tender snuff box: 100% sensitivity, but 29% specific, as it is also positive with many other injuries of radial aspect of wrist with FOOSH

The proximal pole of the scaphoid receives as much as 100% of its arterial blood supply from the radial artery that enters at the distal pole. A fracture through the proximal third disrupts this blood supply and results in a high incidence of AVN/nonunion

Figure 24. ORIF left scaphoid

Spine

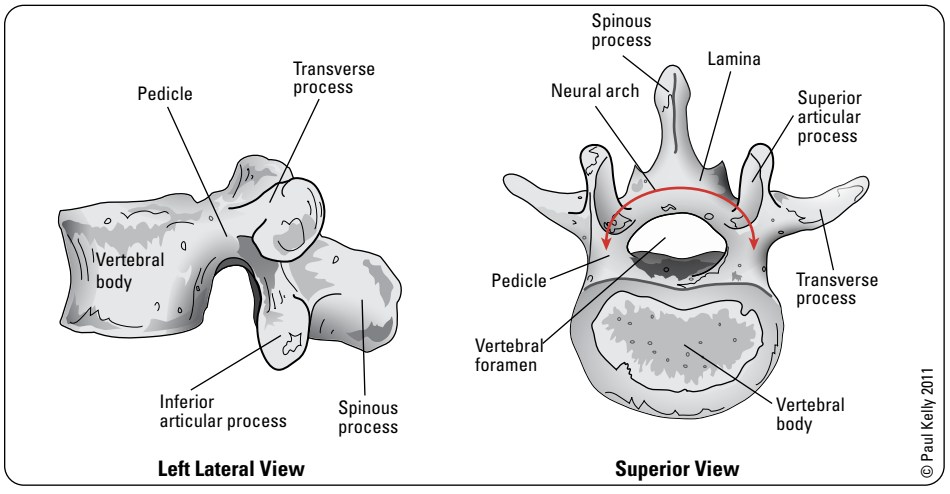

Figure 27. Schematic diagram of vertebral anatomy
Adapted from: Moore KL, Agur AMR. Essential Clinical Anatomy, 3rd ed. Philadephia: Lippincott Williams and Wilkins, 2007. p274

Fractures of the Spine

- see Neurosurgery, NS39

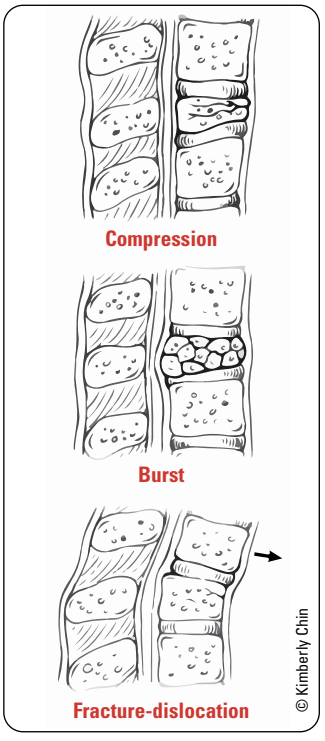

Figure 26. Compression, burst, and dislocation fractures of the spine

Cervical Spine

General Principles

- C1 (atlas): no vertebral body, no spinous process
- C2 (axis): odontoid = dens
- 7 cervical vertebrae; 8 cervical nerve roots
- nerve root exits above vertebra (i.e. C4 nerve root exits above C4 vertebra), C8 nerve root exits below C7 vertebra
- radiculopathy = impingement of nerve root
- myelopathy = impingement of spinal cord

Special Testing

- compression test: pressure on head worsens radicular pain
- distraction test: traction on head relieves radicular symptoms
- Valsalva test: Valsalva maneuver increases intrathecal pressure and causes radicular pain
- Lhermitte Sign: electric shock sensation radiating to back upon forward flexion of the neck, some etiologies include multiple sclerosis, cervical myelopathy, and B_{12} deficiency
- occiput-wall distance (OWD): patient stands against a wall with erect posture and distance between the occiput and the wall is measured, value greater than 2 cm is abnormal, indicative of thoracic hyper-kyphosis

Table 14. Cervical Radiculopathy/Neuropathy

Root	C5	C6	C7	C8
Motor	Deltoid Biceps Wrist extension	Biceps Brachioradialis	Triceps Wrist flexion Finger extension	Interossei Digital flexors
Sensory	Axillary nerve (patch over lateral deltoid)	Thumb	Index and middle finger	Ring and little finger
Reflex	Biceps	Biceps Brachioradialis	Triceps	Finger jerk

X-Rays for C-Spine
- AP spine: alignment
- AP odontoid: atlantoaxial articulation
- lateral
  - vertebral alignment: posterior vertebral bodies should be aligned (translation >3.5 mm is abnormal)
  - angulation: between adjacent vertebral bodies (>11° is abnormal)
  - disc or facet joint widening
  - anterior soft tissue space (at C3 should be ≤3 mm; at C4 should be ≤8-10 mm)
- oblique: evaluate pedicles and intervertebral foramen
- ± swimmer's view: lateral view with arm abducted 180° to evaluate C7-T1 junction if lateral view is inadequate
- ± lateral flexion/extension view: evaluate subluxation of cervical vertebrae

Differential Diagnosis of C-Spine Pain
- neck muscle strain, cervical spondylosis, cervical stenosis, RA (spondylitis), traumatic injury, whiplash, myofascial pain syndrome, acute discogenic nerve root entrapment, infection, fracture, neoplasm, pain from soft tissue structure

C-SPINE INJURY
- see Neurosurgery, NS38

Thoracolumbar Spine

General Principles
- spinal cord terminates at conus medullaris (L1/2)
- individual nerve roots exit below pedicle of vertebra (i.e. L4 nerve root exits below L4 pedicle)

Special Tests
- **straight leg raise**: passive lifting of leg (30-70°) reproduces radicular symptoms of pain radiating down posterior/lateral leg to knee ± into foot
- **Lasegue maneuver**: dorsiflexion of foot during straight leg raise makes symptoms worse, or if leg is less elevated, dorsiflexion will bring on symptoms
- **femoral stretch test**: with patient prone, flexing the knee of the affected side and passively extending the hip results in radicular symptoms of unilateral pain in anterior thigh

Table 15. Lumbar Radiculopathy/Neuropathy

Root	L4	L5	S1
Motor	Quadriceps (knee extension + hip adduction) Tibialis anterior (ankle inversion + dorsiflexion)	Extensor hallucis longus Gluteus medius (hip abduction)	Peroneus longus + brevis (ankle eversion) Gastrocnemius + soleus (plantar flexion)
Sensory	Medial malleolus	1st dorsal webspace and lateral leg	Lateral foot
Screening Test	Squat and rise	Heel walking	Walking on toes
Reflex	Knee (patellar)	Medial hamstring*	Ankle (Achilles)
Test	Femoral stretch	Straight leg raise	Straight leg raise

Differential Diagnosis of Back Pain
1. mechanical or nerve compression (>90%)
   - degenerative (disc, facet, ligament)
   - nerve root compression (e.g. disc herniation)
   - spinal stenosis (congenital, osteophyte, central disc)
2. others (<10%)
   - neoplastic (primary, metastatic, multiple myeloma)
   - infectious (osteomyelitis, TB)
   - metabolic (osteoporosis)
   - traumatic fracture (compression, distraction, translation, rotation)
   - spondyloarthropathies (ankylosing spondylitis)
   - referred (aorta, renal, ureter, pancreas)

DEGENERATIVE DISC DISEASE
- loss of vertebral disc height with age resulting in:
  - bulging and tears of annulus fibrosus
  - change in alignment of facet joints
  - osteophyte formation

Mechanism
- compression and dehydration of disc material over time with age

Clinical Features
- axial back pain
- pain worse with axial loading and flexion
- negative straight leg raise

Investigations
- x-ray, MRI, provocative discography
- imaging only indicated if symptoms persist greater than 6 wk or if red flag symptoms are present

Treatment
- non-operative
  - staying active with modified activity
  - back strengthening
  - NSAIDs
  - do NOT treat with opioids; no proven efficacy of spinal traction or manipulation
- operative – rarely indicated
  - decompression ± fusion (in cases of severe or progressive neurological deficit; refractory cases with impaired quality of life)

SPINAL STENOSIS
- narrowing of spinal canal
- congenital (idiopathic, osteopetrosis, achondroplasia) or acquired (degenerative, iatrogenic – post spinal surgery, ankylosing spondylosis, Paget's disease, trauma)

Clinical Features
- ± bilateral back and leg pain
- neurogenic claudication
- ± motor weakness

Investigations
- CT/MRI reveals narrowing of spinal canal

Treatment
- non-operative
  - physiotherapy (flexion exercises, stretch/strength exercises), NSAIDs, lumbar epidural steroids
- operative
  - indication: non-operative failure >6 mo
  - decompressive surgery

Table 16. Differentiating Claudication

	Neurogenic	Vascular
Aggravation	With standing/walking Walking distance variable	Walking/exercise (reproducible)
Alleviation	Change in position (usually flexion, sitting, lying down)	Stop walking/exercise
Time	Relief in ~10 min	Relief in ~2 min

MECHANICAL BACK PAIN
- back dominant pain that does not involve nerve impingement

Clinical Features
- dull backache aggravated by activity and prolonged standing (or sitting, depending on cause and pathology)
- morning stiffness (e.g. if facet OA)
- no neurological signs

Treatment
- symptomatic (analgesics, physiotherapy, weight loss, and exercise program)
- prognosis: symptoms may resolve in 4-6 wk, others become chronic

LUMBAR DISC HERNIATION
- tear in annulus fibrosus allows protrusion of nucleus pulposus, causing either a central, posterolateral, or lateral disc herniation, most commonly at L5-S1 > L4-5 > L3-4
- M:F=3:1
- only 5% become symptomatic
- usually a history of flexion-type injury

Clinical Features
- back dominant pain (central herniation) or leg dominant pain (lateral herniation)
- tenderness between spinous processes at affected level
- muscle spasm ± loss of normal lumbar lordosis

Cauda equina syndrome and ruptured aortic aneurysms are causes of low back pain that are considered surgical emergencies

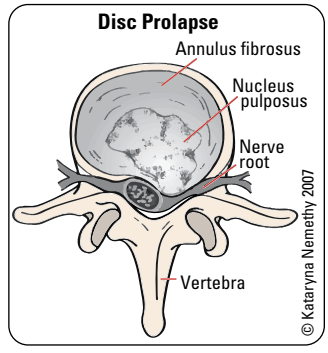

Figure 28. Disc herniation causing nerve root compression

- neurological disturbance is segmental and varies with level of central herniation
  - motor weakness (L4, L5, S1)
  - diminished reflexes (L4, S1)
  - diminished sensation (L4, L5, S1)
- positive straight leg raise
- positive contralateral SLR
- positive Lasegue and Bowstring sign
- cauda equina syndrome (present in 1-10%): surgical emergency

Neurogenic claudication is position dependent; vascular claudication is exercise dependent

Investigations
- x-ray, MRI, consider a post-void residual volume to check for urinary retention; post-void >100 mL should heighten suspicion for cauda equina syndrome

MRI abnormalities (e.g. spinal stenosis, disc herniation) are quite common in both asymptomatic and symptomatic individuals and are not necessarily an indication for intervention without clinical correlation

Treatment
- non-operative
  - symptomatic
    - extension protocol physiotherapy program
    - NSAIDs
- operative
  - indication: progressive neurological deficit, failure of symptoms to resolve within 3 mo, or cauda equina syndrome due to central disc herniation
  - surgical discectomy
- prognosis
  - 90% of patients improve in 3 mo with non-operative treatment

Red Flags for

BACK PAIN
Bowel or bladder dysfunction
Anesthesia (saddle)
Constitutional symptoms/malignancy
Khronic disease
Paresthesias
Age >50 yr
IV drug use
Neuromotor deficits

Sciatica
- Most common symptom of radiculopathy (L4-S3)
- Leg dominant, constant, burning pain
- Pain radiates down leg ± foot
- Most common cause = disc herniation

Table 17. Types of Low Back Pain

	Mechanical Back Pain		Direct Nerve Root Compression	
	Disc Origin	**Facet Origin**	**Spinal Stenosis**	**Root Compression**
Pain Dominance	Back	Back	Leg	Leg
Aggravation	Flexion	Extension, standing, walking	Exercise, extension, walking, standing	Flexion
Onset	Gradual	More sudden	Congenital or acquired	Acute leg ± back pain
Duration	Long (weeks, months)	Shorter (days, weeks)	Acute or chronic history (weeks to months)	Constant and severe pain, lasting weeks)
Treatment	Relief of strain, physiotherapy and exercise, weightloss, NSAIDs, acetaminophen	Relief of strain, physiotherapy and exercise, weightloss, NSAIDs, acetaminophen	Relief of strain, physiotherapy (flexion back program), surgical decompression if progressive or severe deficit, NSAIDs, acetaminophen	Relief of strain, physiotherapy (extension back program for disc herniation), surgical decompression if progressive or severe deficit, NSAIDs, acetaminophen

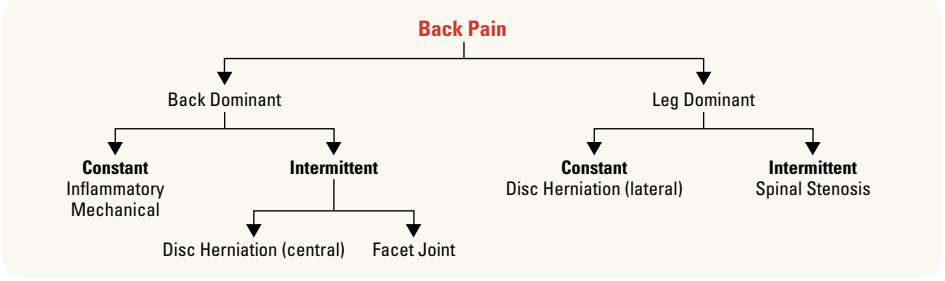

Figure 29. Approach to back pain

SPONDYLOLYSIS

Definition
- defect in the pars interarticularis with no movement of the vertebral bodies

Mechanism
- trauma: gymnasts, weightlifters, backpackers, loggers, labourers

Clinical Features
- activity-related back pain, pain with unilateral extension (Michelis' test)

Investigations
- oblique x-ray: "collar" break in the "Scottie dog's" neck
- bone scan
- CT scan

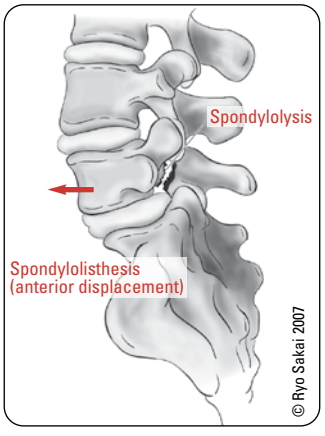

Figure 30. Spondylolysis, Spondylolisthesis

Treatment
- non-operative
  - activity restriction, brace, stretching exercise

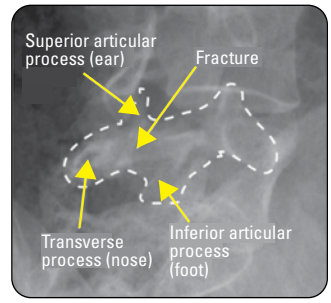

Figure 31. "Scottie dog" fracture

ADULT ISTHMIC SPONDYLOLISTHESIS

Definition
- defect in pars interarticularis causing a forward translation or slippage of one vertebra on another, usually at L5-S1, less commonly at L4-5

Mechanism
- degenerative (adults), traumatic, pathological, teratogenic

Clinical Features
- lower back pain radiating to buttocks relieved with sitting
- neurogenic claudication
- L5 radiculopathy
- Meyerding Classification (percentage of slip)

Investigations
- x-ray (AP, lateral, oblique flexion-extension views), MRI

Treatment
- non-operative
  - activity restriction, bracing, NSAIDs
- operative

Table 18. Classification and Treatment of Spondylolisthesis

Class	Percentage of Slip	Treatment
1	0-25%	Symptomatic operative fusion only for intractable pain
2	25-50	Same as above
3	50-75	Decompression for spondylolisthesis and spinal fusion
4	75-100	Same as above
5	>100	Same as above

Specific Complications
- may present as cauda equina syndrome due to roots being stretched over the edge of L5 or sacrum

Pelvis

Pelvic Fracture

Mechanism
- young: high energy trauma, either direct or by force transmitted longitudinally through the femur
- elderly: fall from standing height, low energy trauma
- lateral compression, vertical shear, or anteroposterior compression fractures

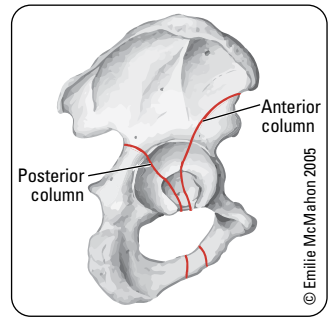

Figure 32. Pelvic columns

Clinical Features
- pain, inability to bear weight
- local swelling, tenderness
- abnormal lower extremity positioning: external rotation of one or both extremities, limb-length discrepancy
- pelvic instability

Investigations
- x-ray: AP pelvis, inlet and outlet views, Judet views (visualizes obturator and iliac oblique when acetabular fracture suspected)
  - 6 cardinal radiographic landmarks of the acetabulum: ilioischial line, iliopectineal line, teardrop, weight bearing roof, posterior rim, anterior rim
- CT scan useful for evaluating posterior pelvic injury and acetabular fracture (if stable)
  - may see contrast blush
- assess genitourinary injury (rectal exam, vaginal exam, hematuria, blood at urethral meatus)
  - if involved, the fracture is considered an open fracture

Classification

Table 19. Tile Classification of Pelvic Fractures

Type	Stability	Description
A	Rotationally stable Vertically stable	A1: fracture not involving pelvic ring (i.e. avulsion or iliac wing fracture) A2: minimally displaced fracture of pelvic ring (e.g. ramus fracture) A3: transverse sacral or coccygeal fracture
B	Rotationally unstable Vertically stable	B1: open book (external rotation) B2: lateral compression – ipsilateral B2-1: with anterior ring rotation/displacement through ipsilateral rami B2-2: with anterior ring rotation/displacement through non-ipsilateral rami (bucket-handle) B3: bilateral
C	Rotationally unstable Vertically unstable	C1: unilateral C1-1: iliac fracture, C1-2: sacroiliac fracture-dislocation C1-3: sacral fracture C2: bilateral with 1 side type B and 1 side type C C3: bilateral both sides type C

Possible Radiological Findings
- Pubic rami fractures: superior/inferior
- Pubic symphysis diastasis: common in AP compression (N=5 mm)
- Sacral fractures: common in lateral compression
- SI joint diastasis: common in AP compression (N=1-4 mm)
- Disrupted anterior column (iliopectineal line) or posterior column (ilioischial line)
- "Teardrop" displacement: acetabular fracture
- Iliac, ischial avulsion fractures
- Displacement of the major fragment: superior (VS), open book (APC), bucket handle (LC)

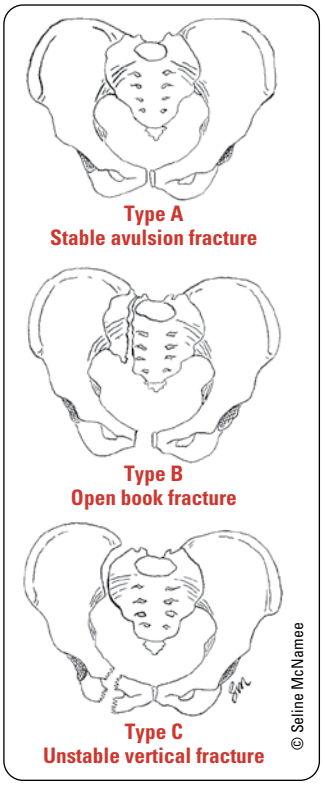

Figure 33. Tile classification of pelvic fractures

Treatment
- ABCDEs
- emergency management
  - IV fluids/blood
  - pelvic binder/sheet
  - ± pre-peritoneal packing
  - external fixation vs. emergent angiography/embolization
  - ± laparotomy (if FAST/DPL positive)
- non-operative treatment: protected weight bearing
  - indication: stable fracture (e.g. elderly patient with fracture sustained in fall from standing)
- operative treatment: ORIF
- indications
  - unstable pelvic ring injury
  - symphysis diastasis >2.5 cm
  - open fracture

Specific Complications (see *General Fracture Complications*, OR7)
- hemorrhage (life-threatening)
- injury to rectum or urogenital structures
- obstetrical difficulties, sexual and voiding dysfunctions
- persistent SI joint pain
- post-traumatic arthritis of the hip with acetabular fractures
- high-risk of DVT/PE

Hip

Hip Dislocation

- full trauma survey (see Emergency Medicine, *Patient Assessment/Management*, ER2)
- examine for neurovascular injury prior to open or closed reduction
- high index of suspicion for associated injuries
- reduce hip dislocations within 6 h to decrease risk of AVN of the femoral head
- hip precautions (no extreme hip flexion, adduction, internal or external rotation) for 6 wk post-reduction
- see *Hip Dislocation Post-Total Hip Arthroplasty*, OR32

ANTERIOR HIP DISLOCATION
- mechanism: posteriorly directed axial loading of the femur with hip widely abducted and externally rotated
- classified into inferior (flexion, abduction, external rotation) and superior (extension and external rotation)
- clinical features: shortened, abducted, externally rotated limb
- treatment
  - closed reduction under conscious sedation/GA
  - post-reduction CT to assess joint congruity

Up to 50% of patients with hip dislocations suffer fractures elsewhere at the time of injury

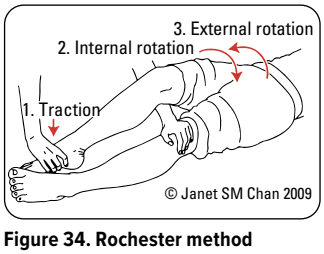

Figure 34. Rochester method

POSTERIOR HIP DISLOCATION

- most frequent type of hip dislocation (90%)
- mechanism: severe axial load to knee with hip flexed and adducted
  - e.g. knee into dashboard in MVC
- clinical features: shortened, adducted, internally rotated limb
- x-ray: affected femoral head will appear smaller than unaffected femoral head
- Thompson and Epstein classification – posterior dislocation:
  - I – with no or minor posterior acetabular wall fracture
  - II – with large posterior acetabular wall fracture
  - III – with comminuted acetabular fracture
  - IV – with acetabular floor fracture
  - V – with fracture of femoral head
- treatment
  - closed reduction under conscious sedation/GA only if no associated femoral neck fracture or ipsilateral displacement
  - ORIF if unstable, intra-articular fragments, or significant displacement
  - post-reduction CT to assess joint congruity and fractures

COMPLICATIONS FOR ALL HIP DISLOCATIONS

- post-traumatic OA
- AVN of femoral head
- associated fractures (e.g. femoral head, neck, or shaft)
- sciatic nerve palsy in 25% (10% permanent)
- HO
- thromboembolism – DVT/PE

Hip Fracture

General Features

- acute onset of hip pain after a fall
- unable to weight-bear
- shortened and externally-rotated leg
- painful ROM

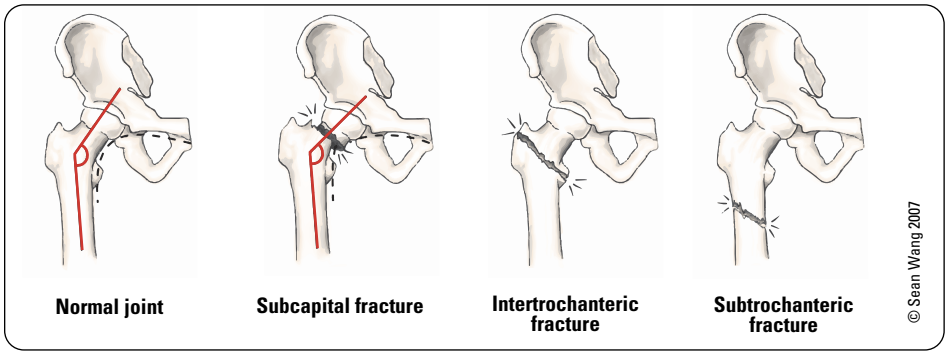

Figure 35. Subcapital, intertrochanteric, and subtrochanteric hip fractures

Table 20. Overview of Hip Fractures

Fracture Type	Definition	Mechanism	Investigations	Treatment	Complications
Femoral Neck (Subcapital)	Intracapsular	Young: MVC, fall from height Elderly: fall from standing, rotational force	X-Ray: AP hip, AP pelvis, cross table lateral hip	See Table 21, OR32	DVT, non-union, AVN, dislocation
Intertrochanteric Stable: intact posteromedial cortex Unstable: non-intact posteromedial cortex	Extracapsular fracture between the greater and lesser trochanters and transitional bone between the neck and shaft	Same as femoral neck fracture Direct or indirect force transmitted to the intertrochanteric area	X-Ray: AP hip, AP pelvis, cross table lateral hip	Closed reduction under fluoroscopy then dynamic hip screw or IM nail	DVT, varus displacement of proximal fragment, malrotation, non-union, failure of fixation device
Subtrochanteric	Fracture begins at or below the lesser trochanter and involves the proximal femoral shaft	Young: high energy trauma Elderly: osteopenic bone + fall, pathological fracture	X-Ray: AP pelvis, AP/lateral hip and femur	Closed/open reduction under fluoroscopy, then IM nail	Malalignment, non-union, wound infection

X-Ray Features of Subcapital Hip Fractures

- Disruption of Shenton's line (a radiographic line drawn along the upper margin of the obturator foramen, extending along the inferomedial side of the femoral neck)
- Altered neck-shaft angle (normal is 120-130°)

DVT Prophylaxis in Hip Fractures

LMWH (i.e. enoxaparin 40 mg SC BID), fondaparinux, low dose heparin on admission, do not give <12 h before surgery

AVN of Femoral Head

- Distal to proximal blood supply along femoral neck to head (medial and lateral femoral circumflex arteries)
- Susceptible to AVN if blood supply disrupted
- Etiology: femoral neck fracture, chronic systemic steroid use, SCFE, Legg-Calvé-Perthes, SLE, RA

Comparative Effectiveness of Pain Management Interventions for Hip Fracture: A Systematic Review

Ann Intern Med 2011;155(4):234-245

Study: Randomized controlled trials (RCTs); nonrandomized controlled trials (non-RCTs); and cohort studies of pain management techniques in older adults after acute hip fracture.

Conclusions: Nerve blockade seems to be effective in reducing acute pain after hip fracture. Low-level evidence suggests that preoperative traction does not reduce acute pain. Evidence was insufficient on the benefits and harms of many other interventions.

Table 21. Garden Classification of Femoral Neck Fractures

Type	Displacement	Extent	Alignment	Trabeculae	Treatment
I	None	"Incomplete"	Valgus or neutral	Disrupted	Internal fixation to prevent displacement (valgus impacted fracture)
II	None	Complete	Neutral	Aligned	Internal fixation to prevent displacement
III	Partial	Complete	Varus	Disrupted	Young: ORIF Elderly: hemi-/total hip arthroplasty
IV	Complete	Complete	Varus	Disrupted	Young: ORIF Elderly: hemi-/total hip arthroplasty

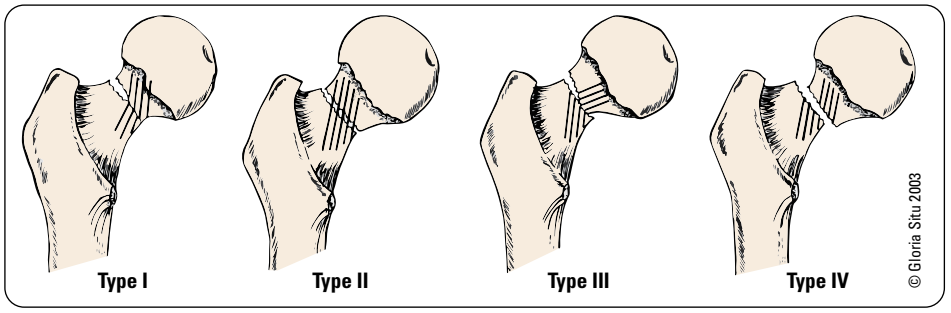

Figure 36. Garden classification of femoral neck fractures

Arthritis of the Hip

Etiology
- OA, inflammatory arthritis, post-traumatic arthritis, late effects of congenital hip disorders, or septic arthritis

Clinical Features
- pain (groin, medial thigh) and stiffness aggravated by activity, relieved with rest in OA
- inflammatory RA: joint pain, morning stiffness >1 h, multiple joint swelling, hand nodules
- decreased ROM (internal rotation is usually lost first)
- crepitus
- leg length discrepancy (secondary to loss of cartilage and/or bone in affected joint)
- ± fixed flexion contracture leading to apparent limb shortening (Thomas test)
- ± Trendelenburg sign and/or gait (limp)

Investigations
- x-ray: weight-bearing views of affected joint
  - OA: joint space narrowing, subchondral sclerosis, subchondral cysts, osteophytes
  - inflammatory (e.g. RA): osteopenia, periarticular erosions, concentric joint space narrowing
- blood work: ANA, RF

Treatment
- non-operative
  - weight reduction, activity modification, physiotherapy, analgesics, anti-inflammatory medications, walking aids
- operative
  - indication: advanced disease with symptoms significantly affecting quality of life
  - realign = osteotomy; replace = arthroplasty; fuse = arthrodesis
- complications with arthroplasty: component loosening, dislocation, HO, thromboembolism, infection, neurovascular injury, limb length discrepancy, persistent limp
- arthroplasty is standard of care in most patients with hip arthritis

Hip Dislocation Post-Total Hip Arthroplasty

- occurs in 1-4% of primary THA and 10-16% of revision THAs
- common indication for early revision
- risk factors: post-traumatic arthritis, revision surgery, substance use, cognitive impairment (dementia), spastic or neuromuscular disease, posterior surgical approach, spinal fusion

Mechanism
- flexion, adduction, and internal rotation (posterior dislocation), or extension and external rotation (anterior dislocation)

Investigations
- x-ray: AP pelvis, AP and lateral views of the hip

Treatment
- non-operative
  - closed reduction and immobilization
- operative
  - indication: recurrent dislocations, associated polyethylene wear, malalignment, hardware failure, or infection
  - revision THA
  - infected hip (infection can cause hip instability)

Complications
- sciatic nerve palsy in 25% (10% permanent)
- HO
- infection

DVT Prophylaxis in Elective THA
(continue 10-35 d postoperative)
DOACs (e.g. rivaroxaban), ASA, fondaparinux, low molecular weight heparin, or warfarin

Femur

Femoral Diaphysis Fracture

Mechanism
- high energy trauma (MVC, fall from height, gunshot wound)
  - pathologic as a result of malignancy, osteoporosis, bisphosphonate use
- in children, can result from low energy trauma (spiral fracture)
  - always consider the possibility of non-accidental trauma

Clinical Features
- shortened, externally rotated leg (if fracture displaced)
- inability to weight-bear
- often open injury, always a Gustilo III (see Table 6, OR10)
- Winquist and Hansen classification

It is important to rule out ipsilateral femoral neck fracture, as they occur in 2-6% of femoral diaphysis fractures and are reportedly missed in 19-31% of cases

Investigations
- x-ray: AP pelvis, AP, and lateral views of the hip, femur, knee

Treatment
- non-operative (paediatric, uncommon in adults)
  - possible indication: non-displaced femoral shaft fractures in patients with significant comorbidities who are non-ambulatory
  - most femoral shaft fractures require fixation as this is a life-threatening injury
- operative
  - ORIF with anterograde IM nail (most common) or retrograde IM nail or with plate and screw fixation
  - external fixation may be used initially (e.g. unstable patients or polytrauma patients)
  - early mobilization and strengthening

Complications
- blood loss
- infection
- fat embolism leading to ARDS
- VTE
- malrotation, leg length discrepancy
- malunion/nonunion

Associated Injuries
- extensive soft tissue damage
- ipsilateral hip dislocation/fracture (2-6%)
- nerve injury

Distal Femoral Fracture

- fractures from articular surface to 5 cm above metaphyseal flare

Mechanism
- direct high energy force or axial loading (may occur due to fall from standing in osteoporotic patients)
- three types: extra articular, partial articular, complete articular

Clinical Features
- extreme pain worse with knee motion
- knee effusion (hemarthrosis)
- neurovascular deficits can occur with displaced fracture

Investigations
- x-ray: AP and lateral views
- ABI if diminished pulses or concern for vascular injury, angiography (ABI <0.9)
- CT: to evaluate the articular surface and degree of comminution

Treatment
- non-operative (uncommon)
  - indication: non-displaced extra-articular fracture, poor surgical candidate
  - hinged knee brace
- operative
  - indication: displaced fracture, intra-articular fracture
- ORIF with plate or retrograde IM nail fixation
- early mobilization

Specific Complications (see *General Fracture Complications*, OR7)
- vascular injury
- nerve injury
- angular deformities/malunion
- post-traumatic arthritis

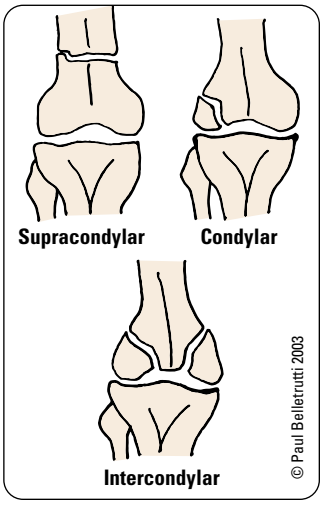

Figure 37. Distal femoral fractures

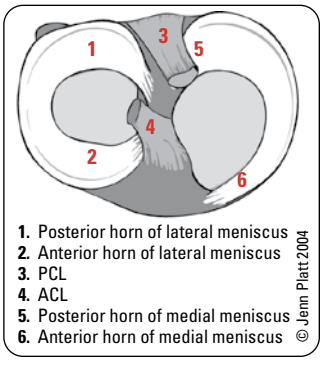

Figure 38. Diagram of the right tibial plateau

Knee

Evaluation of Knee

Common Complaints
- locking, instability, and swelling
  - suggests intra-articular pathology such as a torn meniscus or cruciate ligament injury
- pseudo-locking: limited ROM without mechanical block
  - muscle spasm after injury, arthritis
- painful, audible clicking
  - torn meniscus, cartilage injury, or floating body

Special Tests of the Knee
- **anterior and posterior drawer tests** (Figure 40, OR35)
  - demonstrates torn ACL and PCL, respectively
  - knee flexed at 90°, foot immobilized, hamstrings relaxed
  - anterior subluxation of the tibia (anterior drawer test), suggests ACL injury
  - posterior subluxation of the tibia (posterior drawer test), suggests PCL injury
  - anterior drawer test for ACL: 3.8 positive likelihood ratio, 0.30 negative likelihood ratio
- **Lachman test**
  - demonstrates torn ACL
  - hold knee in 20-30° flexion, stabilizing the distal femur with one hand
  - with contralateral hand, attempt to sublux tibia anteriorly on femur
  - similar to anterior drawer test, more reliable due to less muscular stabilization
  - for ACL: 25.0 positive likelihood ratio, 0.1 negative likelihood ratio
- **pivot shift sign**
  - demonstrates torn ACL
  - start with the knee in extension
  - requires relaxed patient, best performed in patient under spinal or general anesthesia
  - internally rotate foot, slowly flex knee while palpating and applying a valgus force
  - if incompetent ACL, tibia will sublux anteriorly on femur at start of maneuver. During flexion, the tibia will reduce and externally rotate about the femur (the "pivot")

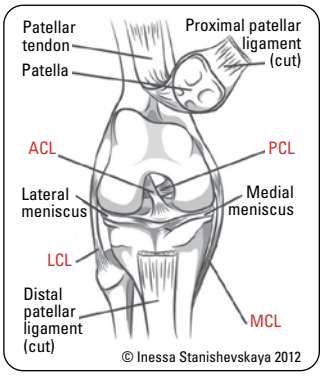

Figure 39. Knee ligament and anatomy

6 Degrees of Freedom of the Knee
- Flexion and extension
- External and internal rotation
- Varus and valgus angulation
- Anterior and posterior glide
- Medial and lateral shift
- Compression and distraction

On physical exam of the knee, do not forget to evaluate the hip

  - reverse pivot shift (start in flexion, externally rotate, apply valgus, and extend knee) suggests posterolateral corner injury
  - composite assessment for ACL: 25.0 positive likelihood ratio, 0.04 negative likelihood ratio
  - composite assessment for PCL: 21.0 positive likelihood ratio, 0.05 negative likelihood ratio
- **posterior sag sign**
  - suggests torn PCL
  - posterior tibial subluxation may lead to false positive anterior drawer sign
  - flex knees and hips to 90°, hold ankles and knees
  - view from the lateral aspect
  - visible posterior tibial sag when compared to uninjured knee suggests PCL injury
- **collateral ligament stress test (varus/valgus instability)**
  - palpate ligament for "opening" of joint space while testing
  - with knee in full extension, apply valgus force to test MCL, apply varus force to test LCL
  - repeat tests with knee in 20° flexion to relax joint capsule
  - opening in 20° flexion suggests MCL injury (valgus force), LCL injury (varus force)
  - opening in 20° of flexion and full extension suggests MCL, cruciate, and joint capsule damage (valgus force)
- **tests for meniscal tear**
  - **joint line tenderness**
    - joint line pain when palpated
    - palpate medial and lateral joint line and observe patient for signs of pain
    - for meniscal tear: 0.9 positive likelihood ratio, 1.1 negative likelihood ratio
  - **crouch compression test**
    - joint line pain when squatting (anterior pain suggests patellofemoral pathology)
  - **McMurray's test**
    - with knee in flexion, palpate joint line for painful pop or click
    - lateral meniscus tear exam: internally rotate foot, apply varus stress, and extend knee
    - medial meniscus tear exam: externally rotate foot, apply valgus stress, and extend knee
    - for meniscal tear: 1.3 positive likelihood ratio, 0.8 negative likelihood ratio

X-Rays

- AP standing, lateral
- skyline: tangential view with knees flexed at 45° to see patellofemoral joint
- 3-foot standing view: useful in evaluating leg length and varus/valgus alignment
- Ottawa Knee Rules (see Emergency Medicine, ER16)

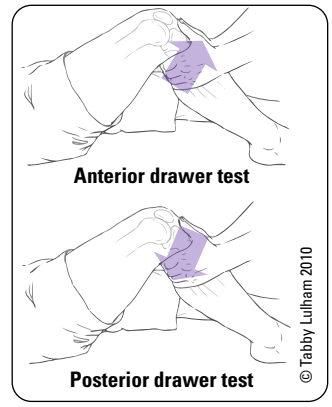

Figure 40. Anterior and posterior drawer test

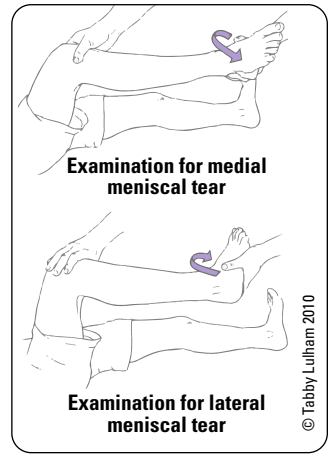

Figure 41. McMurray test

Cruciate Ligament Tears

- ACL tear much more common than PCL tear

Table 22. Comparison of ACL and PCL Injuries

	Anterior Cruciate Ligament	Posterior Cruciate Ligament
Anatomy	Originates from medial wall of lateral femoral condyle, inserts at the anteromedial and posterolateral intercondyloid eminence of the tibial plateau	Originates at the lateral wall of medial femoral condyle, inserts at the posterior intercondyloid eminence of the tibial plateau
Mechanism	Non-contact (more common): sudden deceleration with change of direction or landing maneuver (anterior tibial translation with valgus knee stress) Contact: direct blow to lateral aspect of knee	Non-contact (less common): hyperflexion or hyperextension Contact: sudden posterior displacement of tibia when knee is flexed or hyperextended (e.g. dashboard MVC injury)
History	Audible "pop" Immediate swelling Knee "giving way" Inability to continue activity	Audible "pop" Immediate swelling Pain with push off Cannot descend stairs
Physical	Effusion (hemarthrosis) Posterolateral joint line tenderness Positive anterior drawer Positive Lachmann Pivot shift Test for collateral ligament and meniscal injuries Look for second fracture on x-ray (commonly associated with ACL injuries)	Effusion (hemarthrosis) Anteromedial joint line tenderness Positive posterior drawer Reverse pivot shift Other ligamentous, bony injuries
Treatment	Stable knee with minimal functional impairment: immobilization 2-4 wk with early ROM and strengthening High demand lifestyle: ligament reconstruction	Unstable knee or young person/high-demand lifestyle: ligament reconstruction

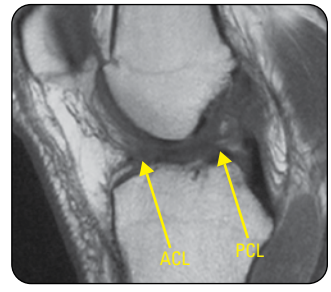

Figure 42. T1 MRI of torn ACL and PCL

Collateral Ligament Tears

Mechanism
- valgus force to knee = MCL tear
- varus force to knee = LCL tear

Clinical Features
- swelling/effusion
- tenderness above and below joint line medially (MCL) or laterally (LCL)
- joint laxity with varus (LCL) or valgus (MCL) stress tests
  - laxity with endpoint suggests partial tear
  - laxity with no endpoint suggests a complete tear
- test for other injuries (e.g. O'Donoghue's unhappy triad), common peroneal nerve injury

Investigations
- x-ray: AP and lateral views of the knee; MRI

Treatment
- non-operative
  - partial tear: immobilization x 2-4 wk with early ROM and strengthening
  - complete tear: immobilization at 30° flexion
- operative
  - indication: multiple ligamentous injuries
  - surgical repair of ligaments

O'Donoghue's Unhappy Triad
- ACL rupture
- MCL rupture
- Meniscal damage (medial and/or lateral)

Meniscal Tears

- medial tear much more common than lateral tear

Mechanism
- twisting force on knee when it is partially flexed (e.g. stepping down and turning)
- requires moderate trauma in young person, but only mild trauma in elderly due to degeneration

Clinical Features
- immediate pain, difficulty weight-bearing, instability, and clicking
- increased pain with squatting and/or twisting
- effusion (hemarthrosis) with insidious onset (24-48 h after injury)
- joint line tenderness medially or laterally
- locking of knee (if portion of meniscus mechanically obstructing extension)

Investigations
- MRI, arthroscopy

Treatment
- non-operative
  - indication: not locked, degenerative tear in the presence of osteoarthritis
  - ROM and strengthening (NSAIDs)
- operative
- indication: locked knee is a surgical emergency (i.e. patient cannot fully extend knee, due to mechanical block) or failed non-operative treatment
  - arthroscopic repair/partial meniscectomy generally indicated for younger patients with traumatic/non-degenerative meniscus pathology

Meniscal repair may be performed in select patients if tear is peripheral with good vascular supply, is a longitudinal tear and 1-4 cm in length
Partial meniscectomy may be performed when tears are not amenable to repair (complex, degenerative, radial)

Tissue Sources for ACL Reconstruction
- Hamstring autograft
- Middle 1/3 patellar tendon (bone-patellar-bone autograft)
- Allograft (e.g. cadaver)

Popliteal Cysts

- synovial fluid-filled mass located in the popliteal fossa (i.e. Baker's cyst)

Etiology
- classified as primary (distension of the bursa with no communication to joint) or secondary (communication between bursa and joint, bursa fills with articular fluid)
- primary cysts are usually congenital in children, while secondary are acquired from traumatic injury or degenerative/inflammatory joint disease in adults

Clinical Features
- usually asymptomatic bulge on the posterior aspect of the knee
- usually located between the semimembranosus and medial head of gastrocnemius
- may cause local tightness, restricted range of motion or posterior knee pain
- symptoms may worsen with physical activity
- for secondary popliteal cysts, symptoms are more associated with the underlying condition of the knee

Investigations
- clinical diagnosis is often sufficient
- ultrasonography can be used to identify cyst and its relation to adjacent soft tissue structures
- knee x-ray to assess for joint abnormalities that may be associated with the cyst
- MRI allows for clearest visualization but this is only indicated to plan for surgery, when an underlying knee pathology such as a meniscal tear is suspected, or when the diagnosis is uncertain after ultrasonography

Treatment
- asymptomatic cysts do not require treatment
- non-operative
  - indication: initial treatment for symptomatic secondary popliteal cysts
  - identify and treat underlying cause
  - rest, NSAIDs, cold packs for symptomatic treatment
  - image guided aspiration and intra-articular steroid injection may offer temporary relief

Quadriceps/Patellar Tendon Rupture

Mechanism
- sudden forceful contraction of quadriceps during an attempt to decelerate
- eccentric loading of the extensor mechanism, usually with the foot planted and the knee slightly bent
  - DM, SLE, RA, steroid use, renal failure on dialysis
- more common in obese patients with pre-existing degenerative changes in tendon

Clinical Features
- inability to extend knee or weight-bear
- tenderness and/or palpable gap at rupture site
- possible audible "pop"
- patella in lower or higher position with palpable gap above or below patella, respectively
- may have an effusion

Patella alta = high riding patella
Patella baja = low riding patella

Investigations
- ask patient to perform straight leg raise (unable to with complete rupture, although may be inhibited by pain, if unclear, can reassess in 10 d)
- knee x-ray to rule out patellar fracture, MRI to distinguish between complete and partial tears
- lateral view: patella alta with patella tendon rupture, patella baja with quadriceps tendon rupture

Treatment
- non-operative
  - indication: incomplete tears with preserved extension of knee
  - immobilization in brace, followed by progressive physiotherapy
- operative
  - indication: complete ruptures with loss of extensor mechanism function
- early surgical repair: better outcomes compared with delayed repair (>6 wk post-injury)
- delayed repair complicated by quadriceps contracture, patella migration, and adhesions

Dislocated Knee

Mechanism
- high energy trauma more common (i.e. MVC) or low energy (sport related, obesity)
- by definition, caused by tears of multiple ligaments

Schenck Classification
Type 1
Single ligament injury (ACL or PCL)
Type 2
Injury to ACL and PCL
Type 3
Injury to ACL, PCL, and either MCL or LCL
Type 4
Injury to ACL, PCL, MCL, LCL
Type 5
Multiligamentous injury with periarticular fracture

Clinical Features
- knee instability
- effusion
- pain
- ischemic limb

Classification
- Kennedy classification (based on direction of tibial displacement) classified by relation of tibia with respect to femur
  - anterior, posterior, lateral, medial, rotary
- Schenck classification (based on pattern of ligamentous injury)

Investigations
- x-ray: AP and lateral
  - associated radiographic findings may include extensor mechanism injury, tibial plateau fracture dislocations, proximal fibular fractures, and/or avulsion of fibular head
- assessment of NVS:
  - ABI (abnormal if <0.9)
  - arteriogram or CT angiogram if abnormal vascular exam (such as abnormal pedal pulses)
  - detailed neurologic assessment, paying close attention to the peroneal nerve (foot drop is common)

Treatment
- urgent closed reduction
  - can be complicated by interposed soft tissue (posterolateral variant)
- assessment and management of neurovascular injuries
- emergent operative repair if vascular injury, open fracture or dislocation, irreducible dislocation, or compartment syndrome
- ligament reconstruction to restore knee stability is typically performed in a staged fashion
- comprehensive physiotherapy

Specific Complications
- high incidence of associated injuries (tibia/fibula fracture, extensor mechanism injury)
- popliteal artery injury
- peroneal nerve injury
- capsular tear
- chronic: instability, stiffness, post-traumatic arthritis

Patella

Patellar Fracture

Mechanism
- direct impact injury: fall, MVC (e.g. dashboard)
- indirect trauma: rapid knee flexion against contracted quadriceps

Clinical Features
- marked tenderness
- inability to extend knee or straight leg raise
- proximal displacement of patella
- patellar deformity
- ± effusion/hemarthrosis

Investigations
- x-rays: AP, lateral, skyline
- do not confuse with bipartite patella: congenitally unfused ossification centers with smooth margins on x-ray at superolateral corner (most often)

Treatment
- non-operative
  - indication:
    - non or minimally displaced (step-off <2-3 mm and fracture gap <1-4 mm)
    - intact extensor mechanism
- straight leg immobilization 1-4 wk with removable brace/splint, weight bearing as tolerated
- progress in flexion after 2-3 wk
- physiotherapy: quadriceps strengthening when pain has subsided
- operative
  - indication:
    - >2 mm articular step-off, >3 mm fragment separation, comminuted, disrupted extensor mechanism, open fracture
    - ORIF, if comminuted may require partial/complete patellectomy
- goal: restore extensor mechanism with maximal articular congruency

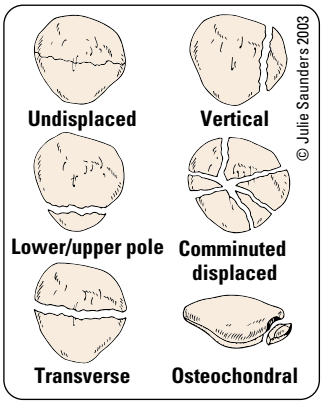

Figure 43. Types of patellar fractures

Complications
- Symptomatic hardware
- Loss of reduction
- Osteonecrosis (proximal fragment)
- Hardware failure
- Knee stiffness
- Nonunion
- Infection

Patellar Dislocation

Mechanism
- usually a non-contact twisting injury with knee extended, externally rotated tibia and fixed foot
- lateral displacement of patella after contraction of quadriceps at the start of knee flexion in an almost straight knee joint
- direct blow (e.g. knee/helmet to knee collision)

J-sign: Associated with patella alta; increased lateral translation in extension which pops into the patellofemoral groove as the patella engages the trochlea early in flexion

Risk Factors
- 2nd-3rd decade of life, female
- Q-angle (quadriceps angle) ≥15° (males) ≥20° (females)
  - femoral anteversion, genu valgum, external tibial torsion/pronated feed
- high-riding patella (patella alta)
- weak vastus medialis
- ligamentous laxity (Ehlers-Danlos)

Clinical Features
- knee catches or gives way with walking
- severe pain, tenderness anteromedially from rupture of capsule
- weak knee extension or inability to extend leg unless patella reduced
- positive patellar apprehension test
  - passive lateral translation results in guarding and patient apprehension
- often recurrent, self-reducing
- concomitant MCL injury
- J-sign

Investigations
- x-rays: AP, lateral, and skyline views of the knee
- check for fracture of medial patella (most common) and lateral femoral condyle

Treatment
- non-operative first
  - closed reduction
  - NSAIDs, activity modification, and physical therapy
  - short-term immobilization for comfort, then 6 wk controlled motion
  - progressive weight bearing and isometric quadriceps strengthening
- operative
  - indication: if recurrent or if loose bodies present
  - surgical tightening of medial capsule and release of lateral retinaculum, possible medial patellofemoral ligament (MPFL) reconstruction, possible tibial tuberosity transfer, or proximal tibial osteotomy

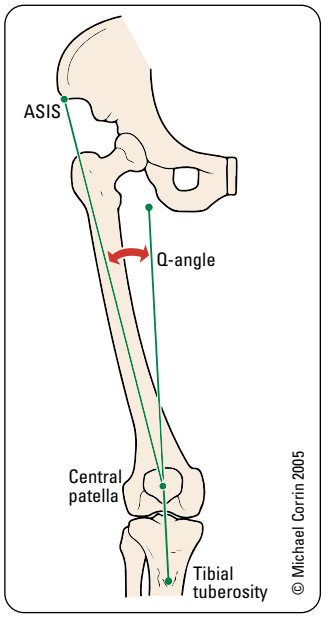

Figure 44. Q-angle
The angle between a vertical line through the patella and tibial tuberosity and a line from the ASIS to the middle patella; the larger the angle, the greater the amount of lateral force on the knee (normal <20°)

Patellofemoral Syndrome (Chondromalacia Patellae)

- syndrome of anterior knee pain associated with idiopathic articular changes of patella

Risk Factors
- malalignment causing patellar maltracking (Q-angle ≥20°, genu valgus)
- female > male, physically active <40 y/o
- excessive knee strain (athletes, especially running and weight training)
- recurrent patellar dislocation, ligamentous laxity, post-trauma
- deformity of patella or femoral groove

Mechanism
- softening, erosion, and fragmentation of articular cartilage, predominantly medial aspect of patella

Clinical Features
- diffuse pain in peri- or retropatellar area of knee (major symptom)
  - exacerbated by prolonged sitting (theatre sign), strenuous athletic activities, stair climbing, squatting, or kneeling
- insidious onset and vague in nature
- sensation of instability, pseudolocking
- pain with compression of patella with knee ROM or with resisted knee extension
- swelling rare, minimal if present
- palpable crepitus

Pain with firm compression of patella into medial femoral groove is pathognomonic of patellofemoral syndrome

Investigations
- x-ray: AP, lateral, and skyline views of the knee – may find chondrosis, lateral patellar tilt, patella alta/baja, or shallow sulcus
- CT: patellofemoral alignment, rule out fracture
- MRI: best to assess articular cartilage

Treatment
- non-operative
  - continue non-impact activities; rest and rehabilitation
  - NSAIDs
  - physiotherapy: vastus medialis, core, and hip strengthening
- operative
  - indication: failed non-operative treatment
  - arthroscopic shaving/debridement
  - lateral release of retinaculum
  - patellar realignment (e.g. anterior tubercle elevation)

Tibia

Tibial Plateau Fracture

Mechanism
- varus/valgus load ± axial loading (e.g. fall from height)
- femoral condyles driven into proximal tibia
- can result from minor trauma in those with osteoporosis

Clinical Features
- frequency: lateral > bicondylar > medial
- medial fractures require higher energy – often have concomitant vascular injuries
- knee effusion, swelling
- inability to bear weight
- risk of compartment syndrome, ACL injury, meniscal tears, and vascular injuries
- Schatzker classification

Schatzker Classification

Type	Description
I	Lateral plateau split fracture
II	Lateral split-depressed fracture
III	Lateral pure depression fracture
IV	Medial plateau fracture
V	Bicondylar plateau fracture
VI	Bicondylar with metaphyseal/diaphyseal disassociation

Investigations
- x-ray: AP, lateral, and oblique views
- CT: preoperative planning, identify articular depression and comminution
- ABI if any differences in pulses between extremities

Treatment
- non-operative
  - indication: # depression is <3 mm
  - protected weight bearing with immobilization in a splint for 8-12 wk with early progressive ROM
- operative
  - indication: articular stepoff >3 mm, condylar widening >5 mm, open #s, neurovascular injury, significant varus/valgus instability (>15°)
  - ORIF often requiring bone grafting to elevate depressed fragment

Specific Complications (see *General Fracture Complications*, OR7)
- post-traumatic OA
- ligamentous injuries
- meniscal lesions
- AVN

Tibial Shaft Fracture

- most common long bone fracture and open fracture

Mechanism
- low energy pattern: torsional injury
- high energy: including MVC, falls, sporting injuries

Clinical Features
- pain, inability to weight bear, deformity
- open vs. closed
- neurovascular compromise

Investigations
- x-ray: full length AP and lateral views
  - AP, lateral, and oblique views of ipsilateral knee and ankle

Figure 45. Tibial shaft fracture treated with IM nail and screws

Tibial shaft fractures have high incidence of compartment syndrome and are often associated with soft tissue injuries

Treatment
- non-operative
  - indication: closed and minimally displaced or adequate closed reduction
  - long leg cast x 6-8 wk, convert to functional (patellar tendon bearing) brace after
- operative
  - indication: displaced or open
  - if displaced and closed: ORIF with IM nail, plate and screws, or external fixator
  - if open: antibiotics, I&D, external fixation or IM nail, and vascularized coverage of soft tissue defects

Specific Complications (see *General Fracture Complications*, OR7)
- significant incidence of compartment syndrome and neurovascular injury
- knee pain (>50% anterior knee pain with infrapatellar IM nailing)
- malunion, nonunion
- lack of soft tissue coverage secondary to open fracture may require further surgery for muscle flap coverage and can lead to poor outcome

Ankle

Evaluation of Ankle and Foot Complaints

Special Tests
- anterior drawer: examiner stabilizes the tibia with one hand and attempts to displace the foot anteriorly with the contralateral hand with the ankle held in neutral or plantar flexion
- talar tilt: foot is stressed in inversion and angle of talar rotation is evaluated

X-Ray
- AP, mortise, and lateral views
- mortise view: ankle at 15° of internal rotation
  - gives true view of ankle joint
  - joint space should be symmetric with no talar tilt
- Ottawa Ankle and Foot Rules should guide x-ray use (see Emergency Medicine, ER16); nearly 100% sensitivity
- ± CT to better characterize fractures

Ankle Fracture

Mechanism
- pattern of fracture depends on the position of the ankle when trauma occurs
- classification systems
  - Danis-Weber: based on location of main fibular fracture line relative to the syndesmosis
  - Lauge-Hansen: based on foot position and direction of applied stress/force

Treatment
- non-operative
  - indication: non-displaced, Danis-Weber Type A, and some isolated Danis-Weber Type B
  - NWB in below knee cast, or weight bearing as tolerated in walking boot
- operative
  - indications
    - fracture-dislocation: restore vascularity, minimize articular injury, reduce pain and skin pressure
    - most Danis-Weber Type B, and all Type C
    - any talar displacement
    - displaced isolated medial or lateral malleolar fracture
    - trimalleolar (medial, posterior, lateral) fractures
    - displaced and large posterior malleolar fractures
    - persistent medial clear space widening despite attempt at closed reduction and immobilization
    - open fracture/open joint injury
  - ORIF with plates and screws

Complications
- risk of poor wound healing and deep infections (up to 20%) in patients with DM, particularly if concomitant peripheral neuropathy
- postoperative stiffness
- malunion, nonunion
- post-traumatic arthritis

Danis-Weber Classification
- Based on level of fibular fracture relative to syndesmosis
- Type A (infra-syndesmotic)
- Pure inversion injury, tibiofibular syndesmosis remains intact
- Avulsion of lateral malleolus below plafond or torn calcaneofibular ligament
- ± shear fracture of medial malleolus
- Type B (trans-syndesmotic)
- External rotation and eversion (most common)
- ± avulsion of medial malleolus or rupture of deltoid ligament
- Spiral fracture of lateral malleolus starting at plafond
- Type C (supra-syndesmotic)
- Pure external rotation
- Avulsion of medial malleolus or torn deltoid ligament
- ± posterior malleolus avulsion with posterior tibio-fibular ligament
- Fibular fracture is above plafond
- Frequently tears syndesmosis

Ottawa Ankle and Foot Rules
(see Emergency Medicine, ER16)
X-rays are only required if:
Pain in the malleolar zone AND any of: bony tenderness over posterior or tip of lateral malleolus; OR bony tenderness over posterior or tip of medial malleolus; OR inability to weight bear both immediately after injury and in the ER

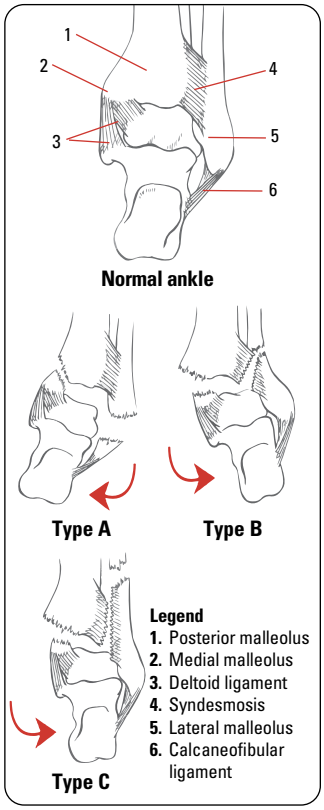

Figure 46. Ring principle of the ankle and Danis-Weber classification

Ankle Ligamentous Injuries

Medial Ligament Complex (deltoid ligament)
- eversion injury
- usually avulses medial or posterior malleolus and strains syndesmosis

Lateral Ligament Complex
(anterior talofibular, calcaneofibular, posterior talofibular)
- inversion injury, >90% of all ankle sprains
- ATF most commonly and severely injured if ankle is plantarflexed
- swelling and tenderness anterior to lateral malleolus
- ++ ecchymosis
- positive ankle anterior drawer
- may have significant medial talar tilt on inversion stress x-ray

Treatment
- non-operative
  - microscopic tear (Grade I)
    - rest, ice, compression, elevation
  - macroscopic tear (Grade II)
    - strap ankle/aircast for up to a few weeks, should not interfere with early rehabilitation; NSAIDs
    - physiotherapy: strengthening and proprioceptive retraining
  - complete tear (Grade III)
    - below knee walking cast x 4-6 wk (controversial & variable); NSAIDs
    - physiotherapy: strengthening and proprioceptive retraining
    - surgical intervention may be required if chronic symptomatic instability develops

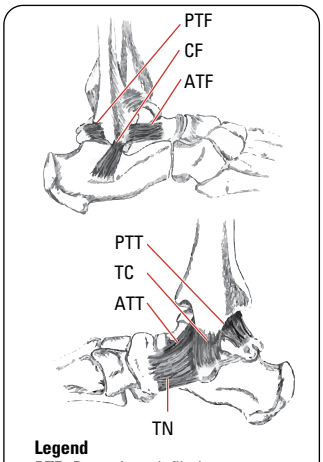

Figure 47. Ankle ligament complexes

With a history of significant trauma from axial loading of lower limb, always consider spinal injuries, femoral neck, tibial plateau, and talar/calcaneal fractures

Foot

Talar Fracture

Mechanism
- forced dorsiflexion with axial load, commonly from MVC or fall from height
- 60% of talus covered by articular cartilage; fractures often intra-articular
- talar neck is most common fracture of talus (50%)
- tenuous blood supply runs distal to proximal along talar neck
  - high-risk of AVN with displaced fractures

Investigations
- x-ray: AP, lateral, and Canale views (maximum equinus, 15° pronated) of the foot
- CT to better characterize fracture and assess for ipsilateral foot injuries (up to 88% incidence)
- MRI not helpful acutely, but can clearly define extent of AVN during follow up

Treatment
- non-operative
  - indication: non-displaced
  - emergent reduction in ER, below-knee cast 8-12 wk (NWB first 6 wk)
- operative
  - indication: displaced
  - ORIF

Complications
- AVN (~30% risk of osteonecrosis)
- malunion/nonunion
- post-traumatic arthritis (subtalar most common)

Calcaneal Fracture

- most common tarsal fracture

Mechanism
- high energy axial loading: fall from height onto heels, MVA
- 10% of fractures associated with compression fractures of thoracic or lumbar spine (rule out spine injury)
- 75% are intra-articular and 10% are bilateral

Calcaneal Fracture Treatment Principles
- Avoid wound complications (10-25%)
- Restore articular congruity
- Restore normal calcaneal width and height
- Maximum functional recovery may take longer than 12 mo

Clinical Features
- marked swelling, pain, inability to weight bear, bruising on heel/sole
- wider, shorter, flatter heel when viewed from behind
  - may have apparent varus deformity

Investigations
- x-rays: AP, lateral, and oblique foot (mandatory views); Broden view, Harris view, or AP ankle (optional)
  - loss of Bohler's angle, double-density sign
- CT: gold-standard, assess intra-articular extension

Treatment
- closed vs. open reduction is controversial
- NWB cast x 6-12 wk with early ROM and strengthening

Haglund Deformity: an enlargement of the posterior-superior tuberosity of the calcaneus

Achilles Tendonitis

Mechanism
- chronic inflammation from activity or poor-fitting footwear
- may develop painful heel bumps (i.e. retrocalcaneobursitis or Haglund deformity)

Clinical Features
- posterior heel pain, swelling, burning, stiffness
- thickened tendon, palpable bump

Investigations
- x-ray: lateral, evaluate bone spur and calcification
- U/S, MRI can assess degenerative change

Treatment
- non-operative
  - rest, NSAIDs, activity and shoe wear modification (orthotics, open back shoes)
  - heel sleeves and pads are mainstay of non-operative treatment
  - gentle gastrocnemius-soleus stretching, eccentric training with physical therapy, deep tissue calf massage
  - shockwave therapy in chronic tendonitis
  - avoid steroid injections (risk of Achilles tendon rupture)
- operative
  - open of arthroscopic debridement of Hagelung lesion

The most common site of Achilles tendon rupture is 2-6 cm from its insertion where the blood supply is the poorest

Achilles Tendon Rupture

Mechanism
- sudden forced plantar flexion, violent dorsiflexion when plantar flexed
- loading activity, stop-and-go sports (e.g. squash, tennis, basketball)
- secondary to chronic tendonitis, steroid injection, fluoroquinolone antibiotics

Clinical Features
- audible "pop," sudden pain with push-off movement
- pain or weakness/inability to plantarflex
- palpable gap
- apprehensive toe off when walking
- Thompson test: with patient prone, squeeze calf, normal response is plantar flexion
  - no passive plantarflexion is positive test = ruptured tendon

Investigations
- x-ray: rule out other pathology
- U/S or MRI: differentiate between partial vs. complete ruptures

Treatment
- non-operative
  - indication: low functional demand (level 1 evidence suggests no difference in re-rupture rates between operative and non-operative management with functional rehabilitation)
  - functional bracing/casting in resting equinus (plantar flexion), with functional rehabilitation x 8-12 wk
- operative
  - indication: high functional demand
  - surgical repair, followed by functional rehabilitation x 8-12 wk

Complications of Achilles Tendon Rupture
- Infection/ wound healing complications (operative management)
- Sural nerve injury (operative management)
- Re-rupture: surgical repair decreases likelihood of re-rupture compared to non-operative management

Plantar Fasciitis

Definition
- inflammation of plantar aponeurosis at calcaneal origin
- common in athletes (especially runners, dancers)
- also associated with obesity, DM, inflammatory arthropathies

Mechanism
- repetitive strain injury causing microtears and inflammation of plantar fascia

Clinical Features
- insidious onset of heel pain, often when getting out of bed, and stiffness
- intense pain when walking from rest that subsides with ambulation; worse at end of day after prolonged standing
- tenderness to palpation at medial tuberosity of calcaneus
- pain with toe dorsiflexion (stretches fascia) and palpation of fascia from heel to forefoot

Investigations
- x-ray to rule out fractures, may show plantar heel spur
- spur is secondary to inflammation, not the cause of pain

Treatment
- non-operative
  - pain control and stretching programs are first-line
  - rest, ice, NSAIDs, steroid injection
  - physiotherapy: Achilles tendon and plantar fascia stretching, extracorporeal shockwave therapy
  - orthotics with heel cup – to counteract pronation and disperse heel strike forces
- operative
  - very rarely indicated
  - when performed, includes endoscopic release of fascia

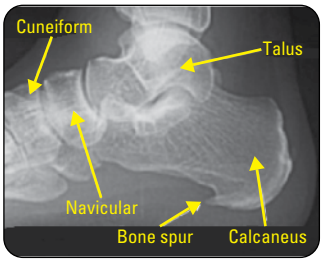

Figure 48. X-ray of bony heel spur

Surgical vs. Nonsurgical Methods for Acute Achilles Tendon Rupture: A Meta-Analysis of Randomized Controlled Trials
J Foot Ankle Surg Am 2018 Nov - Dec; 57(6): 1191-1199
Purpose: To compare surgical treatment and conservative treatment of acute Achilles tendon rupture.
Methods: A meta-analysis was performed looking at randomized trials comparing surgical with nonsurgical treatment or comparing different surgical treatments of Achilles tendon rupture.
Results: 10 randomized clinical trials with a total of 934 randomized patients were included. Patients in the non-surgical group had a higher re-rupture rate than patients in the surgical group. However, re-rupture rates were equivalent (P = .08) if an early range of motion exercises protocol was performed. Lower incidence of complications (excluding re-rupture) was found in non-surgical patients.
Conclusions: Non-surgical treatment for acute Achilles tendon rupture is preferred if a functional rehabilitation protocol with early range of motion is possible. If not, surgical treatment should be considered because of the lower rate of re-rupture.

Bunions (Hallux Valgus)

Definition
- bony deformity characterized by medial displacement of first metatarsal and lateral deviation of hallux

Mechanism
- many associated deformities in foot from altered mechanics
- valgus alignment of 1st MTP (hallux valgus), loose medial and tight lateral joint capsule, adductor hallucis becomes a deforming force
- formation of a reactive exostosis and thickening of the skin creates a bunion
- associated with poor-fitting footwear (high heel and narrow toe box)
- can be hereditary (70% have family history)
- more frequent in women

Clinical Features
- painful bursa over medial eminence of 1st MT head
- pronation (rotation inward) of great toe
- numbness over medial aspect of great toe

Investigations
- x-ray: standing AP, lateral, and oblique views; sesamoid can be helpful

Treatment
- indications: painful corn or bunion, overriding 2nd toe
- non-operative (first-line)
  - properly fitted shoes (low heel) and toe spacer
- operative: persistent symptoms, goal is to restore normal anatomy, not cosmetic reasons alone
  - osteotomy with realignment of 1st MTP joint
  - arthrodesis

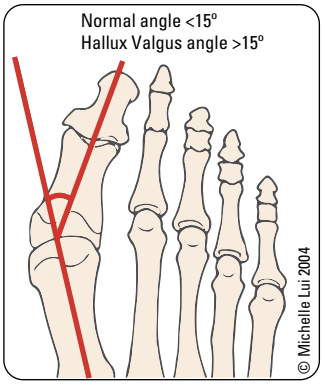

Figure 49. Hallux valgus

Metatarsal Fracture

- use Ottawa Foot Rules to determine need for x-ray

Table 23. Types of Metatarsal Fractures

Fracture Type	Mechanism	Clinical Features	Treatment
Avulsion of Base of 5th MT	Sudden inversion followed by contraction of peroneus brevis	Tender base of 5th MT	Conservative management
Proximal Shaft of 5th MT (Jones Fracture)	Stress injury	Painful over base of 5th MT	*NWB BK cast x 6-8 wk
Shaft 2nd, 3rd MT (March Fracture)	ORIF if athlete, displacement, or skin tenting	Painful shaft of 2nd or 3rd MT	Symptomatic
1st MT	Trauma	Painful 1st MT	ORIF if displaced otherwise *NWB BK cast x 3 wk then walking cast x 2 wk
Tarso-MT Fracture – Dislocation (Lisfranc Fracture)	Fall onto plantar flexed foot or direct crush injury	Pain over base of 2nd MT Swelling over midfoot Inability to bear weight	ORIF or arthrodesis if displaced otherwise cast immobilization x 8-12 wk

*NWB BK = Non weight bearing, below knee

Ottawa Ankle and Foot Rules
(see Emergency Medicine, ER16)
X-rays only required if:
Pain in the midfoot zone AND any of: bony tenderness over the navicular or base of the fifth metatarsal; OR inability to weight bear both immediately after injury and in the ER

Paediatric Orthopaedics

Fractures in Children

- type of fracture
  - thicker, more active periosteum results in paediatric-specific fractures: greenstick (one cortex), torus (i.e. 'buckle', impacted cortex) and plastic (bowing)
  - distal radius fracture most common in children (phalanges second), the majority are treated with closed reduction and casting
- epiphyseal growth plate
  - weaker part of bone, susceptible to injuries
  - plate often mistaken for fracture on x-ray and vice versa (x-ray opposite limb for comparison), especially in elbow
  - tensile strength of bone < ligaments in children, therefore clinician must be confident that fracture and/or growth plate injury have been ruled out before diagnosing a sprain
  - intra-articular fractures have worse consequences in children because they usually involve the growth plate, and may affect future bone growth
- anatomic reduction
  - gold standard with adults
  - may accept greater angular deformity in children as remodeling minimizes deformity at skeletal maturity
- time to heal
  - shorter in children
- always be aware of the possibility of child abuse
  - ensure stated mechanism is compatible with injury presentation
  - high index of suspicion with fractures in non-ambulating children (<1 yr); look for other signs, including x-ray evidence of healing fractures at different sites and different stages of healing
  - common suspicious fractures in children: metaphyseal corner fracture (hallmark of non-accidental trauma), femur fracture <1 y/o, humeral shaft <3 y/o, sternal fractures, posterior rib fractures, spinous process fractures

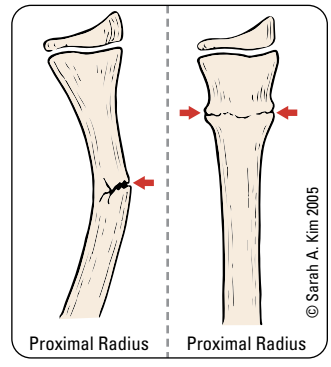

Figure 50. Greenstick (left) and torus (right) fractures

Greenstick fractures are easy to reduce but can redisplace while in cast due to intact periosteum

Stress Fractures

Mechanism

- insufficiency fracture
  - normal or physiologic stress applied to a weak or structurally deficient bone
- fatigue fracture
  - repetitive, excessive force applied to normal bone
- most common in adolescent athletes
- common in tibia, calcaneus, and metatarsals

Diagnosis

- localized pain and tenderness over the involved bone
- plain films may not show fracture initially
- bone scan positive in 12-15 d, MRI demonstrates abnormal edema

Treatment
- rest from strenuous activities to allow remodeling (can take several months)
- protected weight bearing
- splinting/Aircast optional

Physeal Injury

Table 24. Salter-Harris Classification of Epiphyseal Injury

SALT(E)R–Harris Type	Description	Treatment
I (Straight through; Stable)	Transverse through growth plate	Closed reduction and cast immobilization (except SCFE – ORIF); heals well, 95% do not affect growth
II (Above)	Through metaphysis and along growth plate	Closed reduction and cast if anatomic; otherwise ORIF
III (Below)*	Through epiphysis to plate and along growth plate	Anatomic reduction by ORIF to prevent growth arrest, avoid fixation across growth plate
IV (Through and through)*	Through epiphysis and metaphysis	Closed reduction and cast if anatomic; otherwise ORIF
V (Ram)*	Crush injury of growth plate	Cast immobilization (operative management is rarely indicated): high incidence of growth arrest

* Types III – V are more likely to cause growth arrest and progressive deformity

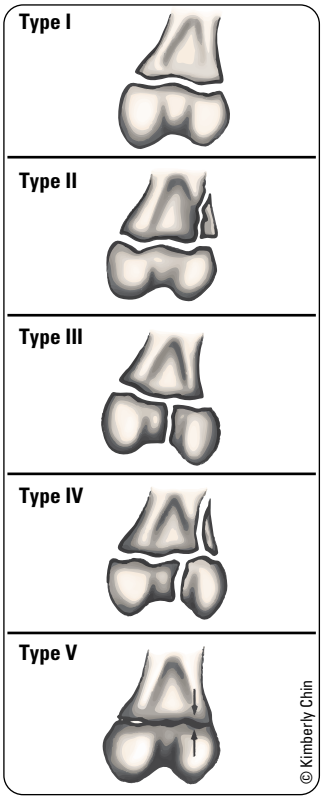

Figure 51. Salter-Harris Classification of Epiphyseal Injury

Slipped Capital Femoral Epiphysis

- most common adolescent hip disorder, peak incidence at pubertal growth spurt

Definition
- type I Salter-Harris epiphyseal injury at proximal hip with anterosuperior displacement of the metaphysis relative to the epiphysis (remains in the acetabulum)

Etiology
- multifactorial
  - genetic: autosomal dominant, Black children at highest risk
  - cartilaginous physis hypertrophies too rapidly under growth hormone effects
  - sex hormone secretion, which stabilizes physis, has not yet begun
  - overweight: mechanical stress
  - trauma: causes acute slip
- risk factors: obesity (#1 factor), male, hypothyroid (risk of bilateral involvement), growth hormone deficiency, previous radiation to hip region, renal osteodystrophy

Clinical Features
- acute: sudden, severe pain with limp, less than 3 wk duration
- chronic: typically groin and anterior thigh pain, may present with knee pain
  - positive Trendelenburg sign on affected side, due to weakened gluteal muscles
- can be associated with knee pain due to activation of the medial obturator nerve
- restricted internal rotation, abduction, flexion
  - Drehmann sign: obligatory external rotation during passive flexion of hip
- Loder classification: stable vs. unstable (provides prognostic information)
  - stable = able to bear weight, with or without crutches (risk of osteonecrosis <10%)
  - unstable = unable to ambulate even with crutches (high-risk of osteonecrosis, between 24-47%)

Bilateral involvement occurs in about 25%

Klein's Line
On AP view, line drawn along superolateral border of femoral neck should cross at least a portion of the femoral epiphysis. If it does not, suspect SCFE

Investigations
- x-ray: AP, frog-leg lateral radiographs both hips
  - posterior and medial slip of epiphysis
  - disruption of Klein's line
  - AP view may be normal or show widened/lucent growth plate compared with opposite side

Treatment
- operative: percutaneous in-situ fixation without reduction (reduction is highly controversial)
- consider prophylactic fixation of contralateral hip in high-risk patients

Complications
- AVN, chondrolysis (loss of articular cartilage, resulting in narrowing of joint space), pin penetration, premature OA, loss of ROM, contralateral SCFE

Developmental Dysplasia of the Hip

Definition
- abnormal development of hip, resulting in shallow acetabulum (dysplasia), displacement with some remaining contact between the articular surfaces (subluxation), or complete displacement of the joint (dislocation)
- most common orthopaedic disorder in newborns

Etiology
- due to ligamentous laxity, muscular underdevelopment, and abnormal shallow slope of acetabular roof
- spectrum of conditions
  - dislocated femoral head completely out of acetabulum
  - dislocatable head in socket
  - head subluxates out of joint when provoked
  - dysplastic acetabulum, more shallow, and more vertical than normal

Physical Exam
- diagnosis is clinical
  - limited abduction of the flexed hip (<60°)
  - affected leg shortening results in asymmetry in skin folds and gluteal muscles, wide perineum
  - Barlow's test demonstrates whether hips are dislocatable
    - flex hips and knees to 90° and grasp thigh
    - fully adduct hips, push posteriorly to try to dislocate hips, feeling for a distinct clunk
  - Ortolani's test demonstrates whether hips are reducible
    - initial position as above but try to reduce hip with fingertips during abduction
    - positive test: palpable clunk is felt (not heard) if hip is reduced
  - Trendelenburg test and gait useful if older (>2 yr)
  - Galeazzi's sign
    - knees at unequal heights when hips and knees flexed
    - appearance of a shorter femur (lower knee) on affected side
    - difficult test if child <1 yr

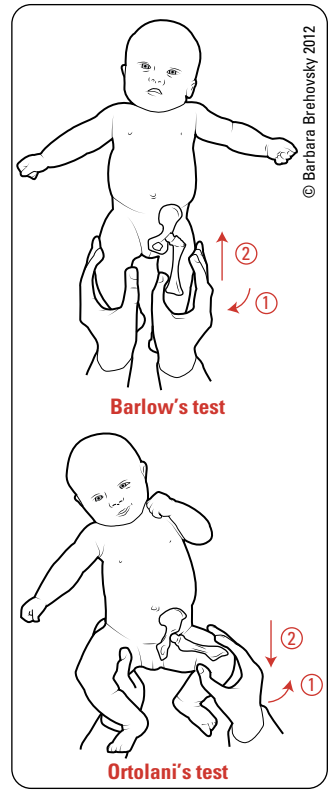

Figure 52. Barlow's test and Ortolani's test

Investigations
- U/S in first few months to view cartilage (bone is not calcified in newborns until 4-6 mo)
- follow-up radiograph after 3 mo
- x-ray signs (at 4-6 mo): false acetabulum, acetabular index >25°, broken Shenton's line, femoral neck above Hilgenreiner's line (horizontal line through right and left triradiate cartilage), ossification centre outside of inner lower quadrant (quadrants formed by intersection of Hilgenreiner's and Perkin's lines)

Treatment
- 0-6 mo: reduce hip using Pavlik harness to maintain abduction and flexion
- 6-18 mo: reduction under GA, hip spica cast x 2-3 mo (if Pavlik harness fails)
- 18 mo-2 yr: open reduction with spica casting
- >2 yr: pelvic and/or femoral osteotomy

Complications
- redislocation, inadequate reduction, stiffness
- AVN of femoral head may be seen at any point in treatment; due to impingement of medial circumflex femoral artery with severe abduction and flexion secondary to prolonged Pavlik harness or spica cast treatment

5 Fs that Predispose to Developmental Dysplasia of the Hip
Family history
Female
Frank breech
First born
Le**F**t hip

Legg-Calvé-Perthes Disease (Coxa Plana)

Definition
- idiopathic AVN of femoral head, presents at 4-8 yr of age
- 12% bilateral, M:F=5:1, 1/1200
- associations
  - family history of Legg-Calve-Perthes Disease
  - low birth weight
  - abnormal pregnancy/delivery
  - ADHD in 33% of cases, delayed bone age in 89%
  - second-hand smoke exposure
- key features
  - AVN of proximal femoral epiphysis, abnormal growth of the physis, and eventual remodeling of regenerated bone

Most common in adolescent athletes, especially jumping/sprinting sports

Children diagnosed with coxa plana <6 yr of age have improved prognosis

Clinical Features
- child with antalgic or Trendelenburg gait ± pain
- intermittent knee, hip, groin, or thigh pain
- flexion contracture (stiff hip)
- decreased internal rotation and abduction of hip
- limb length discrepancy (late)

Investigations
- x-ray: AP pelvis, frog leg lateral
- initially, may be negative; if high index of suspicion, obtain bone scan or MRI
- eventually, collapse of femoral head will be seen (diagnostic)

Treatment
- goal is to keep femoral head contained in acetabulum and maintain ROM (contain and maintain)
- non-operative
  - physiotherapy: ROM exercises
  - restricted weight bearing
- operative
  - femoral or pelvic osteotomy (>8 yr of age or severe)
    - prognosis better in males, <6 yr, <50% of femoral head involved, abduction >30°
- 60% of involved hips do not require operative intervention
- natural history is early onset OA and decreased ROM

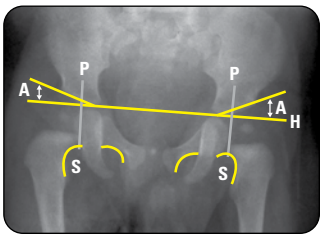

Figure 53. Pelvic x-ray and reference lines and angles for assessment of DDH
Triradiate Cartilage
y-shaped epiphyseal plate at junction of ilium, ischium, and pubis
Hilgenreiner's Line
Line running between triradiate cartilages
Perkin's Line
Line through lateral margin of acetabulum, perpendicular to Hilgenreiner's Line
Shenton's Line
Arced line along inferior border of femoral neck and superior margin of obturator foramen
Acetabular Index
Angle between Hilgenreiner's Line and line from triradiate cartilage to point on lateral margin of acetabulum

Osgood-Schlatter Disease

Definition
- inflammation of patellar ligament at insertion point on tibial tuberosity
- M>F; boys 12-15 yr; girls 8-12 yr

Mechanism
- repetitive tensile stress on insertion of patellar tendon over the tibial tuberosity causes minor avulsion at the site and subsequent inflammatory reaction (tibial tubercle apophysitis)

Clinical Features
- tender lump over tibial tuberosity
- pain on resisted leg extension
- anterior knee pain exacerbated by jumping or kneeling, relieved by rest

Investigations
- x-ray lateral knee: fragmentation of the tibial tubercle, ± ossicles in patellar tendon

Treatment
- benign, self-limited condition, does not resolve until growth halts
- non-operative (majority)
  - avoid aggravating activities such as basketball or cycling
  - NSAIDs, rest, flexibility, isometric strengthening exercises
  - casting if symptoms do not resolve with conservative management
- operative: ossicle excision in refractory cases (patient is skeletally mature with persistent symptoms)

Congenital Talipes Equinovarus (Club Foot)

Definition
- congenital foot deformity
- muscle contractures resulting in CAVE deformity
- bony deformity: talar neck medial and plantar deviated; varus calcaneus and rotated medially around talus; navicular and cuboid medially displaced

Etiology
- intrinsic causes (neurologic, muscular, or connective tissue diseases) vs. extrinsic (intrauterine growth restriction); may be idiopathic, neurogenic, or syndrome-associated
- fixed deformity
- 1-2 in 1000 newborns, 50% bilateral, occurrence M>F, severity F>M

Physical Exam
- examine for CAVE deformity
- examine hips for associated DDH
- examine knees for deformity
- examine back for dysraphism (unfused vertebral bodies)
- diagnosis is often from physical exam findings alone, radiographs not always required

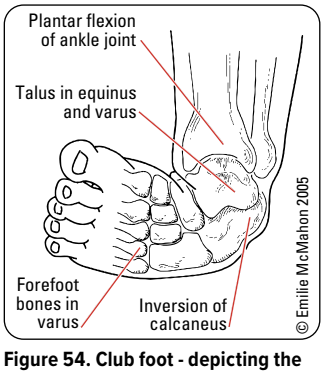

Figure 54. Club foot - depicting the gross and bony deformity

Treatment
- largely non-operative via Ponseti Technique (serial manipulation and casting)
  - correct deformities in CAVE order
    - change strapping/cast q1-2 wk
    - surgical release in refractory case (rare)
- delayed until age 3-4 mo
- 3 yr recurrence rate = 5-10%
- mild recurrence common; affected foot is permanently smaller/stiffer than normal foot with calf muscle atrophy

CAVE deformity
Midfoot **C**avus
Forefoot **A**dductus
Hindfoot **V**arus
Hindfoot **E**quinus

Scoliosis

Definition
- lateral curvature of spine with vertebral rotation
- age: 10-14 yr
- more frequent and more severe in females

Etiology
- idiopathic: most common (90%)
- congenital: vertebrae fail to form or segment
- neuromuscular: UMN or LMN lesion, myopathy
- postural: leg length discrepancy, muscle spasm
- other: osteochondrodystrophies, neoplastic, traumatic

Clinical Features
- cosmetic concern ± back pain
- primary curve where several vertebrae affected
- secondary compensatory curves above and below fixed primary curve to try to maintain normal position of head and pelvis
- asymmetric shoulder height when bent forward
- Adam's test: thoracic or lumbar prominence on affected side with forward bend at the waist
- prominent scapulae, creased flank, asymmetric pelvis
- associated posterior midline skin lesions in neuromuscular scoliosis
  - café-au-lait spots, dimples, neurofibromas
  - axillary freckling, hemangiomas, hair patches
- associated pes cavus or leg atrophy
- apparent leg length discrepancy

Investigations
- x-ray: 3-foot standing, AP, lateral
  - measure curvature: Cobb angle
  - may have associated kyphosis

Treatment
- based on Cobb angle
  - <25°: observe for changes with serial radiographs
  - >25° or progressive: bracing (many types, controversial) that halt/slow curve progression but do not reverse deformity
  - >45°, cosmetically unacceptable, or respiratory problems: surgical correction (spinal fusion)

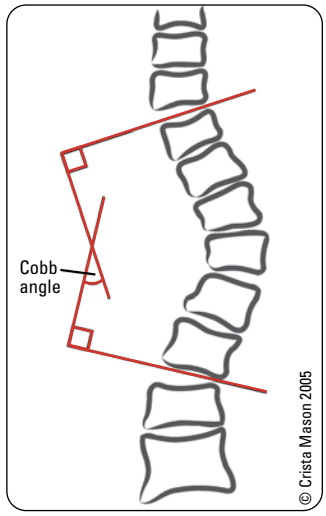

Figure 55. Cobb angle – used to monitor the progression of the scoliotic curve

Scoliosis screening is not recommended in Canada (Grieg A, et al. 2010; Health Canada, 1994)

In structural or fixed scoliosis, bending forwards makes the curve more obvious

Postural scoliosis can be corrected by correcting the underlying etiology

Bone Tumours

- primary bone tumours are rare after 3rd decade
- metastases to bone are relatively common after 3rd decade

Clinical Features
- malignant (primary or metastasis): local pain and swelling (weeks to months), worse on exertion and at night, ± soft tissue mass
- minor trauma can be the initiating event that calls attention to lesion

Red Flags
- Persistent skeletal pain
- Localized tenderness
- Spontaneous fracture
- Enlarging mass/soft tissue swelling

Table 25. Distinguishing Benign from Malignant Bone Lesions on X-Ray

Benign	Malignant
No periosteal reaction or benign appearing reaction (e.g. uniform smooth periosteal thickening as seen in a healing fracture)	Acute periosteal reaction • Codman's triangle • "Onion skin" • "Sunburst"
Sharp, well-demarcated borders, narrow zone of transition (between lesion and normal bone, suggesting slow-growing lesion)	Poorly defined borders, with a wide zone of transition, or infiltrative (suggesting fast-growing lesion)
Well-developed bone formation	Varied bone formation
Intraosseous and even calcification	Extraosseous and irregular calcification
No soft tissue mass	Soft tissue mass present
No cortical destruction or uniform cortical destruction in some low grade and locally aggressive benign lesions	Aggressive cortical destruction or tumour infiltration without cortical destruction

Adapted from: Buckholtz RW, Heckman JD. Rockwood and Green's Fractures in Adults. Volume 1. Philadelphia: Lippincott Williams & Wilkins, 2001. p558

X-ray Findings
- Lytic, lucent, sclerotic bone
- Involvement of cortex, medulla, soft tissue
- Radiolucent, radiopaque, or calcified matrix
- Periosteal reaction
- Permeative margins
- Pathological fracture
- Soft tissue swelling

Diagnosis
- malignancy is suggested by rapid growth, warmth, tenderness, aggressive features on imaging
- may be associated with constitutional symptoms such as fevers, night sweats, weight loss, or loss of appetite
- staging should include:
  - blood work (CBC, electrolytes, liver function assays, inflammatory markers, bone profile// extended electrolytes including calcium)
  - serum electrophoresis for older patients ± Bence Jones protein
  - full length radiographs of the affected bone
  - CT chest /abdo/pelvis
  - biopsy
    - should be referred to specialized centre prior to biopsy
  - ± CT and/or MRI of affected bone

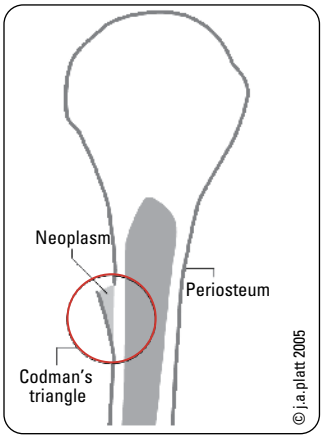

Figure 56. Codman's triangle
A radiographic finding in malignancy, where the partially ossified periosteum is lifted off the cortex by neoplastic tissue

Benign Active Bone Tumours

BONE-FORMING TUMOURS

Osteoid Osteoma
- benign bone tumour arising from osteoblasts; not known to metastasize
- peak incidence in 2nd and 3rd decades, M:F=2-3:1
- proximal femur>tibia diaphysis most common locations; spine (can cause painful scoliosis)
- radiographic findings: small, round radiolucent nidus (<1.5 cm) surrounded by dense sclerotic bone ("bull's-eye")
- symptoms: constant and progressive pain from prostaglandin secretion and COX1/2 expression
  - pain worse at night (diurnal prostaglandin production); characteristically relieved by NSAIDs
- treatment: NSAIDs are first-line; percutaneous radiofrequency ablation; surgical resection

FIBROUS LESIONS

Fibrous Cortical Defect (i.e. non-ossifying fibroma, fibrous bone lesion)
- developmental defect in which areas that normally ossify are filled with fibrous connective tissue
- most common benign bone tumour in children, typically asymptomatic and an incidental finding
- occur in as many as 35% of children, peak incidence between 2-25 yr old
- distal femur > distal tibia > proximal tibia most common locations
- radiographic findings: diagnostic, metaphyseal eccentric 'bubbly' lytic lesion near physis; thin, smooth/lobulated, well-defined sclerotic margin
  - multiple lesions can be present; large lesions may be associated with pathologic fractures
- treatment: most lesions resolve spontaneously; curettage and bone grafting for symptomatic lesions or to prevent pathologic fractures in larger lesions

Osteochondroma
- cartilage capped bony lesion arising on the external surface of a bone
- 2nd and 3rd decades, M>F
- most common benign bone tumour (~30%); true incidence unknown as many asymptomatic
- 2 types: sessile (broad based and increased risk of malignant degeneration) vs. pedunculated (narrow stalk)
- metaphysis of long bone near tendon attachment sites (distal femur, proximal tibia, or proximal humerus)
- radiographic findings: cartilage-capped bony spur on surface of bone ("mushroom" on x-ray)
- may be multiple (hereditary, autosomal dominant form) – higher risk of malignant change
- generally very slow growing and asymptomatic unless impinging on neurovascular structure ('painless mass')
  - growth usually ceases when skeletal maturity is reached
- malignant degeneration occurs in 1-2% (becomes painful or rapidly grows)
- treatment: observation; surgical excision if symptomatic or concern for malignant transformation

Enchondroma
- benign hyaline cartilage growth; abnormality of chondroblasts, develops in medullary cavity
  - single/multiple enlarged rarefied areas in tubular bones
  - lytic lesion with sharp margination and irregular central calcification (stippled/punctate/popcorn appearance)
- majority asymptomatic, presenting as incidental finding or pathological fracture
- 2nd and 3rd decades
- 60% occur in the small tubular bones of the hand and foot; others in femur (20% - Figure 57), humerus, ribs
- radiographic findings: well-defined, lucent, central medullary lesions that calcify over time
- malignant degeneration to chondrosarcoma occurs in 1-2% (rest/nocturnal pain in absence of pathologic fracture is an important clue
- treatment: observation with serial x-rays; surgical curettage if symptomatic or lesion grows

Figure 57. T1 MRI of femoral Enchondroma

CYSTIC LESIONS

Unicameral/Solitary Bone Cyst
- most common cystic lesion; serous fluid-filled lesion with fibrous lining
- children and young adults, peak incidence during first 2 decades
- proximal humerus and femur most common
- symptoms: asymptomatic, or localized pain; complete pathological fracture (50% of presentations) or incidental detection
- radiographic findings: lytic translucent area on metaphyseal side of growth plate, cortex thinned/expanded; well-defined lesion
- treatment: observation with serial radiography 4-6 mo; if needed, aspiration followed by steroid injection; curettage ± bone graft indicated if structural integrity of bone is compromised

Benign Aggressive Bone Tumours

Giant Cell Tumours/Aneurysmal Bone Cyst/Osteoblastoma
- affects patients of skeletal maturity, peak 3rd decade
- osteoblastoma: most commonly found in posterior elements of spine
- giant cell tumour: pulmonary metastases in 3%
- aneurysmal bone cysts: either solid with fibrous/granular tissue, or blood-filled
- radiographic findings
  - giant cell tumour: eccentric lytic lesions in epiphyses adjacent to subchondral bone; may break through cortex; T2 MRI enhances fluid within lesion (hyper-intense signal)
  - aneurysmal bone cyst: expansile, eccentric, and lytic lesion with bony septae ("bubbly appearance"); will have fluid-fluid levels on MRI
  - osteoblastoma: often nonspecific; calcified central nidus (>2 cm) with radiolucent halo and sclerosis
- symptoms: local tenderness and swelling, pain may be progressive (giant cell tumours), ± symptoms of nerve root compression (osteoblastoma)

Figure 58. X-ray of aneurysmal bone cyst
Note the aggressive destruction of bone

Treatment
- intralesional curettage + bone graft or cement
- wide local excision of expendable bones
- recurrence rates of up to 20%

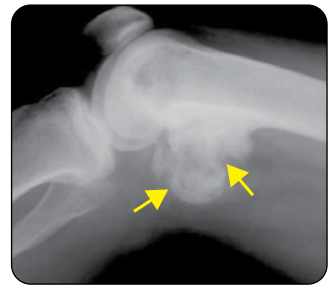

Figure 59. X-ray of osteosarcoma of distal femur

Malignant Bone Tumours

Table 26. Most Common Malignant Tumour Types for Age

Age	Tumour
<1	Neuroblastoma
1-10	Ewing's of tubular bones
10-30	Osteosarcoma, Ewing's of flat bones
30-40	Reticulum cell sarcoma, fibrosarcoma, periosteal osteosarcoma, malignant giant cell tumour, lymphoma
>40	Metastatic carcinoma, multiple myeloma, chondrosarcoma

Osteosarcoma

- malignant bone tumour
- 2nd most common primary malignancy in adults after myeloma
- majority occur in 2nd decade of life, second peak in elderly patients with history of Paget's disease
- predilection for sites of rapid growth: distal femur (45% - Figure 59, OR51), proximal tibia (20%), and proximal humerus (15%)
  - invasive, variable histology; frequent metastases without treatment (lung most common)
- painful symptoms: progressive pain, night pain, poorly defined swelling, decreased ROM
  - radiographic findings: characteristic blastic and destructive lesion ("sunburst" pattern), periosteal reaction (Codman's triangle), soft tissue mass with maintenance of bone cortices; destructive lesion in metaphysis may cross epiphyseal plate
  - bone scan – rule out skeletal metastases; CT chest – rule out pulmonary metastases
- treatment: neo-adjuvant chemotherapy + limb salvage resection/reconstruction (rarely amputation); post-surgical neo-adjuvant chemotherapy
- prognosis: 90% survival for low-grade; 70% survival for high-grade

Chondrosarcoma

- malignant chondrogenic tumour
- primary (2/3 cases)
  - previous normal bone, patient >40 yr; expands into cortex to cause pain, pathological fracture
- secondary (1/3 cases)
  - malignant degeneration of pre-existing cartilage tumour such as enchondroma or osteochondroma
  - age range 25-45 yr, better prognosis than primary chondrosarcoma
- symptoms: progressive pain, uncommonly palpable mass, pathologic fracture
- radiographic findings: in medullary cavity, irregular "popcorn" calcification
- treatment: no role for neo-adjuvant chemotherapy or radiation; treat with wide surgical resection + reconstruction; regular follow-up x-rays of resection site and chest
- prognosis: 90% ten-year survival for low-grade; 29-55% survival for high-grade

Ewing's Sarcoma

- malignant, small round cell sarcoma; metastases frequent without treatment
- most occur between ages 5-25 yr
- florid periosteal reaction in metaphysis of long bone with diaphyseal extension
- signs/symptoms: presents with pain, fever, erythema, and swelling; anemia, increased WBC, ESR, LDH (mimics an infection)
- radiographic findings: destructive lesion with moth-eaten appearance and periosteal lamellated pattern ("onion-skinning")
- treatment: resection + chemotherapy ± radiation
- prognosis: 70% survival; distant metastases significantly lower survival (<30%)

Multiple Myeloma

- proliferation of neoplastic plasma cells
- most common primary bone malignancy
- 90% occur in people >40 yr; M:F=2:1; twice as common in individuals of African descent
- signs/symptoms: localized bone pain (cardinal early symptom), compression/pathological fractures, renal failure, nephritis, high incidence of infections (e.g. pyelonephritis/pneumonia), systemic (weakness, weight loss, anorexia)
- labs: anemia, thrombocytopenia, increased ESR, hypercalcemia, increased Cr
- radiographic findings: multiple, "punched-out" well-demarcated lesions, no surrounding sclerosis, marked bone expansion
- diagnosis
  - serum/urine immunoelectrophoresis (monoclonal gammopathy)
  - CT-guided biopsy of lytic lesions at multiple bony sites
- treatment
  - multiagent chemotherapy ± stem cell transplantation ± bisphosphonates
  - surgery for impending fractures: debulking, internal fixation
- prognosis: 5 yr survival 52%, prognosis increases with decreasing age
- see Hematology, H51

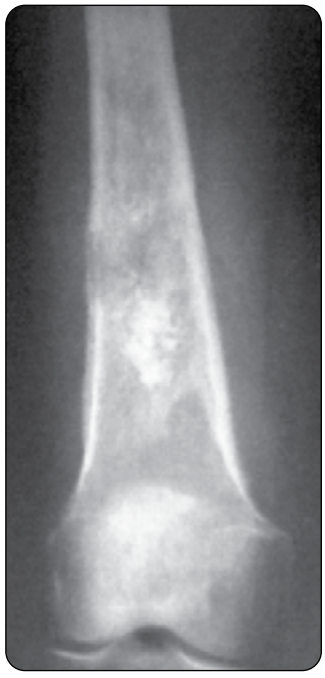

Figure 60. X-ray of femur Chondrosarcoma

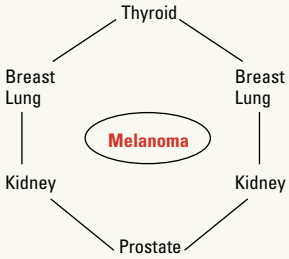
Signs of Hypercalcemia
"Bones, Stones, Moans, Groans, Psychiatric overtones"
CNS: headache, confusion, irritability, blurred vision
GI: N/V, abdominal pain, constipation, weight loss
MSK: fatigue, weakness, unsteady gait, bone and joint pain
GU: nocturia, polydipsia, polyuria, UTIs

Most Common Tumours Metastatic to Bone



BLT with a Kosher Pickle
Breast
Lung
Thyroid
Kidney
Prostate

Bone Metastases

- most common cause of bone lesions in adults; typically age >40
- majority arise from breast or prostate; some arise from lung, thyroid, and kidney
- usually osteolytic lesions; prostate occasionally osteoblastic
- may present with mechanical pain and/or night pain, pathological fracture, hypercalcemia
- bone scan for MSK involvement; MRI if suspected spinal involvement
- treatment: pain control, bisphosphonates, surgical stabilization of impending fractures if Mirel's Critera >8

Table 27. Mirel's Criteria for Impending Fracture Risk and Prophylactic Internal Fixation

Variable	Number Assigned		
	1	2	3
Site	Upper arm	Lower extremity	Peritrochanteric
Pain	Mild	Moderate	Severe
Lesion	Blastic	Mixed	Lytic
Size	<1/3 bone diameter	1/3-2/3 diameter	>2/3 diameter

Common Medications

Table 28. Common Medications

Drug Name	Dosing Schedule	Indications	Comments
cefazolin (Ancef®)	1-2 g IV q8 h	Preoperative antibiotic prophylaxis	First generation cephalosporin; can be used with penicillin allergy (<10% cross-reactivity; significantly higher rates of SSI/PJI with alternative ABx)
LMWH dalteparin (Fragmin®) enoxaparin (Lovenox®)	5000 IU SC once daily 30-40 mg SC once daily to BID 2.5 mg SC once daily	DVT prophylaxis	Fixed dose, no monitoring, improved bioavailability, increased bleeding rates
oral anticoagulants dabigatran (Pradaxa®) rivaroxaban (Xarelto®) apixaban (Eliquis®)	110 mg PO x1 then 220 mg PO once daily 10 mg PO once daily 2.5 mg PO BID	DVT prophylaxis	Predictable, no monitoring, oral administration Reversal agents: idarucizumab (dabigatran) andexanet alfa (rivaroxaban, apixaban)
tranexamic acid (TXA)	10-20 mg/kg IV Topical application to wound	Reduce perioperative blood loss and transfusion	No evidence for increase in thromboembolic events
acetaminophen (Tylenol®)	1000 mg PO q6 h or q8 h	Analgesia for pain control	Max dose up to 4000 mg every 24 h Higher doses can be hepatotoxic in susceptible individuals
ibuprofen (Advil®, Motrin®)	200-800 mg PO q6-8 h (max 3200 mg/d)	Analgesia for inflammatory pain (arthritis)	NSAID, may cause gastric erosion and bleeding; avoid if concurrent advanced renal disease
triamcinolone (Aristocort®) – an injectable steroid	0.5-1 mL of 25 mg/mL	Suspension (injected into inflamed joint or bursa); amount varies by joint size	Potent anti-inflammatory effect; increased pain for 24 h, rarely causes fat necrosis and skin depigmentation
naproxen (Aleve®, Naprosyn®)	250-500 mg BID	Analgesia for pain due to inflammation, arthritis, soft tissue injury	NSAID, may cause gastric erosion and bleeding; avoid if concurrent advanced renal disease
celecoxib (Celebrex®)	200 mg PO BID	Component of multimodal pain control and prophylaxis of HO after THA	NSAID (COX-2 inhibitor), cardiotoxic
indomethacin (Indocid®)	25 mg PO TID	Prophylaxis of HO after THA	Use with misoprostol

Landmark Orthopaedic Trials

Trial Name	Reference	Clinical Trial Details
HEALTH	NEJM 2019; 381:2199-2208	**Title**: Total Hip Arthroplasty or Hemiarthroplasty for Hip Fracture **Purpose**: Despite being amongst the top 10 causes of disability in adults, there is still ambiguity in the treatment of displaced femoral neck fractures. **Methods**: 1495 patients who were 50+ years old and had a displaced femoral neck fracture were randomly assigned to have a total hip arthroplasty or hemiarthroplasty. **Results**: A secondary hip procedure within 24 months of follow-up occurred in 7.9% of the total hip arthroplasty and 8.3% of the hemiarthroplasty group. Hip instability occurred in 4.7% of the total hip arthroplasty, and 2.4% of the hemiarthroplasty group. Function was modestly better in total hip arthroplasty over hemiarthroplasty. **Conclusions**: The incidence of secondary procedures, and function over 24 months between the total hip arthroplasty and hemiarthroplasty group did not have a significant difference.
PROFHER	JAMA 2015 Mar 10;313(10):1037-47	**Title**: Surgical vs Nonsurgical Treatment of Adults with Displaced Fractures of the Proximal Humerus: the PROFHER Randomized Clinical Trial **Purpose**: To evaluate the efficacy of surgical management in adults with displaced fractures of the proximal humerus involving the surgical neck. **Methods**: A randomized clinical trial where 260 patients, who presented to 32 UK hospitals after sustaining a displaced fracture of the proximal humerus involving the surgical neck were randomized into surgical and nonsurgical treatment groups, then followed for 2 years. **Results**: No significant mean treatment group differences in Oxford Shoulder Score averaged over 2 years (39.07 points for the surgical group vs 38.32 points for the nonsurgical group; difference of 0.75 points [95% CI, -1.33 to 2.84 points]; P = .48). **Conclusions**: No significant differences between surgical treatment vs non-surgical treatment. These results do not support the use of surgery for patients with displaced proximal humerus fractures involving the surgical neck.
FLOW	N Engl J Med 2015; 373:2629-2641	**Title**: A Trial of Wound Irrigation in the Initial Management of Open Fracture Wounds **Purpose**: To investigate the effects of castile soap versus normal saline irrigation delivered by means of high, low, or very low irrigation pressures. **Methods**: 2551 patients from 41 clinical centers, who had an open fracture of an extremity undergoing irrigation were randomly assigned to one of three irrigation pressures (high, low, and very low) and one of two irrigation solutions (castile soap versus normal saline). The primary outcome in this study was reoperation within 12 months after the initial surgery. **Results**: Hazard ratio showed no significant difference between the rates of reoperation within 12 months between the different irrigation pressures. Reoperation occurred in 14.8% in the soap group and in 11.6% in the saline group (hazard ratio, 1.32, 95% CI, 1.06 to 1.66; P=0.01). **Conclusions**: Rates of reoperation were similar regardless of irrigation pressure. The reoperation rate was higher in the soap group than in the saline group. These findings indicate low pressure saline irrigation is an acceptable form of wound irrigation.

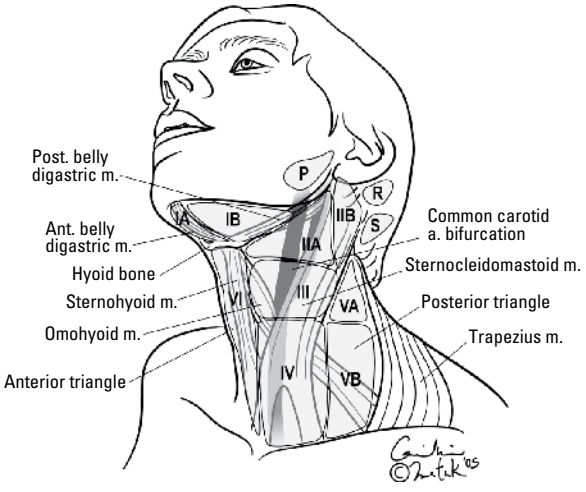

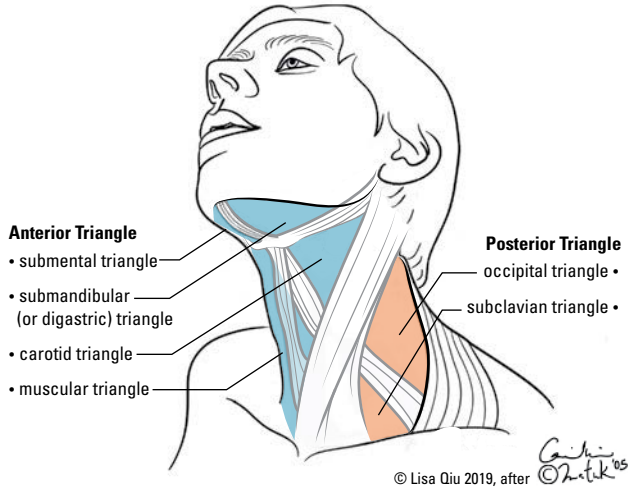

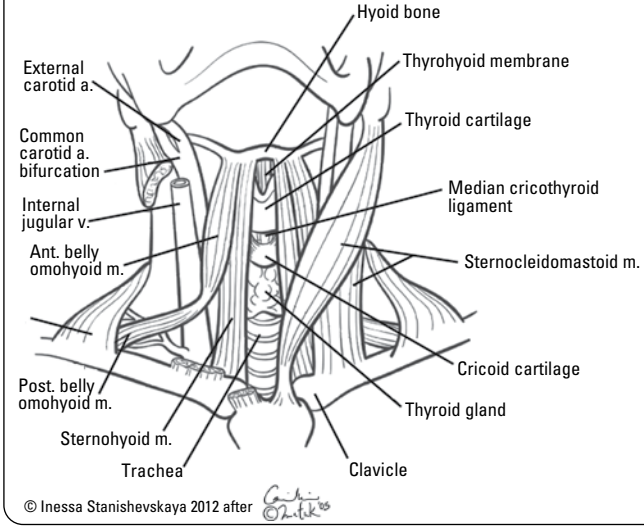

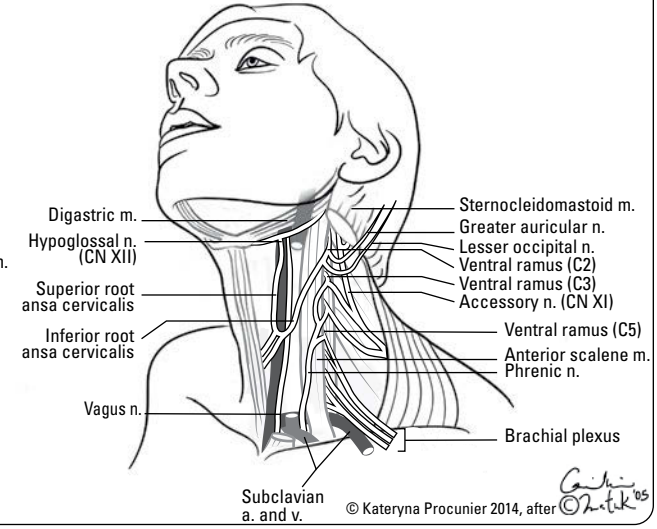

Figure 9. Anatomy of the neck

Anatomical Triangles of the Neck

Anterior triangle
- bound by anterior border of SCM, midline of neck, and lower border of mandible
- divided into:
  - **submental triangle**: bound by both anterior bellies of the digastric muscles from the mentum to the hyoid bone
  - **digastric triangle**: bounded by anterior and posterior bellies of the digastric muscles and inferior border of mandible
  - **carotid triangle**: bounded by SCM, anterior belly of the omohyoid muscles, and posterior belly of digastric muscles
    - contains: tail of parotid, submandibular gland, hypoglossal nerve, carotid bifurcation, and lymph nodes

Posterior triangle
- bound by posterior border of the SCM, anterior border of trapezius, and middle third of clavicle
- divided into:
  - **occipital triangle**: superior to posterior belly of the omohyoid
  - **subclavian triangle**: inferior to posterior belly of omohyoid
- contains: spinal accessory nerve and lymph nodes

Table 1. Lymphatic Drainage of Nodal Groups and Anatomical Triangles of the Neck

Nodal Group/Level	Location	Drainage
1. Suboccipital (S)	Base of skull, posterior	Posterior scalp
2. Retroauricular (R)	Superficial to mastoid process	Scalp, temporal region, external auditory meatus, posterior pinna
3. Parotid-preauricular (P)	Anterior to ear	External auditory meatus, anterior pinna, soft tissue of frontal and temporal regions, root of nose, eyelids, palpebral conjunctiva
4. Submental (Level IA)	Anterior bellies (midline) of digastric muscles, tip of mandible, and hyoid bone	Floor of mouth, anterior tongue, anterior mandibular alveolar ridge, lower lip
5. Submandibular (Level IB)	Anterior belly of digastric muscles, stylohyoid muscle, body of mandible	Oral cavity, anterior nasal cavity, soft tissues of the mid-face, submandibular gland
6. Upper jugular (Levels IIA and IIB)	Skull base to inferior border of hyoid bone along SCM muscle	Oral cavity, nasal cavity, naso/oro/hypopharynx, larynx, parotid glands
7. Middle jugular (Level III)	Inferior border of hyoid bone to inferior border of cricoid cartilage along SCM muscle	Oral cavity, naso/oro/hypopharynx, larynx
8. Lower jugular* (Level IV)	Inferior border of cricoid cartilage to clavicle along SCM muscle	Hypopharynx, thyroid, cervical esophagus, larynx
9. Posterior triangle (Levels VA and VB)**	Posterior border of SCM, anterior border of trapezius, from skull base to clavicle	Nasopharynx and oropharynx, cutaneous structures of the posterior scalp and neck
10. Anterior compartment* (Level VI)**	Hyoid bone (midline) to suprasternal notch between the common carotid arteries	Thyroid gland, glottic, and subglottic larynx, apex of piriform sinus, cervical esophagus

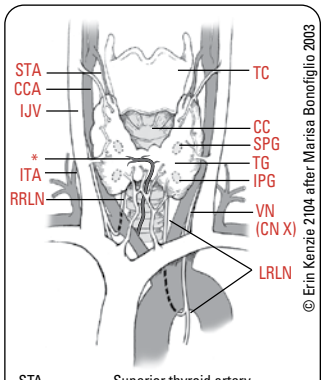
*Virchow's node: left lower jugular (level IV) supraclavicular node
**Includes some supraclavicular nodes
***Includes pretracheal, precricoid, paratracheal, and perithyroidal nodes

Paired Parasympathetic Ganglia of the Head and Neck
- **Ciliary (supplied by CN III):** pupillary constriction
- **Pterygopalatine (supplied by CN VII):** lacrimal gland, nasal mucosa
- **Submandibular (supplied by CN VII):** submandibular, sublingual glands
- **Otic (supplied by CN IX):** parotid gland

Functions of the Facial Nerve
"Ears, Tears, Face, Taste"
Ears: stapedius muscle, sensory around concha of auricle, EAC, and TM
Tears: lacrimation (lacrimal gland) and salivation (submandibular and sublingual glands)
Face: muscles of facial expression
Taste: sensory anterior ⅔ of tongue (via chorda tympani)

Lymphadenopathy
- **Left-sided** enlargement of a supraclavicular node (Virchow's node) may indicate an abdominal malignancy or malignancy below the clavicle
- **Right-sided** enlargement may indicate malignancy of the mediastinum, lungs, or esophagus
- **Occipital and/or posterior auricular node** enlargement may indicate rubella

4 Strap Muscles of the Neck
- Thyrohyoid
- Omohyoid
- Sternohyoid
- Sternothyroid



STA – Superior thyroid artery
CCA – Common carotid artery
IJV – Internal jugular vein
ITA – Inferior thyroid artery
RRLN – Right recurrent laryngeal nerve
TC – Thyroid cartilage
CC – Cricoid cartilage
SPG – Superior parathyroid gland
TG – Thyroid gland
IPG – Inferior parathyroid gland
VN (CN X) – Vagus nerve (CN X)
LRLN – Left recurrent laryngeal nerve

*Thyroidea ima artery: present in 3% of population, arises from aortic arch or innominate artery

Figure 10. Anatomy of the thyroid gland

Differential Diagnoses of Common Presentation

Dizziness

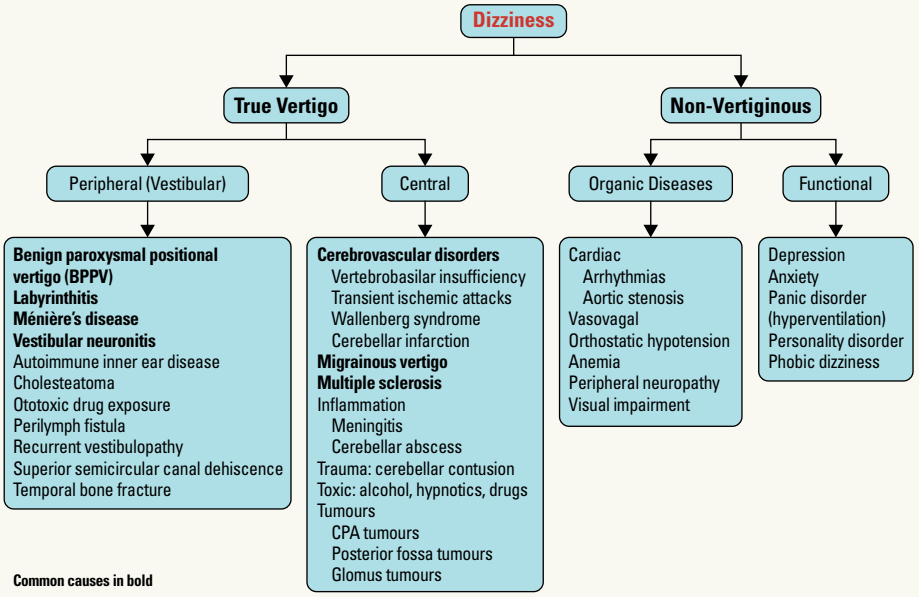


Figure 11. Differential diagnosis of dizziness

True nystagmus and vertigo caused by a peripheral lesion usually do not last longer than a few weeks, due to compensation from the cerebellum (unless there is a history of cerebellar ischemia/stroke). Central lesions do not compensate, therefore nystagmus and vertigo will persist

Findings Suggestive of Central Vertigo
Acute onset and continuous
Normal head impulse test
Multidirectional nystagmus
Skew deviation present

5 "D"s of Vertebrobasilar Insufficiency
Drop attacks
Diplopia
Dysarthria
Dizziness
Dysphagia

Otalgia

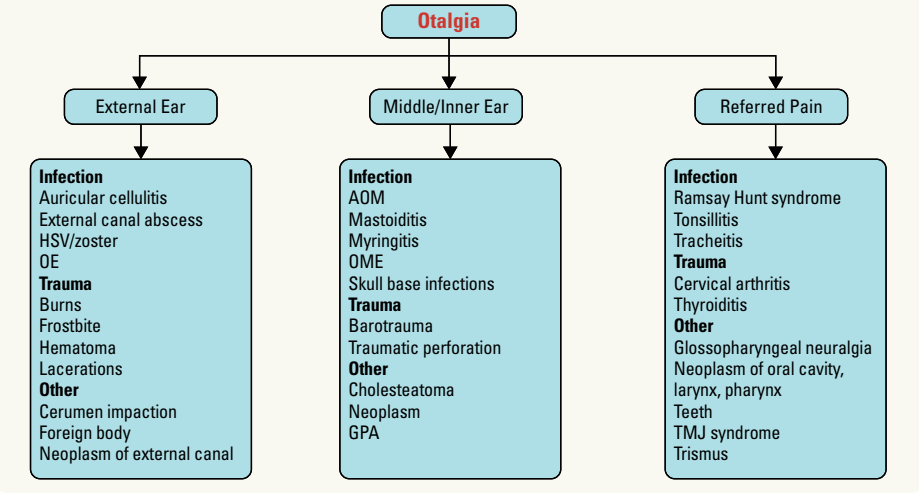

Figure 12. Differential diagnosis of otalgia

Otalgia – Referred Pain
Sensory innervation to the ear is supplied by CN V, VII, IX and X resulting in many sources of referred pain that can cause otalgia

The 10 T's of Referred Pain which Cause Otalgia
Teeth: Impacted wisdom teeth, caries, infant teething
TMD: Temporomandibular Joint Disease
Tubal Area: Eustachian tube dysfunction, nasopharynx (area behind the nose (rule out tumour)
Tonsils: Infections, tumours
Throat: Infections, tumors of pharynx, larynx (voice box)
Tongue: inflammation, tumour
Trachea: (windpipe), Larynx (voice box)
Thyroid Gland: infections, tumours
Tempora Arteritis: inflammation of the artery above the ear
Trauma

Hearing Loss

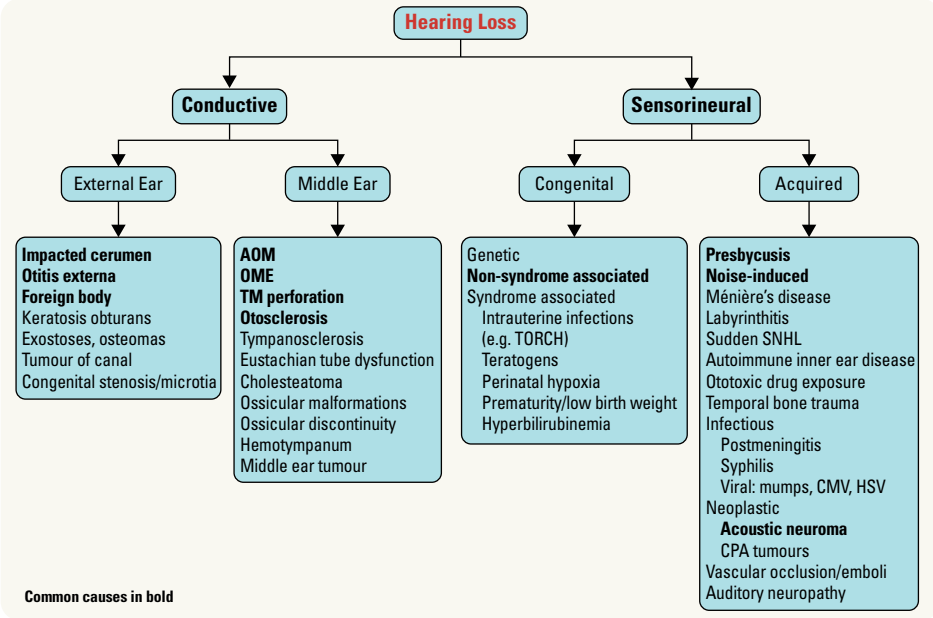

Figure 13. Differential diagnosis of hearing loss

Tinnitus

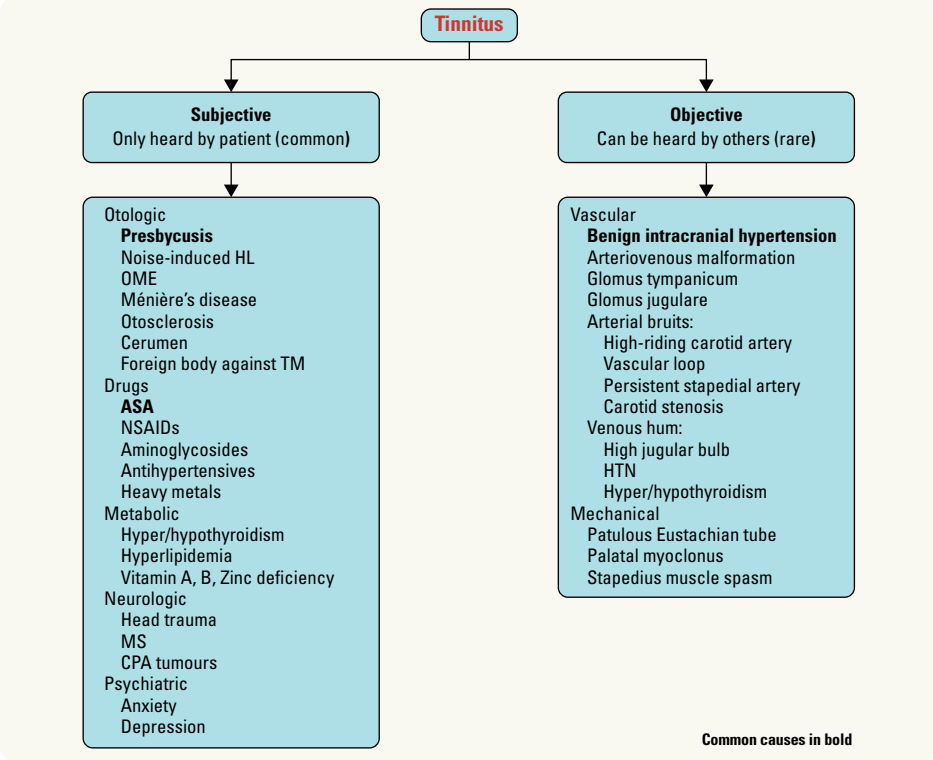

Figure 14. Differential diagnosis of tinnitus

Tinnitus is most commonly associated with SNHL

Glomus Tympanicum/Jugulare Tumour Signs and Symptoms

- Pulsatile tinnitus
- HL
- Blue mass behind TM
- Brown's sign (blanching of the TM with pneumatic otoscopy)

Nasal Obstruction

Table 2. Differential Diagnosis of Nasal Obstruction

	Acquired	Congenital
Nasal Cavity	Rhinitis	Pyriform aperture stenosis
	Acute/chronic	Choanal atresia
	Vasomotor	Dermoid cyst
	Allergic	Encephalocele
	Rhinosinusitis	Glioma
	Foreign bodies	
	Enlarged turbinates	
	Tumour	
	Benign: polyps, inverting papilloma (can become malignant)	
	Malignant	
	SCC	
	Esthesioneuroblastoma (olfactory neuroblastoma)	
	Adenocarcinoma	
Nasal Septum	Septal deviation	Septal deviation
	Septal dislocation	Septal dislocation
	Septal hematoma/abscess	Septal hematoma/abscess
Nasopharynx	Adenoid hypertrophy	
	Tumour	
	Benign: juvenile nasopharyngeal angiofibroma (JNA), polyps	
	Malignant: nasopharyngeal carcinoma	
Systemic		
GPA, diabetes, vasculitis		

Hoarseness

Lung malignancy is the most common cause of extralaryngeal vocal cord paralysis

Table 3. Differential Diagnosis of Hoarseness

Infectious	Acute/chronic laryngitis Laryngotracheobronchitis (croup)	
Inflammatory	GERD Vocal cord polyps/nodules Lifestyle: smoking, chronic alcohol use	
Traumatic	External laryngeal trauma Endoscopy and endotracheal tube (e.g. intubation granuloma)	
Neoplastic	Benign tumour Papillomas (HPV infection) Minor salivary gland tumours Other	Malignant tumours (e.g. thyroid) SCC Other
Cysts	Retention cysts	
Systemic	Endocrine Hypothyroidism Virilization	Connective tissue disease RA SLE
Neurologic (vocal cord paralysis due to superior ± recurrent laryngeal nerve injury)	Central lesions CVA Head injury MS Skull base tumours Arnold-Chiari malformation Peripheral lesions Unilateral Lung malignancy	Iatrogenic injury: thyroid, parathyroid surgery, carotid endarterectomy, patent ductus arteriosus (PDA) ligation Bilateral Iatrogenic injury: bilateral thyroid surgery, forceps delivery Neuromuscular Myasthenia gravis
Functional	Psychogenic aphonia (hysterical aphonia)	
Congenital	Laryngomalacia Laryngeal web Laryngeal atresia	

Neck Mass

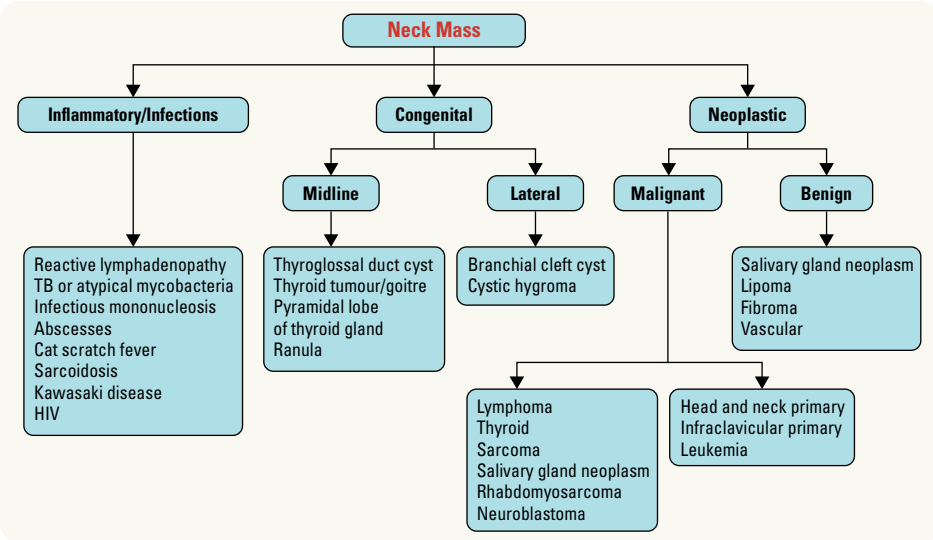

Figure 15. Differential diagnosis of a neck mass

Hearing

Normal Hearing Physiology

- conductive pathway (EAC to cochlea): AC of sound down the EAC ➔ vibration of TM ➔ sequential vibration of middle ear ossicles (malleus, incus, stapes) ➔ transmission of amplified vibrations from stapes footplate to the oval window of the cochlea ➔ vibrations transmitted via cochlear fluid create movement along the basilar membrane within the cochlea
- neural pathway (nerve to brain): basilar membrane vibration stimulates overlying hair cells in the organ of Corti ➔ stimulation of bipolar neurons in the spiral ganglion of the cochlear division of CN VIII propagates the signal through ➔ cochlear nucleus ➔ superior olivary nucleus ➔ lateral lemniscus ➔ inferior colliculus ➔ Sylvian fissure of temporal lobe

Order of the Neural Pathway (with Corresponding Waves on ABR)

E COLI
Eighth cranial nerve (I – II)
Cochlear nucleus (III)
Superior **O**livary nucleus
Lateral lemniscus (IV – V)
Inferior colliculus

Types of Hearing Loss

1. Conductive Hearing Loss

- conduction of sound to the cochlea is impaired
- can be caused by external and middle ear disease

2. Sensorineural Hearing Loss

- defect in the conversion of sound into neural signals or in the transmission of those signals to the cortex
- can be caused by disease of the inner ear (cochlea), acoustic nerve (CN VIII), brainstem, or cortex

3. Mixed Hearing Loss

- combination of CHL and SNHL

Auditory Acuity

- whispered-voice test: mask one ear and whisper into the other
- tuning fork tests (see Table 4, OT10; audiogram is of greater utility)
  - Rinne test
    - 512 Hz tuning fork is struck and held firmly on mastoid process to test BC; the tuning fork is then placed beside the pinna to test AC
    - if AC > BC ➔ positive Rinne (normal)
  - Weber test
    - 512 Hz tuning fork is held on vertex of head and patient states whether it is heard centrally (Weber negative) or is lateralized to one side (Weber right, Weber left)
    - can place vibrating fork on patient's chin while they clench their teeth, or directly on teeth to elicit more reliable response
    - will only lateralize if difference in HL between ears is >6 dB

Weber test lateralization = ipsilateral CHL or contralateral SNHL
The Weber test is more sensitive in detecting CHL than the Rinne test

Table 4. The Interpretation of Tuning Fork Tests

Examples	Weber	Rinne
Normal or bilateral SNHL	Central	AC>BC (+) bilaterally
Right-sided CHL, normal left ear	Lateralizes right	BC>AC (–) right
Right-sided SNHL, normal left ear	Lateralizes left	AC>BC (+) bilaterally
Right-sided severe SNHL or dead right ear, normal left ear	Lateralizes left	BC>AC (–) right*

*A vibrating tuning fork on the mastoid stimulates the cochlea bilaterally, therefore, in this case, the left cochlea is stimulated by the Rinne test on the right (e.g. a false negative test). These tests are not valid if the ear canals are obstructed with cerumen (e.g. will create conductive loss)

Frequency of Tuning Fork (Hz)	Minimum Hearing Loss for Rinne to Reverse (BC>AC, NEGATIVE Rinne) (dB)
256	15
512	30
1024	45

Pure Tone Audiometry

- a threshold is the lowest intensity level at which a patient can hear the tone 50% of the time
- thresholds are obtained for each ear at frequencies of 250, 500, 1000, 2000, 4000, and 8000 Hz
- air conduction thresholds are obtained with headphones and measure outer, middle, inner ear, and auditory nerve function
- bone conduction thresholds are obtained with bone conduction oscillators, which bypass the outer and middle ear

Range of Frequencies Audible to Human Ear
- 20 to 20000 Hz
- Most sensitive frequencies: 1000 to 4000 Hz
- Range of human speech: 500 to 2000 Hz

Degree of Hearing Loss

- determined on basis of the pure tone average (PTA) at 500, 1000, and 2000 Hz

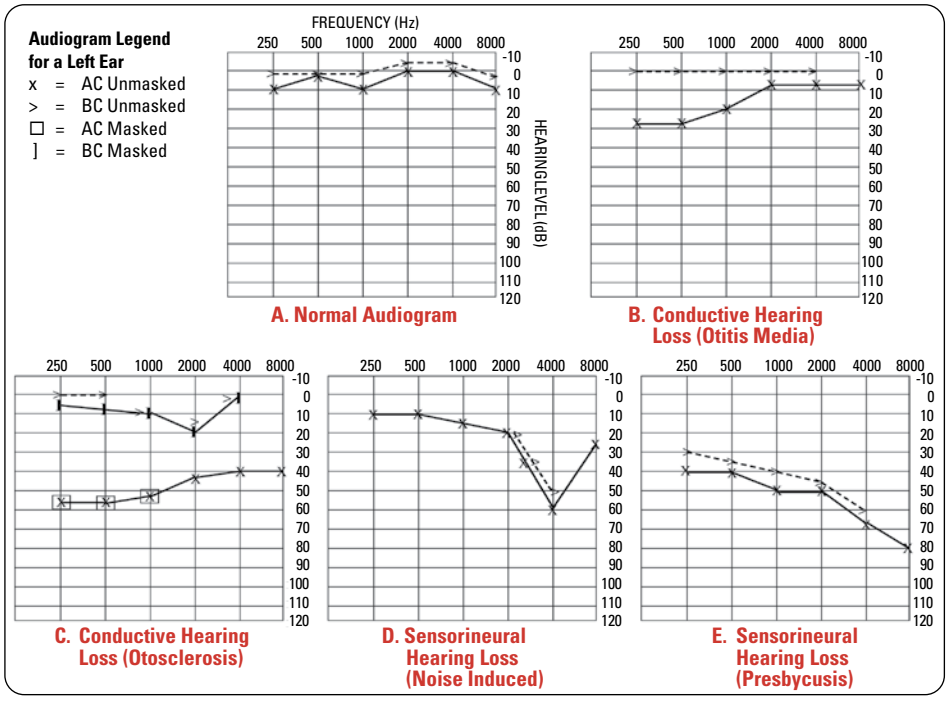

Figure 16. Types of hearing loss and associated audiograms of a left ear

HL occurs most often at higher frequencies. Noise-induced (occupational) HL is classically seen at 4000 Hz (Boilermaker's notch). HL associated with otosclerosis is seen at 2000 Hz (Carhart's notch)

PURE TONE PATTERNS

1. Conductive Hearing Loss (see **Figures 16B** and **16C**)
- BC in normal range
- AC outside of normal range
- gap between AC and BC thresholds >10 dB (an air-bone gap)

2. Sensorineural Hearing Loss (see **Figures 16D** and **16E**)
- both air and bone conduction thresholds below normal
- gap between AC and BC <10 dB (no air-bone gap)

3. Mixed Hearing Loss
- both air and bone conduction thresholds below normal
- gap between AC and BC thresholds >10 dB (an air-bone gap)

Speech Audiometry

Speech Reception Threshold
- lowest hearing level at which patient is able to repeat 50% of two syllable words which have equal emphasis on each syllable (spondee words)
- speech reception threshold (SRT) and best pure tone threshold in the 500 to 2000 Hz range (frequency range of human speech) usually agree within 5 dB; if not, suspect a retrocochlear lesion or functional HL
- used to assess the reliability of the pure tone audiometry

Speech Discrimination Test
- percentage of words the patient correctly repeats from a list of 50 monosyllabic words
- tested at 40 dB above the patient's SRT, therefore degree of HL is taken into account
- patients with normal hearing or CHL score >90%
- rollover effect: a decrease in discrimination as sound intensity increases; typical of a retrocochlear lesion (e.g. acoustic neuroma)
- investigate further if scores differ more than 20% between ears, as asymmetry may indicate a retrocochlear lesion
- best predictor of hearing aid response: a poor discrimination score indicates significant neural degeneration and hearing aids may not be the best option for the patient

Impedance Audiometry

Tympanogram
- the Eustachian tube equalizes the pressure between the external and middle ear
- tympanograms graph the compliance of the middle ear system against a pressure gradient ranging from –400 to +200 mmH_2O
- tympanogram peak occurs at the point of maximum compliance: where the pressure in the external canal is equivalent to the pressure in the middle ear
- normal range: –100 to +50 mmH_2O

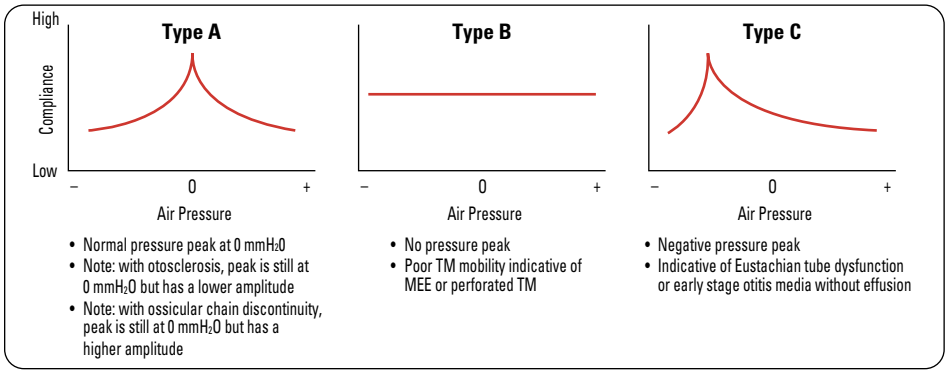

Figure 17. Tympanograms

Static Compliance
- volume measurement reflecting overall stiffness of the middle ear system
- normal range: 0.3-1.6 cc
- negative middle ear pressure and abnormal compliance indicate middle ear pathology
- in a type B curve, ear canal volumes of >2 cc in children and >2.5 cc in adults indicate TM perforation or presence of a patent ventilation tube

Acoustic Stapedial Reflexes
- stapedius muscle contracts in response to loud sound
- acoustic reflex threshold = 70-100 dB greater than hearing threshold; if hearing threshold >85 dB, reflex likely absent
  - stimulating either ear causes bilateral and symmetrical reflexes
  - for reflex to be present, CN VII must be intact with no CHL in monitored ear
  - if reflex is absent without CHL or severe SNHL, suspect CN VII lesion
- acoustic reflex decay test = ability of stapedius muscle to sustain contraction for 10 s at 10 dB
  - normally, little reflex decay occurs at 500 and 1000 Hz
- with cochlear HL, acoustic reflex thresholds are 25-60 dB
- with retrocochlear HL (acoustic neuroma), absent acoustic reflexes or marked reflex decay (>50%) within 5 s

Auditory Brainstem Response

- measures neuroelectric potentials (waves) in response to a stimulus in five different anatomic sites (see *Order of the Neural Pathway* sidebar, OT9; this test can be used to determine the site of lesion)
- delay in brainstem response suggests cochlear or retrocochlear abnormalities
- does not require volition or co-operation of patient (therefore, value retained in children and malingerers)

Otoacoustic Emissions

- objective test of hearing where a series of clicks is presented to the ear and the cochlea generates an echo which can be measured
- signals come from outer hair cells which are a proxy for the inner hair cells which facilitate hearing
- often used in newborn screening
- can be used to uncover normal hearing in malingering patients
- absence of emissions can be due to HL, fluid in the middle ear, or narrow EACs

Prelingual deafness: deafness occurring before speech and language are acquired
Postlingual deafness: deafness occurring after speech and language are acquired

Aural Rehabilitation

- dependent on degree of HL, communicative requirements, motivation, expectations, and physical and mental abilities
- negative prognostic factors
  - poor speech discrimination
  - narrow dynamic range (recruitment)
  - unrealistic expectations
- types of hearing aids
  - BTE: behind-the-ear (with occlusive mould or open fit which allows natural sound to pass – for less severe hearing loss)
  - ITE: in-the-ear, placed in concha
  - ITC: in-the-canal, placed entirely in ear canal
  - CIC: contained-in-canal, placed deeply in ear canal
  - BAHA: bone-anchored hearing aid: attached to skull (bone conduction)
  - CROS: contralateral routing of signals
- assistive listening devices
  - direct/indirect audio output
  - infrared, FM radio, or induction loop systems
  - telephone, television, or alerting devices
- cochlear implants
  - electrode is inserted into the cochlea to allow direct stimulation of the auditory nerve
  - for profound bilateral SNHL refractory to conventional hearing aids
  - established indication: postlingually deafened adults, pre and postlingually deaf children

Prelingually deaf infants are the best candidates for aural rehabilitation because they have maximal benefit from ongoing developmental plasticity

Bone-Anchored Hearing Aids (BAHA)
BAHAs function based on bone conduction and are indicated primarily for patients with CHL, unilateral HL, and mixed HL who cannot wear conventional hearing aids. BAHAs consist of an osseointegrated titanium implant, an external abutment, and a sound processor. The sound processor transmits vibrations through the external abutment to the titanium implant and then directly to the cochlea

Vertigo

Evaluation of the Dizzy Patient

- vertigo: illusion of rotational, linear, or tilting movement of self or environment
  - produced by peripheral (inner ear) or central (brainstem-cerebellum) stimulation
  - important to distinguish vertigo from other potential causes of "dizziness" (see Figure 11, OT6)

Table 5. Peripheral vs. Central Vertigo

Symptoms	Peripheral	Central
Imbalance	Moderate-severe	Mild-moderate
Nausea and Vomiting	Severe	Variable
Auditory Symptoms	Common	Rare
Neurologic Symptoms	Rare	Common
Compensation	Rapid	Slow
Nystagmus	Unidirectional Horizontal or rotatory	Bidirectional Horizontal or vertical

Table 6. Differential Diagnosis of Vertigo Based on History

Condition	Duration	Hearing Loss	Tinnitus	Aural Fullness	Other Features
Benign Paroxysmal Positional Vertigo (BPPV)	Seconds	–	–	–	
Ménière's Disease	Minutes to hours	Uni/bilateral, fluctuating	+	Pressure/warmth	
Labyrinthitis/ Vestibular Neuronitis	Hours to days	Unilateral	± Whistling	–	May have recent AOM
Acoustic Neuroma	Chronic	Progressive	+	–	Ataxia CN VII palsy

Table 7. Differential Diagnosis of Vertigo Based on Time Course

Time Course	Condition
Recurrent, lasting	BPPV
Single episode, lasting minutes to hours	Migraine, transient ischemia of the labyrinth or brainstem
Recurrent to hours	Ménière's
Prolonged	Vestibular neuritis, MS, brainstem/cerebellar infarct
Chronic	Acoustic neuroma

Benign Paroxysmal Positional Vertigo

Definition
- acute attacks of transient rotatory vertigo lasting seconds to minutes, initiated by certain head positions, accompanied by torsional (i.e. rotatory) nystagmus (geotropic = fast phase towards the floor)
- most common form of positional vertigo (50% of patients with peripheral vestibular dysfunction have BPPV)

Etiology
- due to canalithiasis (migration of free floating otoliths within the endolymph of the semicircular canal) or cupulolithiasis (otolith attached to the cupula of the semicircular canal)
  - can affect each of the 3 semicircular canals, although the posterior canal is affected in >90% of cases
  - caused by: head injury, viral infection (URTI), degenerative disease, idiopathic
  - results in slightly different signals being received by the brain from the two balance organs, resulting in sensation of movement

Diagnosis
- history (time course, provoking factors, associative symptoms)
- positive Dix-Hallpike maneuver (sensitivity 82%, specificity 71%)

Dix-Hallpike Positional Testing (see website for video and illustrations)
- the patient is rapidly moved from a sitting position to a supine position with the head hanging over the end of the table, turned to one side at 45°, and neck extended 20° holding the position for 20 s
- onset of vertigo and rotatory nystagmus indicate a positive test for the dependent side
- other diagnostic testing is not indicated in posterior canal BPPV

Treatment
- reassure patient that process resolves spontaneously
- particle repositioning maneuvers
  - Epley maneuver (performed by physician or by patient with the help of devices such as the DizzyFIX™)
  - Brandt-Daroff exercises (performed by patient)
- anti-emetics for N/V
- posterior semicircular canal occlusion or singular neurectomy for refractory cases
- drugs to suppress the vestibular system delay eventual recovery and are therefore not used

BPPV is the most common cause of episodic vertigo; patients are often symptomatic when rolling over in bed or moving their head to a position of extreme posterior extension (such as looking up at a tall building or getting their hair washed at the hairdresser)

Signs of BPPV Seen with Dix-Hallpike Maneuver
- Latency of ~20 s
- Crescendo/decrescendo vertigo lasting 20 s
- Geotropic rotatory nystagmus (nystagmus MUST be present for a positive test)
- Reversal of nystagmus upon sitting up
- Fatigability with repeated stimulation

Ménière's Disease (Endolymphatic Hydrops)

Definition
- episodic attacks of tinnitus, HL, aural fullness, and vertigo lasting min to h

Proposed Etiology
- inadequate absorption of endolymph leads to endolymphatic hydrops (over accumulation) that distorts the membranous labyrinth

Diagnostic Criteria for Ménière's Disease

Definite Ménière's Disease
- Two or more spontaneous episodes of vertigo lasting from 20 min to 12 h
- Audiometric confirmation of SNHL (low to mid frequency)
- Fluctuating tinnitus and/or aural fullness

Probable Ménière's Disease
- Two or more spontaneous episodes of vertigo or dizziness lasting from 20 min to 24 h
- Fluctuating tinnitus and/or aural fullness

Epidemiology
- peak incidence 40-60 yr
- bilateral in 35% of cases

Clinical Features
- episodic vertigo, fluctuating low frequency SNHL, tinnitus, and aural fullness, ± drop attacks (Tumarkin crisis), ± N/V
- vertigo disappears with time (min to h), but HL remains
- early in the disease: fluctuating SNHL
- later stages: persistent tinnitus and progressive HL
- attacks come in clusters and can be debilitating to the patient
- triggers: high salt intake, caffeine, stress, nicotine, and alcohol

Treatment
- acute management may consist of bed rest, antiemetics, antivertiginous drugs (e.g. betahistine (Serc®), meclizine, diphenhydramine), and anticholinergics (e.g. scopolamine)
- long-term management may include
  - medical
    - low salt diet, diuretics (e.g. hydrochlorothiazide, triamterene, amiloride)
    - Serc® prophylactically to decrease intensity of attacks
    - intratympanic gentamicin to destroy vestibular end-organ, results in complete SNHL
    - intratympanic glucocorticoids (e.g. dexamethasone) may improve vertigo symptoms
  - surgical
    - selective vestibular neurectomy or labyrinthectomy
    - potential benefit for endolymphatic sac decompression or sacculotomy
    - must monitor opposite ear, 35% of cases are bilateral

Vestibular Neuronitis (Labyrinthitis)

Definition
- acute onset of disabling vertigo often accompanied by N/V and imbalance without HL that resolves over days, leaving a residual imbalance that lasts days to weeks
- vestibular neuronitis: inflammation of the vestibular portion of CN VIII
- labyrinthitis: inflammation of both vestibular and cochlear portions

Etiology
- thought to be due to a viral infection (e.g. measles, mumps, herpes zoster) or post-viral syndrome
- only ~30% of cases have associated URTI symptoms
- labyrinthitis may occur as a complication of acute and chronic otitis media, bacterial meningitis, cholesteatoma, and temporal bone fractures

Clinical Features
- acute phase
  - severe vertigo with N/V and imbalance lasting 1-5 d
  - irritative nystagmus (fast phase towards the offending ear)
  - ataxia: patient tends to veer towards affected side
  - tinnitus and HL in labyrinthitis
- convalescent phase
  - imbalance and motion sickness lasting d-wk
  - spontaneous nystagmus away from affected side
  - gradual vestibular adaptation requires wk-mo

Drop Attacks (Tumarkin's Otolithic Crisis) are sudden falls occurring without warning and without loss of consciousness, where patient experiences feeling of being pushed down into the ground

Treatment
- acute phase
  - bed rest, antivertiginous drugs
  - corticosteroids (methylprednisolone) ± antivirals
  - bacterial infection: treat with IV antibiotics, drainage of middle ear, ± mastoidectomy
- convalescent phase
  - progressive ambulation, especially in the elderly
  - vestibular exercises: involve eye and head movements, sitting, standing, and walking

Before proceeding with gentamicin treatment, perform a gadolinium-enhanced MRI to rule out CPA tumour as the cause of symptoms

Acoustic Neuroma (Vestibular Schwannoma)

Definition
- schwannoma of the vestibular portion of CN VIII

Acoustic neuroma is the most common intracranial tumour causing SNHL and the most common CPA tumour

Pathogenesis
- tumour starts in the internal auditory canal and expands into CPA, compressing cerebellum and brainstem
- when associated with type 2 neurofibromatosis: bilateral acoustic neuromas, juvenile cataracts, meningiomas, and ependymomas

Clinical Features
- usually presents with unilateral SNHL (chronic) or tinnitus
- dizziness and unsteadiness may be present, but true vertigo is rare as tumour growth occurs slowly, allowing for compensation to occur
- facial nerve palsy and trigeminal (V1) sensory deficit (corneal reflex) are late complications
- risk factors: exposure to loud noise, childhood exposure to low-dose radiation, history of parathyroid adenoma

In the elderly, unilateral tinnitus or SNHL is acoustic neuroma until proven otherwise

Diagnosis
- MRI with gadolinium contrast (gold standard)
- audiogram (to assess SNHL)
- poor speech discrimination relative to the HL
- stapedial reflex absent or significant reflex decay
- ABR: increase in latency of the 5th wave
- vestibular tests: normal or asymmetric caloric weakness (an early sign)

Treatment
- expectant management if tumour is very small or in elderly
- definitive management is surgical excision
- other options: gamma knife, radiation

Tinnitus

Definition
- an auditory perception in the absence of an acoustic stimuli, likely related to loss of input into neurons in central auditory pathways, that results in abnormal firing

History
- subjective vs. objective (see Figure 14, OT7)
- pulsatile vs. nonpulsatile
- unilateral vs. bilateral
- associated symptoms: HL, vertigo, aural fullness, otalgia, otorrhea

Investigations
- physical examination: cranial nerve examination, otoscopy, auscultate for bruits over the neck, mastoid, and preauricular areas for pulsatile tinnitus
- audiology
- if pulsatile
  - magnetic resonance angiogram and venogram of the H&N to rule out vascular abnormalities
- if nonpulsatile and unilateral
  - non-contrast MRI

Treatment
- if a cause is found, treat the cause (e.g. drainage of middle ear effusion, embolization or excision of arteriovenous malformation)
- with no treatable cause: 15% will resolve, 20% will improve, 15% will worsen, 50% will remain the same
- primary and secondary prevention for SNHL (e.g. avoid high-volume music through headphones, ototoxic meds, smoking, high glycemic load, and hypercholesterolemia)
- conservative management (e.g. check zinc levels, improve sleep, reduce stress, reduce caffeine and alcohol consumption)
- sound amplification (e.g. hearing aids, white noise, tinnitus instrument)
- pharmacotherapy (e.g. melatonin)
  - consider tricyclic antidepressants and SSRI if comorbidities include anxiety and depression
- rehabilitation therapy
- surgical management (rare)

Diseases of the External Ear

Cerumen Impaction

Etiology
- ear wax: a mixture of secretions from ceruminous and pilosebaceous glands, squames of epithelium, dust, and debris

Risk Factors
- hairy or narrow ear canals, in-the-ear hearing aids, cotton swab usage, osteomata

Clinical Features
- CHL, tinnitus, fullness, itching, otalgia, discharge, odour, and cough

Treatment
- observation, cerumenolytic agents (water dissolves cerumen better than over-the-counter medications), irrigation, or manual removal

Cerumen impaction is the most common cause of CHL for those 15-50 y/o

Syringing

Indications
- Totally occlusive cerumen with pain, decreased hearing, or tinnitus

Contraindications
- Active infection
- Previous ear surgery
- Only hearing ear
- TM perforation

Complications
- OE
- TM perforation
- Trauma
- Pain
- Vertigo
- Tinnitus
- Otitis media

Method
- Establish that TM is intact
- Gently pull the pinna superiorly and posteriorly
- Using lukewarm water, aim the syringe nozzle upwards and posteriorly to irrigate the ear canal

Exostoses

Definition
- bony protuberances in the EAC composed of lamellar bone

Etiology
- possible association with swimming in cold water

Clinical Features
- usually an incidental finding
- can cause cerumen impaction or OE, if large

Treatment
- no Tx unless symptomatic (e.g. frequent OE, CHL)

Otitis Externa

Definition
- inflammation of EAC or auricle

Etiology
- bacterial (90% of OE): *Pseudomonas aeruginosa, Pseudomonas vulgaris, Escherichia coli, Staphylococcus aureus*
- fungal: *Candida albicans, Aspergillus niger*

Risk Factors
- anatomic abnormalities: canal stenosis, exostoses, hairy ear canal
- canal obstruction: cerumen, foreign body, sebaceous cyst
- epithelial integrity: cerumen removal, earplugs, hearing aids, instrumentation/itching
- dermatologic conditions: eczema, psoriasis, seborrhea
- water in ear canal: swimming, other prolonged water exposures

Clinical Features
- acute
  - otalgia, itching, fullness, ± HL, ± ear canal pain on chewing
  - tenderness aggravated by traction of pinna or pressure over tragus
  - ear canal edema, erythema, ± otorrhea, ± regional lymphadenitis, ± cellulitis of the pinna
- chronic
  - pruritus of external ear ± excoriation of ear canal
  - atrophic and scaly epidermal lining, ± otorrhea, ± HL
  - wide meatus, but no pain with movement of auricle
  - TM appears normal

Pulling on the pinna is extremely painful in OE, but is usually well tolerated in otitis media

Treatment
- microdebridement
- topical antimicrobials, topical antibiotics ± topical corticosteroids
  - antipseudomonal agents (e.g. ciprofloxacin) or a combination therapy (e.g. Ciprodex®)
  - ototoxic topical agents (e.g. gentamicin, neomycin, neomycin/polymyxin B/hydrocortisone) should not be used in a perforated TM

- keep the EAC dry
- oral antibiotics if the infection has spread beyond the ear canal
- ± analgesics for pain management
- chronic OE: treat the underlying cause (e.g. dermatologic conditions)

Malignant (Necrotizing) Otitis Externa (Skull Base Osteomyelitis)

Definition
- osteomyelitis of the mastoid or temporal bone

Epidemiology
- occurs in elderly patients with DM and immunocompromised patients

Etiology
- rare complication of OE
- most commonly caused by Pseudomonas aeruginosa

Clinical Features
- otalgia and purulent otorrhea that is refractory to medical therapy
- granulation tissue or necrotic tissue on the floor of the auditory canal

Complications
- cranial nerve palsy (most commonly CN VII>CN X>CN XI)
- systemic infection, death

Management
- imaging: high resolution temporal bone CT scan, gadolinium-enhanced MRI, technetium scan
- medical emergency: hospitalization, debridement, IV antibiotics
- may require OR for debridement of necrotic tissue/bone

Gallium and Technetium Scans
Gallium scans are used to show sites of active infection. Gallium is taken up by PMN, and therefore only lights up when active infection is present. It will not show the extent of osteomyelitis. Technetium scans provide information about osteoblastic activity and, as a result, are used to demonstrate sites of osteomyelitis. Technetium scans help with Dx, whereas gallium scans are useful in follow-up

Diseases of the Middle Ear

Acute Otitis Media and Otitis Media with Effusion

- see *Paediatric Otolaryngology*, OT39

Chronic Otitis Media

Definition
- an ear with TM perforation in the setting of recurrent or chronic ear infections

Benign
- dry TM perforation without active infection

Chronic Serous Otitis Media
- continuous serous drainage (straw-coloured)

Chronic Suppurative Otitis Media
- persistent purulent drainage through a perforated TM

Cholesteatoma

Definition
- a cyst composed of keratinized desquamated epithelial cells occurring in the middle ear, mastoid, and temporal bone
- two types: congenital and acquired

Congenital
- presents as a "small white pearl" behind an intact TM (anterior and medial to the malleus) or as CHL
- believed to be due to aberrant migration of external canal ectoderm during development
- not associated with otitis media/Eustachian tube dysfunction

Acquired (more common)
- primary cholesteatoma
  - frequently associated with retraction pockets in the pars flaccida, pars tensa, or both
  - a sequela of the dysfunction of the regulation of middle ear pressure
  - often has crusting or desquamated debris on lateral surface
- secondary cholesteatoma
  - "pearly mass" evident behind TM, frequently associated with marginal perforation
  - may appear as skin that has replaced the mucosa of the middle ear
- the associated chronic inflammatory process causes progressive destruction of surrounding bony structures

Mechanisms of Cholesteatoma Formation
- Epithelial migration through TM perforation (2° acquisition)
- Invagination of TM (1° acquisition)
- Metaplasia of middle ear epithelium or basal cell hyperplasia (congenital)

Clinical Features
- history of otitis media (especially if unilateral), ventilation tubes, ear surgery
- symptoms
  - progressive HL (predominantly conductive, although may get SNHL in late stage)
  - otalgia, aural fullness, fever
- signs
  - retraction pocket in TM, may contain keratinous debris
  - TM perforation
  - granulation tissue, polyp visible on otoscopy
  - malodourous, unilateral otorrhea

Complications

Table 8. Complications of Cholesteatoma

Local	Intracranial
Ossicular erosion: CHL	Meningitis
Inner ear erosion: SNHL, dizziness, and/or labyrinthitis	Sigmoid sinus thrombosis
Temporal bone infection: mastoiditis, petrositis	Intracranial abscess (subdural, epidural, cerebellar)
Facial paralysis	

Investigations
- audiogram and non-contrast CT

Treatment
- surgical: mastoidectomy ± tympanoplasty ± ossicular reconstruction

Mastoiditis

Definition
- infection (usually subperiosteal) of mastoid air cells, most commonly seen approximately two wk after onset of untreated or inadequately treated AOM (suppurative)
- more common in children than adults

Etiology
- acute mastoiditis is caused by the same organisms as AOM: *S. pneumoniae, H. influenzae, M. catarrhalis, S. pyogenes, S. aureus, P. aeruginosa*, etc.

Classic Triad
- Otorrhea
- Tenderness to pressure over the mastoid
- Retroauricular swelling with protruding ear

Clinical Features
- otorrhea
- tenderness to pressure over the mastoid
- retroauricular swelling with protruding ear
- fever, HL, ± TM perforation (late)
- CT radiologic findings: opacification of mastoid air cells by fluid and interruption of normal trabeculations of cells (coalescence)

Complications of AOM are rare due to rapid and effective treatment of AOM with antibiotics

Treatment
- IV antibiotics with myringotomy and ventilation tubes – usually all that is required in acute cases
- may require additional incision and drainage of postauricular abscess
- cortical mastoidectomy
  - debridement of infected tissue allowing aeration and drainage
- indications for surgery
  - failure of medical treatment after 48 h
  - symptoms of intracranial complications
  - aural discharge persisting for 4 wk and resistant to antibiotics

Otosclerosis

Definition
- fusion of stapes footplate to oval window such that it cannot vibrate

Etiology
- autosomal dominant, variable penetrance approximately 40%
- F>M, progresses during pregnancy (hormone responsive)

Otosclerosis is the 2nd most common cause of CHL in 15-50 y/o (after cerumen impaction)

Clinical Features
- progressive CHL first noticed in teens and 20s (may progress to SNHL if cochlea involved)
- ± nonpulsatile tinnitus
- TM normal ± pink blush (Schwartz's sign) associated with the neovascularization of otosclerotic bone
- characteristic dip at 2000 Hz (Carhart's notch) on audiogram (see Figure 16C, OT10)

Treatment
- monitor with serial audiograms if coping with loss
- hearing aid (AC, BC, BAHA)
- stapedectomy or stapedotomy (with laser or drill) with prosthesis is definitive treatment

Diseases of the Inner Ear

Congenital Sensorineural Hearing Loss

Hereditary Defects
- non-syndrome associated (70%)
  - often idiopathic, autosomal recessive
  - connexin 26 (GJB2) most common
- syndrome associated (30%)
  - Waardenburg: white forelock, heterochromia iridis (each eye different colour), wide nasal bridge, and increased distance between medial canthi
  - Pendred: euthyroid goiter, SLC26A4 gene, enlarged vestibular aqueducts
  - Treacher-Collins: first and second branchial cleft anomalies
  - Alport: hereditary nephritis

Risk Factors for Neonatal Sensorineural Hearing Loss
- family history of permanent HL
- craniofacial abnormality
- prenatal infections
  - TORCH: toxoplasmosis, other (syphilis, varicella-zoster, parvovirus B19), rubella, CMV, HSV
  - Zika
- postnatal infections
  - bacterial meningitis, mumps, measles
- neonatal intensive care unit stay >2 d
- extracorporeal membrane oxygenation at birth
- assisted ventilation at birth/perinatal anoxia, birth trauma (hemorrhage into inner ear)
- ototoxic drug use
- hyperbilirubinemia requiring exchange transfusion

Treatment
- presence of any risk factor: ABR study performed before leaving NICU and at 3 mo adjusted age
- early rehabilitation improves speech and school performance

Presbycusis

Definition
- SNHL associated with aging (starting in 5th and 6th decades)

Presbycusis is the most common cause of SNHL

Etiology
- hair cell degeneration
- age-related degeneration of basilar membrane, possibly genetic etiology
- cochlear neuron damage
- ischemia of inner ear

Clinical Features
- progressive, bilateral hearing deterioration initially at high frequencies, followed by middle and lower frequencies

- loss of discrimination of speech, especially with background noise present – patients describe people as mumbling
- recruitment phenomenon: inability to tolerate loud sounds
- tinnitus

Treatment
- hearing aid if patient has difficulty functioning, HL >30-35 dB, and good speech discrimination
- ± lip reading, auditory training, auditory aids (doorbell and phone lights)

Sudden Sensorineural Hearing Loss

Etiology
- usually idiopathic (80-90% of cases); rule out other causes
  - autoimmune
  - infectious (e.g. EBV, group *A Streptococcus*, HSV, herpes-zoster virus, HIV, Lyme disease, meningitis, syphilis)
  - trauma
  - vascular (e.g. cerebrovascular disease)
  - neoplastic (e.g. angioma, meningioma, neurofibromatosis 2, schwannoma)
  - other (e.g. ototoxins, pregnancy)

Sudden SNHL may easily be confused with ischemic brain events. It is important to keep a high index of suspicion especially with elderly patients presenting with sudden SNHL, as well as vertigo

Clinical Features
- presents as a sudden onset of significant SNHL (usually unilateral) ± tinnitus, vertigo, aural fullness

Treatment
- treat the underlying cause
- MRI to rule out tumour and/or CT to rule out ischemic/hemorrhagic stroke if associated with any other focal neurological signs (e.g. vertigo, ataxia, abnormality of CN V or VII, weakness)
- if idiopathic, intratympanic or oral corticosteroids (prednisone 1 mg/kg/d for 7-14 d). Start within 3 d (most ideal) up to 14 d after onset

Clinical Practice Guideline: Sudden Hearing Loss
Otolaryngol Head Neck Surg 2019 Aug;161
Recommendations Based on Findings:
- Confirm HL is sensorineural with audiometric testing (loss of at least 30 dB affecting three consecutive frequencies)
- Routine labs, CT, or MRI not required unless indicated by history and physical
- Initiate steroid treatment within 14 d of symptom onset

Prognosis
- depends on degree of HL
- 70% resolve within 10-14 d
- 20% experience partial resolution
- 10% experience permanent HL

Autoimmune Inner Ear Disease

Etiology
- idiopathic
- may be associated with systemic autoimmune diseases (e.g. RA, SLE), vasculitides (e.g. GPA, polyarteritis nodosa), and allergies

Epidemiology
- most common between ages 20-50

Clinical Features
- rapidly progressive or fluctuating bilateral SNHL
- ± tinnitus, aural fullness, vestibular symptoms (e.g. ataxia, disequilibrium, vertigo)

Investigations
- autoimmune workup: CBC, ESR, ANA, rheumatoid factor

Treatment
- high-dose corticosteroids: treat early for at least 30 d
- consider cytotoxic medication for steroid non-responders

Drug Ototoxicity

Aminoglycosides
- streptomycin and gentamicin (vestibulotoxic), kanamycin, and tobramycin (cochleotoxic)
- toxic to hair cells by any route: oral, IV, and topical (if the TM is perforated)
- destroys sensory hair cells: outer first, inner second (therefore, otoacoustic emissions are lost first)
- high frequency HL develops earliest
- ototoxicity occurs d-wk post-treatment
- must monitor with peak and trough levels when prescribed, especially if patient has neutropenia and/or history of ear or renal problems

- q24 h dosing recommended (with amount determined by creatinine clearance)
- aminoglycoside toxicity displays saturable kinetics, therefore, once daily dosing presents less risk than divided daily doses
- duration of treatment is the most important predictor of ototoxicity
  - treatment: immediately stop aminoglycosides

Analgesics and Antipyretics
- acetaminophen, NSAIDS, and salicylates
- HL with tinnitus, reversible if discontinued

Others
- antineoplastic agents (e.g. bleomycin)
- loop diuretics (e.g. furosemide) and antimalarials (e.g. quinine)
  - reversible by decreasing or stopping medications

Noise-Induced Sensorineural Hearing Loss

Pathogenesis
- 85-90 dB over mo or yr, single sound impulses >135 dB, or repetitive vibratory insults (e.g. jackhammer) can cause cochlear damage
- bilateral SNHL initially and most prominently at 4000 Hz (resonant frequency of the temporal bone), known as "boilermaker's notch" on audiogram, extends to higher and lower frequencies with time (see Figure 16D, OT10)
- speech reception not altered until HL >30 dB at speech frequency, therefore considerable damage may occur before patient complains of HL
- difficulty with speech discrimination, especially in situations with competing noise

Phases of Hearing Loss
- dependent on: intensity of sound and duration of exposure
  - temporary threshold shift
    - when exposed to loud sound, decreased sensitivity or increased threshold for sound
    - may have associated aural fullness and tinnitus
    - hearing returns to normal with removal of noise
  - permanent threshold shift
    - hearing does not return to previous state

Treatment
- hearing aid
- prevention
  - ear protectors: muffs, plugs
  - limit exposure to noise with frequent rest periods
  - regular audiologic follow-up

Temporal Bone Fractures

Table 9. Features of Temporal Bone Fractures

	Otic Capsule Involving (1)	Otic Capsule Sparing (2)
Extension	Into bony labyrinth and internal auditory meatus	Into middle ear
Incidence	10-20%	70-90%
Etiology	Frontal/occipital trauma	Lateral skull trauma
CN Pathology	CN VII palsy (50%)	CN VII palsy (10-20%)
Hearing Loss	SNHL due to direct cochlear injury	CHL 2° to ossicular injury
Vestibular Symptoms	Sudden onset vestibular symptoms due to direct semicircular canal injury (vertigo, spontaneous nystagmus)	Rare
Other Features	Intact external auditory meatus, TM ± hemotympanum Spontaneous nystagmus CSF leak in Eustachian tube to nasopharynx ± rhinorrhea (risk of meningitis)	Torn TM or hemotympanum Bleeding from EAC Step formation in EAC CSF otorrhea Battle's sign = mastoid ecchymosis Raccoon eyes = periorbital ecchymosis

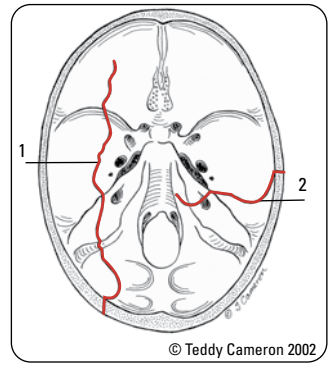

Figure 18. Types of temporal bone fractures

- characterized as longitudinal or transverse relative to the long axis of the petrous temporal bone
- temporal bone fractures are rarely purely transverse or longitudinal (often a mixed picture)

Diagnosis
- otoscopy
  - do not syringe or manipulate external auditory meatus due to risk of inducing meningitis via TM perforation
- CT head
- audiology, facial nerve tests (for transverse fractures), Schirmer's test (of lacrimation), stapedial reflexes if CN VII palsy
- if suspecting CSF leak: look for halo sign, send fluid for β-2 transferrin or β-trace protein (prostaglandin D synthase)

Signs of Basilar Skull Fracture
- Battle's sign (bruising over mastoid)
- Racoon eyes (periorbital ecchymosis)
- CSF rhinorrhea/otorrhea
- Cranial nerve involvement:
  - facial palsy → CN VII;
  - nystagmus → CN VI;
  - facial numbness → CN V

Treatment
- ABCs
- medical: expectant, prevent otogenic meningitis
- surgical: explore temporal bone; indications:
  - CN VII palsy (immediate and complete)
  - gunshot wound
  - depressed fracture of external auditory meatus
  - early meningitis (mastoidectomy)
  - bleeding intracranially from sinus
  - CSF otorrhea (may resolve spontaneously)

Complications
- AOM ± labyrinthitis ± mastoiditis
- meningitis/epidural abscess/brain abscess
- post-traumatic cholesteatoma

Facial Nerve (CN VII) Paralysis

Peripheral Facial Paralysis (PFP)
- mononeuropathy of the facial nerve where there is weakening in the facial muscles, which alters facial symmetry and functions
- can have a detectable cause (secondary) or may be idiopathic (primary)

Etiology
- metabolic disease (e.g. diabetes, preeclampsia)
- stroke (e.g. ipsilateral pontine infarction)
- infection (e.g. otitis media, mastoiditis, HSV, varicella-zoster virus)
- trauma
- tumour
- immune disorder (e.g. Guillain-Barré syndrome, myasthenia gravis)
- drugs
- idiopathic

Treatment
- treat according to etiology; provide corneal protection with artificial tears, nocturnal lid taping, tarsorrhaphy, gold weighting of upper lid
- if idiopathic, corticosteroids ± antivirals in patients with severe to complete paresis
- facial paralysis that does not resolve with time or with medical treatment will often be referred for reanimation techniques to restore function
  - common reanimation techniques include:
    - direct facial nerve anastomosis
    - interpositional grafts
    - anastomosis to other motor nerves
    - muscle transpositions

Table 10. Differential Diagnosis of Peripheral Facial Paralysis (PFP)

Etiology	Incidence	Findings	Investigations	Treatment, Follow-up, and Prognosis (Px)
Bell's Palsy Idiopathic, (HSV) infection of the facial nerve Diagnosis of exclusion	4.5-9% of PFP **Risk Factors:** >60 yr Impaired immunity Cancer Radiotherapy Chemotherapy	**Hx** Acute onset Numbness of ear Schirmer's test Recurrence (12%) + FHx (14%) Hyperacusis (30%) **P/E** Paralysis or paresis of all muscle groups on one side of the face Absence of signs of CNS disease Absence of signs of ear or CPA diseases Absence of signs of an upper motor neuron lesion or CVA	Stapedial reflex absent Audiology normal (or baseline) EMG — best measure for prognosis Topognostic testing MRI with gadolinium — enhancement of CN VII and VIII High resolution CT	**Rx** Protect the eye to prevent exposure keratitis with patching or tarsorrhaphy Systemic steroids may lessen degeneration and hasten recovery Consider antiviral (acyclovir) **F/U** Spontaneous remission should begin within 3 wk of onset Delayed (3-6 mo) recovery portends at least some functional loss **Px** Poorer if hyperacusis, >60 yr, DM, HTN, severe pain
Ramsay Hunt Syndrome (Herpes Zoster Oticus) Varicella zoster infection of CN VII/VIII	4.5-9% of PFP **Risk Factors:** >60 yr Impaired immunity Cancer Radiotherapy Chemotherapy	**Hx** Hyperacusis SNHL Severe pain of pinna, mouth, or face **P/E** Vesicles on pinna, external canal (erupt 3-7 d after onset of pain) Associated herpes zoster ophthalmicus (uveitis, keratoconjunctivitis, optic neuritis, or glaucoma)	Stapedial reflex absent Audiology — SNHL Viral ELISA studies to confirm MRI with gadolinium (86% of facial nerves enhanced)	**Rx** Avoid touching lesions to prevent spread of infection Systemic steroids can relieve pain, vertigo, avoid postherpetic neuralgia Acyclovir may lessen pain, aid healing of vesicles **F/U:** 2-4 wk **Px** Worse prognosis than Bell's palsy; 22% recover completely, 66% incomplete paralysis, 10% complete paralysis
TEMPORAL BONE FRACTURE	***a patient rarely has a single type of fracture**			
Otic Capsule Sparing (90%)	20% have PFP	**Hx** Blow to side of head **P/E** Trauma to side of head Neuro findings consistent with epidural/subdural bleed	Skull x-rays CT head	**Px** Injury usually due to stretch or impingement; may recover with time
Otic Capsule Involving (10%)	40% have PFP	**Hx** Blow to frontal or occipital area **P/E** Trauma to front or back of head	Skull x-rays CT head	**Px** Nerve transection more likely
Iatrogenic		Variable (depending on level of injury)	Wait for lidocaine to wear off EMG	**Rx** Exploration if complete nerve paralysis No exploration if any movement present

Source: Paul Warrick, MD

Rhinitis

Definition
- inflammation of the lining (mucosa) of the nasal cavity

Table 11. Classification of Rhinitis

Inflammatory	Non-Inflammatory
Perennial non-allergic	Rhinitis medicamentosa
Asthma, ASA sensitivity	Topical decongestants
Allergic	Hormonal
Seasonal	Pregnancy
Perennial	Estrogens
Atrophic	Thyroid
Primary: *Klebsiella ozena* (especially in elderly)	Idiopathic vasomotor
Acquired: post-surgery if too much mucosa or turbinate has been resected	
Infectious	
Viral: rhinovirus, influenza, parainfluenza, etc.	
Bacterial: *S. aureus*	
Fungal	
Granulomatous: TB, syphilis, leprosy	
Non-infectious	
Sarcoidosis	
GPA	
Irritant	
Dust	
Chemicals	
Pollution	

Rhinitis medicamentosa: rebound congestion due to the overuse of intranasal vasoconstrictors; for prevention, use of these medications for only 5 d is recommended. Treat with intranasal steroid

Table 12. Nasal Discharge: Character and Associated Conditions

Character	Associated Conditions
Watery/Mucoid	Allergic, viral, vasomotor, CSF leak (halo sign)
Mucopurulent	Bacterial, foreign body
Serosanguinous	Neoplasia
Bloody	Trauma, neoplasia, bleeding disorder, HTN/vascular disease

Allergic Rhinitis (i.e. Hay Fever)

Definition
- rhinitis characterized by an IgE-mediated hypersensitivity to foreign allergens
- acute-and-seasonal or chronic-and-perennial
- perennial allergic rhinitis often confused with recurrent colds

Congestion reduces nasal airflow and allows the nose to repair itself (i.e. washes away the irritants). Treatment should focus on the initial insult rather than target this defense mechanism

Etiology
- when allergens contact the respiratory mucosa, specific IgE antibody is produced in susceptible hosts
- concentration of allergen in the ambient air correlates with the rhinitis symptoms

Epidemiology
- age at onset usually <20 yr
- personal or family history of atopic disease

Clinical Features
- nasal congestion, nasal itch, rhinorrhea, and sneezing
- ± allergic conjunctivitis (redness, tearing, itching of the eyes)
- mucosal swelling and bleeding, pale and thin nasal secretion, ± nasal polyps
- seasonal
  - caused by pollen from trees, grass, and ragweed
  - occurs during a specific season
- perennial
  - caused by airborne dust mite fecal particles, cockroach residues, animal dander, moulds, and tobacco smoke
  - occurs throughout the yr

Complications
- chronic sinusitis/polyps
- serous otitis media

Diagnosis
- history
- physical exam
- allergy testing

Treatment
- allergen identification and avoidance
- nasal saline irrigation
- oral antihistamine (e.g. desloratadine, fexofenadine, loratadine, cetirizine)
- intranasal corticosteroid (mainstay of treatment)
- combination intranasal corticosteroid/antihistamine spray
- leukotriene receptor antagonist
- allergen immunotherapy
- other therapies: decongestants (risk of rhinitis medicamentosa), oral corticosteroids, eye drops

Nonallergic Rhinopathy (i.e. Vasomotor Rhinitis)

Definition
- dysregulation of nociceptors and autonomic nerves

Etiology
- temperature change
- alcohol, dust, smoke
- stress, anxiety, neurosis

Clinical Features
- chronic intermittent nasal obstruction, varies from side to side
- thin, watery rhinorrhea
- swollen mucosa and turbinates
- nasal allergy must be ruled out

Treatment
- elimination of irritant factors
- congestion-predominant:
  - intranasal antihistamine
  - intranasal corticosteroid
  - combination INCS/antihistamine
  - ± oral decongestant (risk of rhinitis medicamentosa)
- rhinorrhea-predominant:
  - intranasal anticholinergic (e.g. ipratropium)
  - ± intranasal corticosteroid, intranasal antihistamine
- symptomatic relief with exercise (increased sympathetic tone)

Rhinosinusitis

Definition
- inflammation of the mucosal lining of the sinuses and nasal passages

Pathogenesis of Rhinosinusitis
- ostial obstruction or dysfunctional cilia permit stagnant mucous and, consequently, infection
- all sinuses drain into a common area under the middle meatus called the osteomeatal complex

Classification
- acute: <4 wk
- chronic: >12 wk

Table 13. Etiologies of Rhinosinusitis

Ostial Obstruction	Inflammation	URTI Allergy
	Mechanical	Septal deviation Turbinate hypertrophy Polyps Tumours Adenoid hypertrophy Foreign body Congenital abnormalities (e.g. cleft palate)
	Immune	GPA Lymphoma, leukemia Immunosuppressed patients (e.g. neutropenics, diabetics, HIV)
Systemic		Cystic fibrosis Immotile cilia (e.g. Kartagener's syndrome)
Direct Extension	Dental	Infection
	Trauma	Facial fractures

Acute Bacterial Rhinosinusitis

Definition
- bacterial infection of the paranasal sinuses and nasal passages lasting >7 d
- clinical diagnosis requiring ≥2 major symptoms, and at least one of the symptoms is either nasal obstruction or purulent/discoloured nasal discharge

	Major Symptoms (at least 2 of PODS, 1 must be O or D)	Minor Symptoms
P	Facial **P**ain/**P**ressure/fullness	Headache
O	Nasal **O**bstruction	Halitosis
D	Purulent/discoloured nasal **D**ischarge	Fatigue
S	Hyposmia/anosmia (**S**mell)	Dental pain
		Cough
		Ear pain/fullness

Etiology
- bacteria: *S. pneumoniae* (35%), *H. influenzae* (35%), *M. catarrhalis, S. aureus*, anaerobes (dental)
- children are more prone to a bacterial etiology, but viral is still more common
- the maxillary sinus is the most commonly affected sinus
- must rule out fungal causes (mucormycosis) in immunocompromised hosts (especially if painless black or pale mucosa on examination)

Clinical Features
- sudden onset of:
  - nasal blockage/congestion and/or purulent nasal discharge/posterior nasal drip
  - ± facial pain or pressure, ±hyposmia, ±sore throat
- persistent symptoms >10 d or worsening symptoms >5 d or presence of purulence for 3-4 d with high fever (>39°C)
- speculum exam: erythematous mucosa, mucopurulent discharge, pus originating from the middle meatus
- predisposing factors: viral URTI, allergy, dental disease, anatomical defects
- differentiate from acute viral rhinosinusitis (course: <10 d, peaks by day 3)

Diagnosis
- along with clinical criteria, can confirm radiographically and/or endoscopically using antral puncture for bacterial cultures

Management
- depends on symptom severity (i.e. intensity/duration of symptoms, impact on quality of life)
- mild-moderate: INCS
  - if no response within 72 h, add antibiotics
- severe: INCS + antibiotics
- antibiotics
  - 1st line: amoxicillin x 10 d (TMP-SMX or macrolide if penicillin allergy)
- if no response to 1st line antibiotics within 72 h, switch to 2nd line
  - 2nd line: fluoroquinolones or amoxicillin-clavulanic acid
- adjuvant therapy (saline or hypochlorous acid (paediatric sinusitis) irrigation, analgesics, oral/topical decongestant) may provide symptomatic relief
- CT indicated only if complications are suspected

Acute Rhinosinusitis Complications
Consider hospitalization if any of the following are suspected:

Orbital (Chandler's classification)
- I Preseptal cellulitis
- II Orbital cellulitis
- III Subperiosteal abscess
- IV Orbital abscess
- V Cavernous sinus thrombosis

Intracranial
- Meningitis
- Abscess

Bony
- Subperiosteal frontal bone abscess ("Pott's puffy tumour")
- Osteomyelitis

Neurologic
- Superior orbital fissure syndrome (CN III/IV/VI palsy, immobile globe, dilated pupils, ptosis, V1 hypoesthesia)
- Orbital apex syndrome (as above, plus neuritis, papilledema, decreased visual acuity)

Systemic Corticosteroid Therapy for Acute Sinusitis
JAMA 2015 Mar;313(12):1258-1259
Clinical Question: Are oral or parenteral corticosteroids associated with improved clinical outcomes in patients with acute sinusitis compared to placebo or NSAIDs?
Conclusion: Oral corticosteroids combined with antibiotics may be associated with modest benefit for short-term relief of symptoms in adults with severe symptoms of acute sinusitis compared with antibiotics alone. Oral corticosteroids as monotherapy are not associated with improved clinical outcomes in adults with clinically diagnosed acute sinusitis.

Chronic Rhinosinusitis

Definition
- inflammation of the mucosa of paranasal sinuses and nasal passages >12 wk
- diagnosis requires ≥2 major symptoms for >12 wk and ≥1 objective finding of inflammation of the paranasal sinuses (CT/endoscopy)

	Major Symptoms (similar to acute, but less severe)	Minor Symptoms
C	Facial **C**ongestion/fullness	Halitosis
P	Facial **P**ain/Pressure/fullness	Chronic cough
O	Chronic nasal **O**bstruction	Maxillary dental pain
D	Purulent anterior/posterior nasal **D**ischarge	
S	Hyposmia/anosmia (**S**mell)	

Etiology

- unclear etiology but the following may contribute or predispose
  - inadequate treatment of acute rhinosinusitis
  - untreated dental disease
  - anatomic factors (lost ostium patency, deviated septum)
  - local physiologic factors
    - ciliary disorder (e.g. cystic fibrosis, Kartagener syndrome, primary ciliary dyskinesia)
    - bacterial colonization/biofilms (*S. aureus, Enterobacteriaceae* spp., *Pseudomonas* spp., *S. pneumoniae*, group A β-hemolytic *Streptococcus*)
    - fungal infection (e.g. *Aspergillus, Zygomycetes, Candida*)
  - systemic physiologic factors
    - allergy/allergic rhin, oral steroids ± antibiotics (if signs of infection), refer to otolaryngologist/H&N surgeon
- if polyps absent: INCS, antibiotics, saline irrigation, oral steroids (severe cases)
- antibiotics for 3-6 wk
  - amoxicillin-clavulanic acid, fluoroquinolone (moxifloxacin), macrolide (clarithromycin), clindamycin (metronidazole)
- surgery if medical therapy fails or fungal sinusitis: ESS, balloon sinuplasty

Allergic Fungal Rhinosinusitis
- A chronic sinusitis affecting mostly young, immunocompetent, atopic individuals
- Treatment options include FESS ± intranasal topical steroids, antifungals, and immunotherapy

Complications

- same as acute sinusitis, mucocoele

ESS = Endoscopic Sinus Surgery
Opening of the entire osteomeatal complex in order to facilitate drainage while sparing the sinus mucosa

Epistaxis

Blood Supply to the Nasal Septum (see Figure 4, OT3)

1. superior posterior septum
   - internal carotid ➔ ophthalmic ➔ anterior/posterior ethmoidal
2. posterior septum
   - external carotid ➔ internal maxillary ➔ sphenopalatine ➔ nasopalatine
3. lower anterior septum
   - external carotid ➔ facial artery ➔ superior labial artery ➔ nasal branch
   - external carotid ➔ internal maxillary ➔ descending palatine ➔ greater palatine

- these arteries all anastomose to form Kiesselbach's plexus, located at Little's area (anterior-inferior portion of the cartilaginous septum)
- bleeds originative above the middle turbinate are from the internal carotid, and bleeds originative from below the middle turbinate are from the external carotid
- 80-90% of bleeds are anterior

90% of nosebleeds occur in Little's area

Table 14. Etiology of Epistaxis

Type	Causes	
Primary Epistaxis	Idiopathic or spontaneous	
Secondary Epistaxis		
Local	Trauma (most common) Fractures: facial, nasal Self-induced: digital, foreign body	Tumours Benign: polyps, inverting papilloma, angiofibroma Malignant: SCC, esthesioneuroblastoma (olfactory neuroblastoma)
	Iatrogenic: nasal, sinus, orbit surgery	Inflammation Rhinitis: allergic, non-allergic Infections: bacterial, viral, fungal
	Nasal dryness: dry air, supplemental nasal oxygen	
	Structural abnormalities: septal deviation, chronic septal perforation	
	Chemical: nasal cocaine, nasal sprays, etc.	
Systemic	Coagulopathies Medications: anticoagulants, NSAIDs Hemophilias, von Willebrand disease Hematological malignancies Liver failure, uremia	
	Vascular: HTN, atherosclerosis, Osler-Weber-Rendu disease (hereditary hemorrhagic telangiectasia)	
	Others: GPA, SLE	

Special Cases
- Adolescent male with unilateral recurrent epistaxis: consider juvenile nasopharyngeal angiofibroma (JNA); this is the most common benign tumour of the nasopharynx
- Thrombocytopenic patients: use resorbable packs to avoid risk of re-bleeding caused by pulling out the removable pack

Investigations

- CBC, PT/PTT/INR/platelet function assay (if suspicious of bleeding disorder)
- CT as needed

Treatment

- locate bleeding and achieve hemostasis

1. ABCs
- lean patient forward to minimize swallowing blood and avoid airway obstruction
- apply constant firm pressure for 15 to 20 min on cartilaginous part of nose (not bony pyramid) while the head is in neutral position
- if significant bleeding, assess vitals for signs of hemorrhagic shock ± IV NS, cross-match blood

2. Determine Site of Bleeding
- anterior/posterior hemorrhage defined by location in relationship to bony septum
- visualize nasal cavity with speculum
- use cotton pledget with topical lidocaine ± topical decongestant (i.e. Otrivin®) to help identify area of bleeding (often anterior septum)

3. Control the Bleeding
- first-line: topical vasoconstrictors (Otrivin®)
- if first-line fails and bleeding adequately visualized, cauterize with silver nitrate
- **do not cauterize both sides of the septum** at one time due to risk of septal perforation from loss of septal blood supply

A. Anterior hemorrhage treatment
- if failure to achieve hemostasis with cauterization
  - place anterior pack with expandable nasal tampons (Merocel®) or fabric sponges (Rapid Rhino Riemann)*
  - consider lubricated absorbable packing (i.e. Gelfoam wrapped in Surgicel®) for patients with coagulopathy or on anticoagulation medication to prevent recurrent epistaxis from packing removal
  - alternatively, use a half inch Vaseline®-soaked ribbon gauze strips layered from nasal floor toward nasal roof and extending to posterior choanae
  - can also apply Floseal® (hemostatic matrix consisting of topical human thrombin and cross-linked gelatin) if other methods fail

B. Posterior hemorrhage treatment
- if unable to visualize bleeding source, the source is likely posterior
  - place posterior pack* using a Foley catheter, gauze pack, or Epistat® balloon
  - subsequently, layer anterior packing bilaterally
  - admit to hospital with packs in for 3-5 d
  - watch for complications: hypoxemia (nasopulmonary reflex), toxic shock syndrome (remove packs immediately), pharyngeal fibrosis/stenosis, alar/septal necrosis, aspiration

C. If anterior/posterior packs fail to control epistaxis
- transnasal endoscopic sphenopalatine artery ligation +/- anterior ethmoid artery ligation by otolaryngology or embolization of culprit arterial supply by interventional radiology
- ± septoplasty

*antibiotics for any posterior pack or any pack left for >48 h due to risk of toxic shock syndrome

4. Prevention
- prevent drying of nasal mucosa with humidifiers, saline spray, or topical ointments
- avoidance of irritants
- medical management of HTN and coagulopathies

Hoarseness

Definitions
- hoarseness: change in voice quality, ranging from voice harshness to voice weakness; reflects abnormalities anywhere along the vocal tract from oral cavity to the lungs
- dysphonia: a general alteration in voice quality
- aphonia: no sound emanates from vocal folds

Acute Laryngitis

Definition
- <2 wk inflammatory changes in laryngeal mucosa after exposure to a trigger

Etiology
- infectious (most common): viral (influenza, adenovirus, HSV), bacterial (Group A *Streptococcus*), fungal
- mechanical: acute voice strain ➔ submucosal hemorrhage ➔ vocal cord edema ➔ hoarseness
- environmental: toxic fume inhalation

Clinical Features
- URTI symptoms, hoarseness, aphonia, cough attacks
- true vocal cords erythematous/edematous with vascular injection and normal mobility

If hoarseness is present for >2 wk in a smoker, laryngoscopy must be done to rule out malignancy

Vocal Cord Paralysis
- **Unilateral**: Affected cord lies in the paramedian position, inadequate glottic closure during phonation ➔ weak, breathy voice. Usually medializes with time, whereby phonation and aspiration improve. Treatment options include voice therapy, injection laryngoplasty (Radiesse), medialization using silastic block, recurrent laryngeal nerve reinnervation (RLN anastomosis to ansa cervicalis)
- **Bilateral**: Cords rest in midline, therefore voice remains unchanged but respiratory function is compromised and may present as stridor. If no respiratory issues, monitor closely and wait for improvement. If respiratory issues, try CPAP or intubate if necessary. The patient will likely require vocal cord lateralization, arytenoidectomy, posterior costal cartilage graft, or tracheotomy. Selective nerve reinnervation (Marie Technique) in the proper hands may reestablish movement

Treatment
- usually self-limited, resolves within 1-2 wk
- voice rest
- humidification
- hydration
- avoid irritants (e.g. smoking, caffeine)
- treat with antibiotics if there is evidence of coexistent bacterial pharyngitis
- treat with proton pump inhibitors if there is evidence of reflux

Chronic Laryngitis

Definition
- >3 wk inflammatory changes in laryngeal mucosa

Etiology
- repeated attacks of acute laryngitis
- infectious: chronic rhinosinusitis with postnasal drip
- mechanical: chronic voice strain
- environmental: chronic irritants (dust, smoke, chemical fumes), chronic alcohol use
- esophageal disorders: GERD, Zenker's diverticulum, hiatus hernia
- systemic: allergy, hypothyroidism, Addison's disease

Clinical Features
- chronic dysphonia
- cough, globus sensation, frequent throat clearing 2° to GERD
- laryngoscopy: erythematous and thickened cords with ulceration/granuloma formation and normal mobility, rule out malignancy

Treatment
- remove offending irritants
- treat related disorders (e.g. antisecretory therapy for GERD)
- speech therapy with vocal rest
- ± antibiotics ± steroids to decrease inflammation

Vocal Cord Polyps

Definition
- structural manifestation of vocal cord irritation
- acutely, polyp forms 2° to capillary damage in the subepithelial space during extreme voice exertion

Etiology
- most common benign tumour of vocal cords
- voice strain (i.e. muscle tension dysphonia)
- laryngeal irritants (i.e. GERD, allergies, tobacco)

Epidemiology
- ages 30-50 y/o
- M>F

Clinical Features
- primary symptom is dysphonia ± dyspnea (if polyps are large)
- other symptoms: hoarseness, aphonia, cough attacks
- pedicled or sessile polyp on free edge of vocal cord
- typically, polyp is asymmetrical, soft, and smooth
- more common on the anterior 1/3 of the vocal cord

Treatment
- avoid irritants
- voice therapy may improve voice
- vocal fold steroid injections (percutaneous or transoral)
- endoscopic laryngeal microsurgical removal if persistent or if high-risk of malignancy

Vocal Cords: Polyps vs. Nodules

Polyps	Nodules
Unilateral, asymmetric	Bilateral
Acute onset	Gradual onset
May resolve spontaneously	Often follow a chronic course
Subepithelial capillary breakage	Acute: submucosal hemorrhage or edema Chronic: hyalinization within submucosal lesion
Soft, smooth, fusiform, pedunculated mass	Acute: small, discrete nodules Chronic: hard, white, thickened, fibrosed nodules
Proton pump inhibitor	Vocal rest with whispering, hydration, voice therapy
Surgical excision if persistent or in the presence of risk factors for laryngeal cancer	Surgical excision as last resort

Vocal Cord Nodules

Definition
- vocal cord callus
- i.e. "screamer's" or "singer's" nodules

Etiology
- early nodules occur 2° to submucosal hemorrhage
- mature nodules result from hyalinization, which occurs with long-term voice abuse
- chronic voice strain
- frequent URTI, smoking, alcohol consumption

Epidemiology
- frequently in singers, children, bartenders, and school teachers
- F>M

Clinical Features
- hoarseness worst at end of day
- on laryngoscopy
  - often bilateral
  - at the junction of the anterior 1/3 and posterior 2/3 of the vocal cords – point of maximal cord vibration
- chronic nodules may become fibrotic, hard, and white

Treatment
- primary treatment is voice rest and voice therapy
- hydration
- avoid irritants
- surgery rarely indicated for refractory nodules

Benign Laryngeal Papillomatosis

Etiology
- most commonly HPV types 6, 11, but can be caused by types 16, 18, 31, 33
- possible hormonal influence, possibly acquired during delivery

Epidemiology
- biphasic distribution
  - birth to puberty (most common laryngeal tumour)
  - adulthood

Clinical Features
- progressive hoarseness, stridor, and respiratory distress; less commonly wheezing, chronic cough, recurrent pneumonia, dyspnea, hemoptysis, dysphagia, failure to thrive, apneic events
- can seed into tracheobronchial tree
- highly resistant to complete removal, high tendency of recurrence
- some juvenile papillomas resolve spontaneously at puberty
- may undergo malignant transformation to squamous cell carcinoma

Investigations
- flexible nasolaryngoscopy shows wart-like lesions with vascular core in supraglottic larynx and trachea
- bronchoscopy with biopsy to confirm diagnosis and rule out malignancy
- chest x-ray followed by CT chest if indicated. Findings of pulmonary involvement require referral to respirology
- for high-risk patients, rule out TB, HIV

Treatment
- prevention using quadrivalent HPV recombinant vaccine
- suspension microlaryngoscopy with laser removal and preservation of normal mucosa is gold standard (not curative, goal is improvement in voice and/or breathing)
  - preferably with CO_2 or KTP laser
  - other options include microdebridement and cold steel
- consider systemic adjuvants if requiring >4 surgeries/yr. These include quadrivalent HPV recombinant vaccine, bevacizumab, cidofovir, interferon, indole-3-carbinol
- PPI if concomitant GERD

Laryngeal Carcinoma

- see *Neoplasms of the Head and Neck*, OT35

Salivary Glands

Sialadenitis

Definition
- inflammation of salivary glands

Etiology
- viral most common (mumps)
- bacterial causes: *S. aureus, S. pneumoniae, H. influenzae*
- obstructive vs. non-obstructive
  - obstructive infection involves salivary stasis and retrograde bacterial flow

Predisposing Factors
- HIV
- anorexia/bulimia
- Sjögren's syndrome
- Cushing's syndrome, hypothyroidism, DM
- hepatic/renal failure
- medications that increase stasis: diuretics, tricyclic antidepressants, β-blockers, anticholinergics, antibiotics
- sialolithiasis (can cause chronic sialadenitis)

Clinical Features
- acute onset of pain and edema of parotid or submandibular gland that may lead to marked swelling
- ± fever
- ± leukocytosis
- ± suppurative drainage from punctum of the gland

Investigations
- U/S imaging to differentiate obstructive vs. non-obstructive sialadenitis

Treatment
- hydration, warm compresses, sialogogues
- cloxacillin ± abscess drainage, if bacterial

Bilateral enlargement of the parotid glands may be a manifestation of a systemic disease, such as mumps, HIV, Sjögren's, or an eating disorder (i.e. anorexia, bulimia)

Mumps usually presents with bilateral parotid enlargement ± SNHL ± orchitis

Treatment of Sialadenitis (MASH) Mnemonic

Massage
Analgesics/Antibiotics
Sialagogues
Heat/Hydration

Sialolithiasis

Definition
- ductal stone (mainly hydroxyapatite in adults, sand/sludge in children), leading to chronic sialadenitis
- 80% in submandibular gland, <20% in parotid gland, ~1% in sublingual gland

Risk Factors
- any condition causing duct stenosis or a change in salivary secretions (e.g. dehydration, diabetes, EtOH, hypercalcemia, psychiatric medications)

Clinical Features
- pain and tenderness over involved gland
- intermittent swelling related to meals
- digital palpation reveals presence of calculus

Investigations
- U/S first, and if stone identified, CT for localization; may consider sialogram

Treatment
- may resolve spontaneously
- encourage salivation to clear calculus
- massage, analgesia, antibiotics, sialogogues (e.g. lemon wedges, sour lemon candies), warm compresses
- remove calculi endoscopically, by dilating duct or orifice, or by excision through floor of the mouth
- gland-preserving surgery has long-term symptom improvement and favourable gland retention rates

Salivary Gland Neoplasms

Etiology
- anatomic distribution
  - parotid gland: 70-85%
  - submandibular gland: 8-15%
  - sublingual gland: 1%
  - minor salivary glands, most concentrated in hard palate: 5-8%
- malignant (see Table 16, OT36 and Table 17, OT37)
- benign
  - benign mixed (pleomorphic adenoma): 80%
  - Warthin's tumour (5-10% bilateral, M>F): 10%
  - cysts, lymph nodes, and adenomas: 10%
  - oncocytoma: <1%

Epidemiology
- 3-6% of all H&N neoplasms in adults
- mean age at presentation: 55-65
- M=F

Parotid Gland Neoplasms

Clinical Features
- 80% benign (most common: pleomorphic adenoma), 20% malignant (most common: mucoepidermoid)
- if bilateral, suggests benign process (e.g. Warthin's tumour, Sjögren's, bulimia, mumps) or possible lymphoma
- facial nerve involvement (e.g. facial paralysis) increases risk of malignancy

Investigations
- FNA biopsy
- CT, U/S, or MRI to determine extent of tumour

Treatment
- treatment of choice is surgery for all salivary gland neoplasms – benign and malignant
- pleomorphic adenomas are excised due to risk of malignant transformation (5% risk over prolonged period of time)
- superficial tumour
  - superficial parotidectomy above plane of CN VII ± radiation
  - incisional biopsy contraindicated
- deep lesion
  - near-total parotidectomy sparing as much of CN VII as possible
  - if CN VII involved, then it is removed and cable grafted
- complications of parotid surgery
  - hematoma, infection, salivary fistula, temporary or permanent facial paresis, Frey's syndrome (gustatory sweating), sialocele, numbness of the overlying skin
- postoperative radiotherapy, if high risk of locoregional recurrence
- chemotherapy is largely reserved for palliative cases

Prognosis
- benign: excellent, <5% of pleomorphic adenomas recur
- malignant: dependent on stage and type of malignancy (see Table 17, OT37)

A mass sitting above an imaginary line drawn between the mastoid process and angle of the mandible is a parotid neoplasm until proven otherwise

DDx Parotid Tumour

Benign
- Pleomorphic adenoma
- Warthin's tumour (more common in men)
- Benign lymphoepithelial cysts (viral etiology e.g. HIV)
- Oncocytoma

Malignant
- Mucoepidermoid carcinoma
- Adenoid cystic carcinoma
- Acinic cell carcinoma

Frey's syndrome is a postoperative complication characterized by gustatory sweating. It is thought that damaged parasympathetic nerve fibres of the auriculotemporal nerve regenerates abnormally to innervate the cutaneous sweat glands

Neck Masses

Approach to a Neck Mass

- ensure that the neck mass is not a normal neck structure (e.g. hyoid, transverse process of C1 vertebra, prominent carotid bulb)
- any neck mass persisting for >2 wk should be investigated for possible neoplastic causes

Table 15. Prevalence of Acquired Causes of Neck Lumps According to Age

Age (yr)	Possible Causes of Neck Lump		
<40	1. Inflammatory	2. Congenital/Developmental	3. Neoplastic
>40	1. Neoplastic	2. Inflammatory	3. Congenital

Differential Diagnosis
- congenital
  - lateral (branchial cleft cyst, laryngocele, plunging ranula, lymphatic/venous/venolymphatic malformation)
  - midline (thyroglossal duct cyst, dermoid cyst, teratoma, thyroid/thymus anomaly, vascular malformation)
- infectious/inflammatory
  - reactive lymphadenopathy (2° to tonsillitis, pharyngitis)
  - infectious mononucleosis
  - Kawasaki, Kikuchi-Fujimoto, Kimura, Cat-scratch, Castleman, Rosai-Dorfman disease
  - HIV
  - sialolithiasis, sialadenitis
  - thyroiditis
- granulomatous disease
  - mycobacterial infections
  - sarcoidosis
- neoplastic
  - lymphoma
  - salivary gland tumours
  - thyroid tumours
  - metastatic malignancy ("unknown primary")
  - lipoma, fibroma, hemangioma, nerve or nerve sheath tumour

Evaluation

Investigations
- history and physical (including nasopharynx and larynx)
- all other investigations and imaging are dependent upon clinical suspicion following history and physical
  - congenital: CT with contrast, excisional biopsy
  - inflammatory/infectious: WBC (infection vs. lymphoma), trial of antibiotics, chest radiograph, Mantoux TB test, CT with contrast, FNA
  - neoplasms: thyroid function tests and scans, CT with contrast, FNA (histologic examination), panendoscopy (identification of possible primary tumour)
    - panendoscopy: nasopharyngoscopy, laryngoscopy, esophagoscopy, bronchoscopy with washings, and biopsy of suspicious lesions
    - primary identified 95% of time ➔ stage and treat
    - primary occult identified 5% of time: excisional biopsy of node for histologic diagnosis ➔ manage with radiotherapy and/or neck dissection (SCC)

Inflammatory vs. Malignant Neck Masses

	Inflammatory	Neoplastic
History		
Painful	Y	
H&N infection	Y	N
Fever	Y	N
Weight loss	N	Y
CA risk factors	N	Y
Age	Younger	Older
Physical		
Tender	Y	N
Rubbery	Y	Occipital
Rock hard	N	Y
Mobile	Y	± fixed

Congenital Neck Masses

Branchial Cleft Cysts/Sinuses/Fistulae

Embryology
- at 4th wk of embryonic development, there are 4 pairs of branchial arches and 2 rudimentary arches, which are separated internally by pouches and externally by clefts
- branchial anomalies form when pouches and clefts persist and fall into 3 types:
  1. branchial fistula: persistent communication between skin and GI tract
  2. branchial sinus: blind-ended tract opening to skin
  3. branchial cyst: persistent cervical sinus with no external opening

Clinical Features
- 2nd branchial cleft malformations most common
  - sinuses and fistulae present in infancy as a small opening anterior to the SCM muscle
  - cysts present as a smooth, painless, slowly enlarging lateral neck mass, often following a URTI
- 1st branchial cleft malformations present as sinus/fistula or cyst in preauricular area (Work I) or on face over angle of mandible (Work II)
- 3rd branchial cleft malformations present as recurrent thyroiditis or thyroid abscess and have a tract which usually leads to the left pyriform sinus. Air on CT scan in or near the thyroid gland is pathognomonic for this anomaly
- there is controversy whether 4th branchial cleft anomalies exist, as they may be remnants of the thyrothymic axis

Treatment
- surgical removal of cyst or fistula tract
- if infected: allow infection to settle before removal (antibiotics may be required)

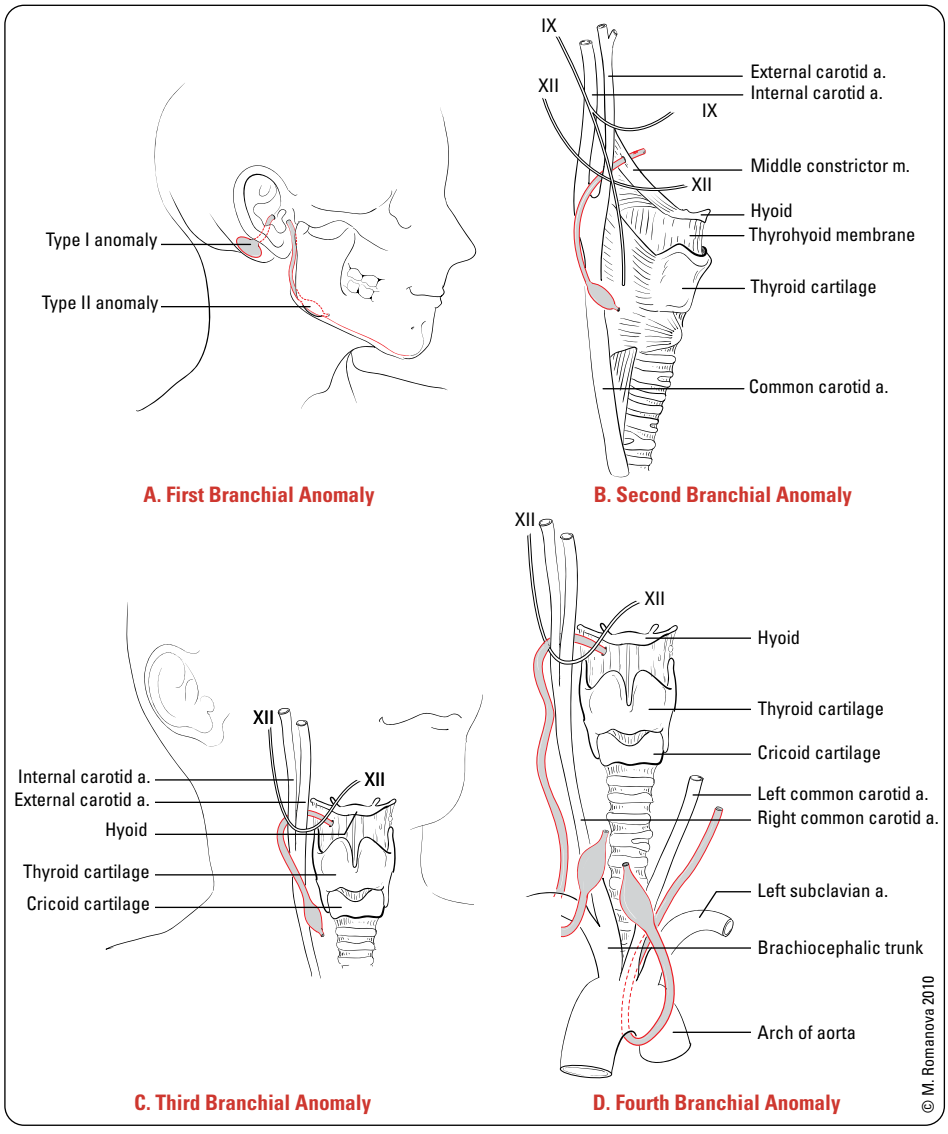

Figure 19. Branchial cleft anomalies

Thyroglossal Duct Cysts

Embryology

- thyroid originates as ventral midline diverticulum at base of tongue, caudal to junction of 3rd and 4th branchial arches (foramen cecum), and migrates down to inferior aspect of neck
- thyroglossal duct cysts are vestigial remnants of this tract

Clinical Features

- most common congenital cervical anomaly
- usually presents in childhood or from ages 20-40 as a midline cyst that enlarges with URTI and elevates with swallowing and tongue protrusion
- location can be suprahyoid or infrahyoid

Thyroglossal duct cysts are the most common congenital neck mass found in children

Treatment

- preoperative antibiotics to reduce inflammation (infection before surgery is a well-described cause of recurrence)
- small potential for neoplastic transformation, so complete excision of cyst and tissue around tract up to foramen cecum at base of tongue, with removal of central portion of hyoid bone (Sistrunk procedure) recommended

Lymphatic, Venous, or Mixed Venolymphatic Malformations

Definition
- lymphatic malformation arising from vestigial lymph channels of neck

Clinical Features
- commonly identified in many fetuses, but regress before birth and never cause a clinical problem
- usually present by age 2
- can be macrocystic (composed of large, thin-walled cysts, usually below level of mylohyoid muscle) or microcystic (composed of minute cysts, usually above level of mylohyoid muscle)
- usually painless, soft, compressible
- infection or trauma causes a sudden increase in size

Treatment
- can regress spontaneously after bacterial infection, therefore do not plan surgical intervention until several mo after infection
- macrocystic lesions can be treated by surgical excision or sclerotherapy
- microcystic lesions are difficult to treat, but can be debulked if it will not cause loss of function of normal structures, or injected with sclerotherapy in surrounding tissues
- in sclerotherapy, bleomycin is used for intraoral microcystic malformations but is less effective and requires multiple injections
- doxycycline is used for macrocystic malformations in the neck not abutting the trachea; it is more effective and requires fewer injections

Neoplasms of the Head and Neck

Pre-Malignant Disease
- lichen planus
  - lacy white lines of oral mucosa +/- erythema
  - exact cause unknown, thought to be immune-mediated
  - risk of malignant transformation 5-10%
- leukoplakia
  - white keratotic plaque/patch of oral mucosa that cannot be rubbed off
  - risk of malignant transformation 5-20%
- erythroplakia
  - red mucosal plaque adjacent to normal mucosa
  - commonly associated with epithelial dysplasia
  - associated with carcinoma *in situ* or invasive tumour in 40% of cases
- dysplasia (a feature of pre-malignant lesions)
  - histopathologic presence of mitoses and prominent nucleoli
  - involvement of entire mucosal thickness = carcinoma *in situ*
  - associated progression to invasive cancer 15-30%

Investigations
- initial metastatic screen includes chest x-ray
- scans of liver, brain, and bone only if clinically indicated
- CT scan superior to MRI for the detection of pathologic nodal disease and bone cortex invasion
- MRI superior for discriminating tumour from mucus and to detect bone marrow invasion
- ± PET scans
- endoscopy with biopsy

Treatment
- treatment depends on:
  - histologic grade of tumour, stage
  - physical and psychological health of patient
  - facilities available, expertise and experience of the medical and surgical oncology team
- in general:
  - 1° surgery for malignant oral cavity tumours with radiotherapy reserved for salvage or poor prognostic indicators
  - 1° radiotherapy for nasopharynx, oropharynx, hypopharynx, and larynx malignancies with surgery reserved for salvage, although laser endoscopic surgery for early stage larynx cancer is an option and 1° surgery for advanced (T4) pharyngeal and laryngeal cancer is the standard of care
  - there is a growing interesting in studying 1° surgery (transoral surgery (TOS)) for OPC
  - palliative chemotherapy for metastatic or incurable disease
  - concomitant chemotherapy increases survival in advanced disease
  - chemotherapy has a role as induction therapy prior to surgery and radiation
  - panendoscopy (bronchoscopy, esophagoscopy, laryngoscopy and pharyngoscopy) to detect 1° disease when lymph node metastasis is identified
  - anti-epidermal growth factor receptor treatment (cetuximab, panitumumab) has a role as concurrent therapy with radiation for SCC of the H&N (for advanced local and regional disease)

All patients presenting with a H&N mass should be asked if they are experiencing the following obstructive, referred, or local symptoms
- Oropharyngeal: Odynophagia, dysphagia, non-healing oral ulcers
- Otologic: Otalgia, HL
- Laryngeal: Dyspnea or stridor (positional vs. non-positional), hoarseness, dysphonia → positional vs. non-positional
- Nasopharyngeal: Recurrent epistaxis, unilateral nasal obstruction, persistent rhinorrhea or sinusitis
- Hemoptysis, hematemesis

Detection of cervical lymph nodes on physical exam
- False negative rate: 15-30%
- False positive rate: 30-40%

Pathological lymphadenopathy defined radiographically as
- A jugulodigastric node >1.5 cm in diameter, or a retropharyngeal node >1 cm in diameter
- A node of any size which contains central necrosis

Common sites of distant metastases for H&N neoplasms
(most common to least common) lungs > liver > bones

Risk Factors for H&N Cancer
- Smoking
- EtOH (synergistic with smoking)
- Radiation
- Occupational/environmental exposures
- Oral HPV infection (independent of smoking and EtOH exposure)
- Family history of cancer
- Previous cancer

The smaller the salivary gland, the greater the likelihood that a mass in the gland is malignant

Prognosis

- synchronous tumours occur in 0.8-18% of patients
- late development of 2nd primary is most common cause of post-treatment failure after 36 mo

Table 16. Quick Look-Up Summary of H&N Malignancies – Etiology and Epidemiology

Etiology	Epidemiology	Risk Factors
Oral Cavity		
95% SCC Others: sarcoma, melanoma, minor salivary gland tumour	Mean age: 50-60 yr M>F Most common site of H&N cancers 50% on anterior 2/3 of tongue	Smoking/EtOH Poor oral hygiene Leukoplakia, erythroplakia Lichen planus, chronic inflammation Sun exposure – lip HPV infection Plummer-Vinson syndrome Genetic/Ethnic
Nose and Paranasal Sinus		
75-80% SCC Adenocarcinoma (2nd most common) and mucoepidermoid 99% in maxillary/ethmoid sinus 10% of nose and paranasal sinus tumours arise from minor salivary glands	Mean age: 50-70 yr Rare tumours ↓ incidence in last 5-10 yr	Wood/shoe/textile industry Hardwood dust (nasal/ethmoid sinus) Nickel, chromium (maxillary sinus) Air pollution Chronic rhinosinusitis
Carcinoma of the Pharynx – Subtypes (Nasopharynx, Oropharynx, Hypopharynx, and Larynx)		
Nasopharynx		
90% SCC ~10% lymphoma	Mean age: 50-59 yr M:F=2.4:1 Incidence 0.8 per 100000 100x increased incidence in Southern Chinese	EBV Salted fish Nickel exposure Poor oral hygiene Genetic – Southern Chinese
Oropharynx		
95% SCC – poorly differentiated Up to 70% of OPC attributable to HPV	Mean age: 50-70 yr HPV+ patients with OPC are approximately 10 yr younger Prevalence of HPV+ OPC has increased by 225% from 1988 to 2004 M:F=4:1	Smoking/EtOH HPV 16 infection: increased sexual encounters, specifically oral sex
Hypopharynx		
95% SCC 3 sites 1. pyriform sinus (60%) 2. postcricoid (30%) 3. posterior pharyngeal wall (10%)	Mean age: 50-70 yr M>F 8-10% of all H&N cancer	Smoking/EtOH
Larynx		
SCC most common 3 sites 1. supraglottic (30-35%) 2. glottic (60-65%) 3. subglottic (1%)	Mean age: 45-75 yr M:F=10:1 45% of all H&N cancer	Smoking/EtOH
Salivary Gland		
40% mucoepidermoid 30% adenoid cystic 5% acinic cell 5% malignant mixed 5% lymphoma	Mean age: 55-65 yr M=F 3-6% of all H&N cancer Percentage of malignant tumours in each gland: Parotid 15-25% Submandibular 37-43% Minor salivary >80%	Radiation exposure
Thyroid (90% benign – 10% malignant)		
>80% papillary 5-15% follicular 5% medullary <5% anaplastic 1-5% Hürthle cell 1-2% metastatic	Children Adults <30 or >60 yr Nodules more common in females Malignancy more common in males	Radiation exposure Family history – papillary CA or multiple endocrine neoplasia (MEN II) Older age Male Papillary – Gardner's syndrome, Cowden syndrome, FAP

HPV and Survival of Patients with OPC
NEJM 2010;363(1):24-35
Methods: Retrospective analysis of patients with stage III or IV oropharyngeal SCC enrolled in a RCT comparing accelerated or standard fractionation radiotherapy, each combined with cisplatin therapy.
Results: Similar 3 yr overall survival rates in both treatment arms. Patients with HPV-positive tumour had better rates of overall survival at 3 yr (82.4% vs. 57.1%) and a 58% reduction in risk of death (Hazard Ratio: 0.42, 95% CI 0.27-0.66) after adjusting for age, race, tumour and nodal stage, tobacco exposure, and treatment.
Summary: The tumour HPV status of patients with oropharyngeal SCC is a strong and independent prognostic factor for survival.

Summary of Treatment for Head and Neck Masses
Stage I/II: single modality
Stage III/IV: dual modality

Table 17. Quick Look-Up Summary of H&N Malignancies – Diagnosis and Treatment

Clinical Features	Investigations	Treatment	Prognosis
Oral Cavity			
Asymptomatic neck mass (30%) Non-healing ulcer ± bleeding Dysphagia, sialorrhea, dysphonia Oral fetor, otalgia, leukoplakia, or erythroplakia (pre-malignant changes or clinically isolated syndrome)	Biopsy CT	1º surgery local resection ± neck dissection ± reconstruction 2º radiation	5 yr overall survival T1/T2: 75% T3/T4: 30-35% Poor prognostic indicators Depth of invasion, close surgical margins location (tongue worse than floor of mouth) Cervical nodes
Nose and Paranasal Sinus			
Early Symptoms Unilateral nasal obstruction Epistaxis, rhinorrhea	CT/MRI Biopsy	Surgery and radiation Chemoradiotherapy	5 yr survival: 30-60% Poor prognosis 2o to late presentation
Late Symptoms 2º to invasion of nose, orbit, nerves, oral cavity, skin, skull base, cribriform plate			
Nasopharynx			
Cervical nodes (60-90%) Nasal obstruction, epistaxis Unilateral otitis media ± HL CN III to VI, IX to XII (25%) Proptosis, voice change, dysphagia	Nasopharyngoscopy Biopsy CT/MRI	1º radiation ± chemoradiation Surgery for limited or recurrent disease	5 yr survival T1: 79% T2: 72% T3: 50-60% T4: 36-42%
Oropharynx			
Odynophagia, otalgia Ulcerated/enlarged tonsil Fixed tongue/trismus/dysarthria Oral fetor, bloody sputum HPV+ OPC predominantly arises at base of tongue or tonsillar region Cervical lymphadenopathy (60%) Distant mets: lung/bone/liver (7%)	Biopsy Determine HPV status via RT-PCR: positive if presence of HPV DNA and p16 overexpression CT	1º radiation, consider therapy de-intensification for HPV+ patients 2º surgery local resection ±neck dissection ±reconstruction 1º surgery emerging role of Transoral Robotic Surgery	5 yr overall survival Stratified by TNM stage (I, II, III, IV) HPV negative OPC (70%, 58%, 50%, 30%) HPV positive OPC (92%, 87%, 74%, 40%) HPV positive OPC further stratified by stage, age, and smoking pack years (PY) group I (T1-3N0-N2c, ≤20 PY): 89% group II (T1-3N0-N2c, >20 PY): 64% group III (T4 or N3, age ≤70): 57% group IVA (T4 or N3, age >70): 40%
Hypopharynx			
Dysphagia, odynophagia Otalgia, hoarseness Cervical lymphadenopathy	Pharyngoscopy Biopsy CT	1º radiation 2º surgery	5 yr survival T1: 53% T2/T3: 36-39% T4: 24%
Larynx			
Dysphagia, odynophagia, globus Otalgia, hoarseness Dyspnea/stridor Cough/hemoptysis Cervical nodes (rare with glottic CA)	Laryngoscopy Biopsy CT/MRI	Early stage: single modality (radiation or surgery) Late stage: multimodality (surgery, radiotherapy, chemotherapy)	5 yr survival T4: >40% (surgery with radiation) Control rate early lesions: >90% (radiation) 10 to 12% of small lesions fail radiotherapy
Salivary Gland			
Painless mass (occ. pain is possible) CN VII palsy Cervical lymphadenopathy Rapid growth Invasion of skin Constitutional signs/symptoms	FNA MRI/CT/U/S	1º surgery ± neck dissection Postoperative radiotherapy Chemotherapy if unresectable	Parotid 10 yr survival: 85, 69, 43, and 14% for stages T1 to T4 Submandibular 2 yr survival: 82%, 5 yr: 69% Minor salivary gland 10 yr survival: 83, 52, 25, 23% for stages T1 to T4
Thyroid			
Thyroid mass, cervical nodes Vocal cord paralysis, hoarseness Hyper/hypothyroidism Dysphagia	FNA U/S	1º surgery I^{131} for intermediate and high-risk well-differentiated thyroid cancer	Recurrences occur within 5 yr Need long-term follow-up: clinical exam, thyroglobulin
Parathyroid			
Symptoms of hypercalcemia Neck mass Bone disease, renal disease Pancreatitis	Sestamibi	Wide surgical excision Postoperative monitoring of serum Ca^{2+}	Recurrence rates 1 yr: 27% 5 yr: 82% 10 yr: 91% Mean survival: 6-7 yr

CT imaging for Head and Neck Malignancies are done with contrast for the neck and chest. CT head is not routinely order.

Thyroid Carcinoma

Table 18. Bethesda Classification of Thyroid Cytology

Diagnostic Category	Risk of Malignancy
Non-diagnostic or unsatisfactory	1-4%
Benign	0-3%
Follicular lesion of undetermined significance or atypia of undetermined significance	5-15%
Follicular neoplasm or suspicious for a follicular neoplasm	15-30%
Suspicious for malignancy	60-75%
Malignant	97-99%

The Bethesda System for Reporting Thyroid Cytopathology (TBSRTC) is a reporting system for thyroid FNA.

Table 19. Thyroid Carcinoma

	Papillary	Follicular	Medullary	Anaplastic	Lymphoma
Incidence (% of all thyroid cancers)	90-92%	4-6%		<1%	<1% Most common is Diffuse Large B Cell Lymphoma (DLBCL)
Route of Spread	Lymphatic	Hematogenous		N/A	
Histology	Orphan Annie nuclei Psammoma bodies Papillary architecture	Capsular/vascular invasion influences prognosis	Amyloid May secrete calcitonin, prostaglandins, ACTH, serotonin, kallikrein, or bradykinin	Giant cells Spindle cells	
Other	**P**s – **P**apillary cancer **P**opular (most common) **P**alpable lymph nodes **P**ositive I^{131} uptake **P**ositive prognosis **P**ostoperative I^{131} scan to guide treatments	**F**s – **F**ollicular cancer **F**ar away mets **F**emale (3:1) NOT FNA (cannot be diagnosed by FNA) **F**avourable prognosis	**M**s – **M**edullary cancer **M**ultiple endocrine neoplasia (**M**EN IIa or IIb) a**M**yloid **M**edian node dissection	More common in elderly 70% in women 20-30% have Hx of differentiated thyroid CA (mostly papillary) or nodular goitre mass Rapidly enlarging neck Rule out lymphoma	Usually non-Hodgkin's lymphoma Rapidly enlarging thyroid mass Hx of Hashimoto's thyroiditis increases risk 60x 4:1 female predominance dysphagia, dyspnea, stridor, hoarseness, neck pain, facial edema, accompanied by "B" symptoms*
Prognosis	98% at 10 yr	92% at 10 yr			5 yr survival Stage IE: 55%-80% Stage IIE: 20%-50% Stage IIE/IV: 15%-35%
Treatment	Early stage: Lobectomy (<1cm) or Total or near total thyroidectomy (≥1 cm) Late stage: Total thyroidectomy ± neck dissection ± postoperative I^{131} treatment	Early stage: Total or near total thyroidectomy Late stage: Total thyroidectomy ± neck dissection ± postoperative I^{131} treatment	Total thyroidectomy Median and/or lateral compartment node neck dissection (based on serum calcitonin) Modified neck dissection Postoperative thyroxine, radiotherapy Tracheostomy Screen relatives Targeted therapy for metastatic palliative cases	Tracheostomy Local tumour: total thyroidectomy Radiotherapy Chemotherapy and targeted therapy Palliative Care	Non-surgical Combined radiation Chemotherapy (CHOP**)

*B symptoms = fever, night sweats, chills, weight loss >10% in 6 mo
** CHOP = cyclophosphamide, adriamycin, vincristine, prednisone

Approach to Thyroid Nodule

- all patients with thyroid nodules require evaluation of serum TSH and ultrasound of the thyroid gland, central and lateral neck
- intermediate to high suspicion nodule >1 cm and low suspicion nodule >1.5 cm should undergo FNA
- nodules <1 cm with clinical symptoms or lymphadenopathy may require further evaluation
- when performing repeat FNA on initially non-diagnostic nodules, U/S-guided FNA should be employed
- nuclear scanning has minimal value in the investigation of the thyroid nodule
- molecular testing is increasingly used to identify gene mutations associated with thyroid cancers to determine "high-risk" from "low-risk" thyroid nodules

Table 20. Management of the Thyroid Nodule

Treatment	Indications
Radioiodine therapy	Treatment of hyperthyroidism After surgery as adjuvant treatment of intermediate-high-risk papillary or follicular carcinoma
Chemotherapy and targeted therapy (tyrosine kinase inhibitors)	Recurrent/residual medullary CA, anaplastic CA, or thyroid lymphoma
Surgical excision	Nodule that is suspicious on FNA cytology Malignancy other than anaplastic CA, or thyroid lymphoma Mass that is benign on FNA but increasing in size on serial imaging and/or >3-4 cm in size Hyperthyroidism not amenable to medical therapy

Indications for Postoperative Radioactive Iodine Ablation – I^{131}
- Adjuvant therapy: decrease recurrent disease
- Radioactive Iodine (RAI) therapy: treat persistent cancer

Paediatric Otolaryngology

Acute Otitis Media

Definition
- both presence of MEE/MEI and acute onset of MEE/MEI symptoms

Epidemiology
- most frequent diagnosis in sick children visiting clinicians' offices and most common reason for antibiotic administration
- peak incidence between 6-15 mo: ~85% of children have >1 episode by 3 years old
- seasonal variability: peaks in winter

Etiology
- primary defect causing AOM: Eustachian tube dysfunction/obstruction ➔ stasis/colonization by pathogens
- bacterial: S. pneumoniae, non-typeable *H. influenzae, M. catarrhalis*, group A *Streptococcus*, *S. aureus*
- viral: RSV, influenza, parainfluenza, adenovirus
- commonly due to bacterial/viral co-infection

Predisposing Factors
- Eustachian tube dysfunction/obstruction
  - swelling of tubal mucosa
    - URTI
    - allergic rhinitis
    - chronic rhinosinusitis
  - obstruction/infiltration of Eustachian tube ostium
    - tumour: nasopharyngeal carcinoma (adults)
    - adenoid hypertrophy (by maintaining a source of infection rather than obstruction)
    - barotrauma (sudden changes in air pressure)
  - inadequate tensor palati function: cleft palate (even after repair)
  - abnormal Eustachian tube
    - Down syndrome (horizontal position of Eustachian tube), Crouzon syndrome, cleft palate, and Apert syndrome
- aberrant function of:
  - cilia of Eustachian tube: Kartagener's syndrome
  - mucus secreting cells
  - capillary network that provides humoral factors, PMNs, phagocytic cells
- immunosuppression/deficiency due to chemotherapy, steroids, DM, hypogammaglobulinemia, cystic fibrosis

Risk Factors
- non-modifiable: young age, family history of OM, prematurity, orofacial abnormalities, immunodeficiencies, Down syndrome, race, and ethnicity
- modifiable: lack of breastfeeding, daycare attendance, household crowding, exposure to cigarette smoke or air pollution, pacifier use

Pathogenesis
- obstruction of Eustachian tube ➔ air absorbed in middle ear ➔ negative pressure (an irritant to middle ear mucosa) ➔ edema of mucosa with exudate/effusion ➔ infection of exudate from nasopharyngeal secretions

Clinical Features
- triad of otalgia, fever (especially in younger children), and CHL
- rarely tinnitus, vertigo, and/or facial nerve paralysis
- otorrhea if TM perforated
- infants/toddlers
  - ear-tugging (this alone is not a good indicator of pathology)
  - HL, balance disturbances (rare)
  - irritable, poor sleeping
  - vomiting and diarrhea
  - anorexia
- otoscopy of TM
  - hyperemia
  - bulging, pus may be seen behind TM
  - loss of landmarks: handle and long process of malleus not visible

Diagnosis
- history
  - acute onset of otalgia or ear tugging in a preverbal child, otorrhea, decreased hearing
  - unexplained irritability, fever, upper respiratory symptoms, poor sleeping, anorexia, N/V, and diarrhea
- physical
  - febrile
  - MEE on otoscopy: immobile TM, acute otorrhea, loss of bony landmarks, opacification of TM, air-fluid level behind TM
  - MEI on otoscopy: bulging TM with marked discolouration (hemorrhagic, red, grey, or yellow)

Management
- supportive care and symptom management: maintain hydration, analgesic, and antipyretic (acetaminophen, ibuprofen)
- watchful waiting: in a generally healthy child >6 mo of age with unilateral, non-severe, suspected AOM
  - without MEE or with MEE but non-bulging or mildly erythematous TM
- consider viral etiology
- reassess in 24-48 h if not clinically improved (or earlier if worsening)
  - mildly ill (alert, responsive, no rigors, mild otalgia, fever <39°C, <48 h illness) with MEE present AND bulging TM
- observe and follow-up in 24-48 h – if not improved or worsening, treat with antimicrobials
- antimicrobial indications: infants <6 mo of age or in a generally healthy child >6 mo of age with suspected AOM and the following features
  - moderately or severely ill (irritable, difficulty sleeping, poor antipyretic response, severe otalgia) OR fever ≥39°C OR >48 h of symptoms
  - perforated TM with purulent drainage
- referral to otolaryngology for myringotomy and tympanostomy tubes may be warranted for recurrent infections

Treatment
- antimicrobial agents for AOM
  - 5 d course of appropriate dose antimicrobial recommended for most ≥2 y/o with uncomplicated AOM. 10 d course for 6-24 mo, perforated TM, or recurrent AOM
  - 1st line treatment (no penicillin allergy)
    - high-dose amoxicillin: 80-90 mg/kg/d divided 2 x/d
  - 2nd line treatment
    - azithromycin: 10 mg/kg (1st line for penicillin allergy)
    - clarithromycin: 15 mg/kg/d divided 2 x/d (1st line for penicillin allergy)
    - cefprozil: 30 mg/kg/d divided 2 x/d
    - cefuroxime axetil: 30 mg/kg/d divided 2-3 x/d
    - ceftriaxone: 50 mg/kg IM (or IV) x 3 doses
  - if initial therapy fails (i.e. no symptomatic improvement after 2-3 d)
    - high-dose amoxicillin-clavulanate: 45-60 mg/kg/d (7:1 formulation, 400 mg/5 mL suspension) for 10 d for child weighing ≤35 kg, or 500 mg tablets TID for 10 d for child weighing >35 kg
    - myringotomy and tympanostomy, if ≥4 AOM episodes (with middle ear effusion) within 12 mo

Clinical Assessment of AOM in Paediatrics
JAMA 2010;304:2161-69
In assessment of AOM in paediatrics, ear pain is the most useful symptom with an LR between 3.0-7.3. Useful otoscopic signs include erythematous (LR 8.4, 95% CI 7-11), cloudy (LR 34, 95% CI 28-42), bulging (LR 51, 95% CI 36-73), and immobile tympanic membrane (LR 31, 95% CI 26-37) on pneumatic otoscopy.

Antibiotics for AOM in Children
Cochrane DB Syst Rev 2013;1:CD000219
Study: Meta-analysis of Randomized Controlled Trials (RCTs) on children (1-15 mo) with acute otitis media comparing any antibiotic regime to placebo and expectant observation.
Data Sources: Cochrane Central Register of Controlled Trials (2012 issue 10), MEDLINE (1966 to October 2012), OLDMEDLINE (1958 to 1965), EMBASE (January 1990 to November 2012), Current Contents (1966 to November 2012), CINAHL (2008 to November 2012) and LILACS (2008 to November 2012) without language restrictions.
Main Outcomes: 1) Pain at 24 h, 2-3 d, and 4-7 d; 2) Abnormal tympanometry findings; 3) TM perforation; 4) Contralateral otitis; 5) AOM recurrences; 6) Serious complications from AOM; 7) Adverse effects from antibiotics.
Results: Treatment with antibiotics had no significant impact on pain at 24 h. However, pain at 2-3 d and 4-7 d was lower in the antibiotic groups with a NNT of 20. Antibiotics had no significant effect on tympanometry findings, number of AOM recurrences, or severity of complications. Antibiotic treatment led to a significant reduction in TM perforations (NNT 33) and halved contralateral AOM (NNT 11). Adverse events (vomiting, diarrhea, or rash) occurred more often in children taking antibiotics.
Conclusion: The role of antibiotics is largely restricted to pain control at 2-7 d, but most (82%) settle without antibiotics. This can also be achieved by analgesics. However, antibiotic treatment can reduce risk of TM perforation and contralateral AOM episodes. These benefits must be weighed against risks of adverse events from antibiotics.

Complications
- extracranial
  - HL and speech delay (secondary to persistent MEE), TM perforation, extension of suppurative process to adjacent structures (mastoiditis, petrositis, labyrinthitis), cholesteatoma, facial nerve palsy, middle ear atelectasis, ossicular necrosis, vestibular dysfunction
- intracranial
  - meningitis, epidural/brain abscess, subdural empyema, lateral and cavernous sinus thrombosis, sigmoid sinus thrombophlebitis, carotid artery thrombosis, facial nerve paralysis
- other
  - postauricular abscess, Bezold's abscess

Otitis Media with Effusion

Definition
- presence of fluid in the middle ear without signs or symptoms of ear infection

Epidemiology
- most common cause of paediatric HL
- not exclusively a paediatric disease
- frequently follows AOM in children
- MEE have been shown to persist following an episode of AOM for 1 mo in 40% of children, 2 mo in 20%, and >3 mo in 10% (i.e. 90% of children clear the fluid within 3 mo – observe for 3 mo before considering myringotomy and tubes)

Risk Factors
- same as AOM

Clinical Features
- CHL ± tinnitus
  - confirm with audiogram and tympanogram (flat) (see Figure 16B, OT10 and Figure 17B, OT11)
- fullness – blocked ear
- ± pain, low grade fever
- otoscopy of tympanic membrane
  - discolouration – amber or dull grey with "glue" ear
  - meniscus fluid level behind TM
  - air bubbles
  - retraction pockets/TM atelectasis
  - most reliable finding with pneumatic otoscopy is immobility

Treatment
- expectant: 90% resolve by 3 mo
  - watchful waiting for 3 mo from onset, or 3 mo from diagnosis if onset unknown
- document HL with audiogram
- recommend **against** intranasal or systemic steroids, systemic antibiotics, antihistamines, decongestants for OME treatment
- surgery: myringotomy ± ventilation tubes to equalize pressure and drain ear (tympanostomy tubes recommended) ± adenoidectomy (not recommended in <4 y/o unless nasal obstruction, chronic adenoiditis; recommended in ≥4 y/o)

Complications of OME
- HL, speech delay, learning problems in young children
- chronic mastoiditis
- ossicular erosion
- cholesteatoma, especially when retraction pockets involve pars flaccida
- retraction of tympanic membrane, atelectasis, ossicular fixation

Indications for Myringotomy and Tympanostomy Tubes in Recurrent AOM and OME*
- Chronic bilateral OME and documented hearing difficulties >3 mo
- Unilateral or bilateral OME >3 mo and symptoms likely attributable to OME (e.g. balance problems, poor school performance, ear discomfort, etc.)
- At-risk children (permanent HL, speech/language delay, autism-spectrum disorder, craniofacial disorders, blindness, cleft palate, developmental delay) with unilateral or bilateral OME with type B tympanogram or persistent effusion >3 mo
- Recurrent AOM (>3 episodes in 6 mo or >4 in 12 mo) with unilateral or bilateral MEE

*Clinical practice guidelines: Tympanostomy tubes in children. Otolaryng Head Neck 2013;149:S1-S35

Effectiveness of Tympanostomy Tubes for Otitis Media: A Meta-Analysis
Paediatrics 2017;139(6):e20170125
Study: Systematic review evaluating the effectiveness of tympanostomy tubes in children with chronic OM with effusion and recurrent AOM compared to watchful waiting.
Data Sources: MEDLINE, Cochrane Central Register of Controlled Trials, EMBASE, CINAHL.
Results: Children treated with tympanostomy tubes compared with watchful waiting had a net decrease (improvement) in mean hearing threshold of 9.1 dB at 1-3 mo and 0.0 by 12-24 mo. Children with recurrent AOM may have fewer episodes after tympanostomy tube.
Conclusions: Tympanostomy tubes improve hearing at 1-3 mo compared with watchful waiting, with no evidence of benefit by 12-24 mo. More evidence is needed for recurrent AOM. The benefits of tympanostomy tubes must be weighed against a variety of associated adverse events.

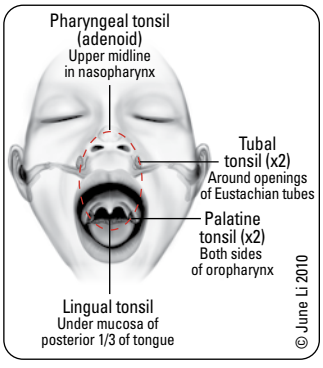

Figure 20. Waldeyer's ring
An interrupted circle of protective lymphoid tissue at the upper ends of the respiratory and alimentary tracts

Adenoid Hypertrophy

Definition
- size peaks at age 5 and resolves by age 12
- increase in size with repeated URTI and allergies

Clinical Features
- nasal obstruction
  - adenoid facies (open mouth, high arched palate, narrow midface, malocclusion)
  - history of hypernasal voice and snoring
  - long-term mouth breather; minimal air escape through nose
- choanal obstruction
  - chronic rhinosinusitis/rhinitis
  - OSA
- chronic inflammation
  - nasal discharge, post-nasal drip, and cough
  - cervical lymphadenopathy

Diagnosis
- enlarged adenoids on nasopharyngeal exam (usually with flexible nasopharyngoscope)
- enlarged adenoid shadow on lateral soft tissue x-ray (palate elevation can make adenoid look larger)

Treatment
- self-resolving due to age-related adenoid atrophy
- antibiotics, if infectious
  - uncomplicated: amoxicillin, clindamycin or azithromycin (penicillin allergies)
  - chronic or recurrent: amoxicillin-clavulanate
- adenoidectomy

Complications
- Eustachian tube obstruction leading to serous otitis media
- interference with nasal breathing, necessitating mouth breathing
- malocclusion
- sleep apnea/respiratory disturbance
- orofacial developmental abnormalities

Adenoidectomy

Indications for Adenoidectomy
- chronic upper airway obstruction with sleep disturbance/apnea ± cor pulmonale
- chronic nasopharyngitis resistant to medical treatment
- chronic serous OM and chronic suppurative OM (with 2nd set of tubes)
- recurrent AOM resistant to antibiotics
- suspicion of nasopharyngeal malignancy
- persistent rhinorrhea secondary to nasal obstruction
- persistent adenoiditis after two courses of antibiotics
- hyponasal speech
- dental malocclusion or orofacial growth disturbance documented by orthodontist or dentist

Contraindications
- uncontrollable coagulopathy
- recent pharyngeal infection
- conditions that predispose to velopharyngeal insufficiency (cleft palate, impaired palatal function, or enlarged pharynx)

Complications
- bleeding, infection
- velopharyngeal insufficiency (hypernasal voice or nasal regurgitation)
- scarring of Eustachian tube orifice

Sleep-Disordered Breathing in Children

Definition
- spectrum of sleep-related breathing abnormalities ranging from snoring to OSA

Epidemiology
- peak incidence between 2-8 yr when tonsils and adenoids are the largest relative to the pharyngeal airway

Etiology
- due to a combination of anatomic and neuromuscular factors
  - adenotonsillar hypertrophy
  - craniofacial abnormalities
  - neuromuscular hypotonia (e.g. cerebral palsy, Down syndrome)
  - obesity

Clinical Features
- nighttime symptoms: heavy snoring, pauses or apnea, sleeping with neck hyperextended, enuresis
- daytime symptoms: mouth breathing, excessive daytime sleepiness, behavioural/learning problems, symptoms of ADHD (e.g. inattention, hyperactivity), morning headache, failure to thrive

Investigations
- flexible nasopharyngoscopy for assessment of nasopharynx and adenoids
- polysomnography (apnea-hypopnea index >1/h considered abnormal)
  - children: Mild OSA ≥1 – <5/h; Moderate OSA ≥5 – <10/h; Severe OSA ≥10/h
  - adults: Mild OSA 5.1-15/h; Moderate OSA 15.1-30/h; Severe OSA >30.1/h

Treatment
- nonsurgical: CPAP, BiPAP, sleep hygiene, weight loss in overweight/obese child with OSA
- medication: topical nasal steroids and leukotriene-receptor antagonists for mild OSA or residual sleep-disordered breathing post-adenotonsillectomy
- surgical: bilateral tonsillectomy and adenoidectomy (T&A) is surgery of choice
  - if persistent OSA following tonsillectomy and adenoidectomy, consider adenoid regrowth
  - if these fail and patient not tolerant of positive airway pressure therapy, consider lingual tonsillectomy, midline posterior glossectomy, tongue suspension or other surgeries targeting areas of resistance as required; surgery may be guided by Drug-Induced Sleep Endoscopy or cineradiography-MRI to localize site of resistance

Peritonsillar Abscess (Quinsy)

Definition
- cellulitis of space behind tonsillar capsule extending onto soft palate, leading to abscess

Etiology
- bacterial: group A *Streptococcus* (GAS) (50% of cases), *S. pyogenes, S. aureus, H. influenzae*, and anaerobes

Epidemiology
- can develop from acute tonsillitis with infection spreading into plane of tonsillar bed (see Paediatrics, P64)
- unilateral
- most common in 15-30 yr age group

Clinical Features
- trismus (due to irritation and reflex spasm of the medial pterygoid) is the most reliable indicator of peritonsillar abscess
- fever and dehydration
- sore throat, dysphagia, odynophagia, and drooling
- extensive peritonsillar swelling but tonsil may appear normal
- edema of soft palate
- uvular deviation
- dysphonia (edema → failure to elevate palate) 2° to CN X involvement
- unilateral referred otalgia
- cervical lymphadenitis

Quinsy Triad
- Trismus
- Uvular deviation
- Dysphonia ("hot potato voice")

Complications
- aspiration pneumonia 2° to spontaneous rupture of abscess
- airway obstruction
- lateral dissection into parapharyngeal and/or carotid space
- bacteremia
- retropharyngeal abscess

Treatment
- secure airway
- surgical drainage (incision or needle aspiration) with C&S
- warm saline irrigation
- IV penicillin G x 10 d if cultures positive for GAS
- add PO/IV metronidazole or clindamycin x 10 d if culture positive for *Bacteroides*
- consider tonsillectomy after second episode

Other Sources of Parapharyngeal Space Infections
- pharyngitis
- acute suppurative parotitis (see *Salivary Glands*, OT31)
- AOM
- mastoiditis (Bezold's abscess)
- odontogenic infection

Tonsillectomy

Absolute Indications
- most common indication: sleep-disordered breathing
- 2nd most common indication: recurrent throat infections
- tonsillar hypertrophy causing upper airway obstruction, OSA, severe dysphagia, or cardiopulmonary complications such as cor pulmonale
- suspicion of malignancy (e.g. lymphoma, SCC)
- orofacial/dental deformity
- hemorrhagic tonsillitis

Relative Indications (To Reduce Disease Burden)
- recurrent throat infection with a frequency of at least 7 episodes in the past yr, at least 5 episodes per yr for 2 yr, or at least 3 episodes per yr for 3 yr with documentation in the medical record for each episode of sore throat, and 1 or more of the following: temperature >38.3°C, cervical adenopathy, tonsillar exudate, or positive test for group A β-hemolytic *Streptococcus* (Paradise Criteria)
- chronic tonsillitis with halitosis (bad breath) or sore throat ± tonsilloliths (clusters of material that form in the crevices of the tonsils)
- complications of tonsillitis: quinsy/peritonsillar abscess, parapharyngeal abscess, retropharyngeal abscess
- failure to thrive

Relative Contraindications
- velopharyngeal insufficiency: overt or submucous/covert cleft of palate, impaired palatal function due to neurological or neuromuscular abnormalities
- hematologic: coagulopathy, anemia
- infectious: active local infection without urgent obstructive symptoms

Complications
- hemorrhage: primary (within 24 h); secondary (within first 7-10 d)
- odynophagia and/or otalgia; dehydration 2° to odynophagia
- infection
- atlantoaxial subluxation (Grisel's syndrome) - rare

Airway Problems in Children

DIFFERENTIAL DIAGNOSIS BY AGE GROUP

Neonates (Obligate Nose Breathers)
- extralaryngeal
  - pyriform aperture stenosis
  - septal deviation
  - choanal atresia (e.g. CHARGE syndrome)
  - nasopharyngeal dermoid, glioma, encephalocoele
  - glossoptosis: Pierre-Robin sequence, Down syndrome, lymphatic malformation, hemangioma
- laryngeal
  - laryngomalacia: most common cause of stridor in children
  - saccular cyst/laryngocele
  - vocal cord palsy (due to trauma or Arnold-Chiari malformation)
  - glottic web
  - laryngeal cleft
  - laryngeal papillomatosis
  - subglottic stenosis

- tracheal
  - TEF
  - compression by vascular structure (e.g. left pulmonary artery sling, vascular ring)
  - tracheomalacia (anterior displacement of trachealis muscle)
  - complete tracheal rings

2-3 Months
- congenital
  - laryngomalacia
  - vascular: subglottic hemangioma (more common), innominate artery compression, double aortic arch
  - laryngeal papilloma
- acquired
  - subglottic stenosis: post-intubation
  - tracheal granulation: post-intubation
  - tracheomalacia: post-tracheotomy and TEF repair

Infants – Sudden Onset
- foreign body aspiration
- croup
- bacterial tracheitis
- caustic ingestion
- epiglottitis

Children and Adults
- infection
  - Ludwig's angina
  - peritonsillar/parapharyngeal abscess
  - retropharyngeal abscess
- neoplastic
  - SCC (larynx, hypopharynx (adults))
  - retropharyngeal: lymphoma, neuroblastoma
  - nasopharyngeal: carcinoma, rhabdomyosarcoma
- allergic
  - angioneurotic edema
  - polyps (suspect cystic fibrosis in children)
- trauma
  - laryngeal fracture, facial fracture
  - burns and lacerations
  - post-intubation
  - caustic ingestion
- congenital
  - lingual thyroglossal duct cyst
  - lingual tonsil hypertrophy
  - lingual thyroid

Signs of Airway Obstruction

Stridor
- note quality, timing (suggests site of stenosis)
  - inspiratory: vocal cords or above
  - biphasic: subglottis and extrathoracic trachea
  - expiratory: distal tracheobronchial tree
- body position important
  - lying prone: double aortic arch
  - lying supine: laryngomalacia, glossoptosis

Respiratory Distress
- nasal flaring
- tracheal tug
- supraclavicular and intercostal indrawing
- sternal retractions
- use of accessory muscles of respiration
- tachypnea
- cyanosis
- altered LOC

Feeding Difficulty and Aspiration
- supraglottic lesion
- laryngomalacia
- vocal cord paralysis
- laryngeal cleft → aspiration pneumonia
- TEF

Acute Laryngotracheobronchitis (Croup)

Definition
- inflammation of tissues in subglottic space ± tracheobronchial tree
- swelling of mucosal lining associated with thick, viscous, mucopurulent exudate which compromises upper airway (subglottic space is narrowest portion of upper airway)
- normal function of ciliated mucous membrane impaired

Etiology
- viral: parainfluenzae I (most common), II, III, influenza A B, RSV

Clinical Features
- age: 6 mo-3 yr
- preceded by URTI symptoms
- generally occurs at night
- biphasic stridor and croupy cough (loud, sea-lion bark)
- appear less toxic than epiglottitis
- supraglottic area normal
- rule out foreign body and subglottic stenosis
- "steeple-sign" on AP x-ray of neck
- if recurrent croup, think subglottic stenosis

Signs of Croup

The 3 Ss
Stridor
Subglottic swelling
Seal bark cough

Treatment
- racemic epinephrine via metered-dose inhaler q1-2 h PRN (if severe croup, >2 Westley Croup Score)
- systemic corticosteroids (e.g. dexamethasone 0.5 mg/kg, prednisone)
- adequate hydration
- close observation for 3-4 h
- positive pressure ventilation, nasal trumpet, laryngeal mask airway, intubation if severe (use smaller endotracheal tube than expected for age)
- hospitalize if poor response to steroids after 4 h and persistent stridor at rest
- consider alternate diagnosis if poor response to therapy (e.g. bacterial tracheitis)
- if recurrent episodes of croup-like symptoms, consider bronchoscopy for definitive diagnosis

Acute Epiglottitis

Definition
- acute inflammation causing swelling of supraglottic structures of the larynx without involvement of vocal cords

Acute epiglottitis is a medical emergency

Etiology
- *H. influenzae* type B
- relatively uncommon condition due to HiB vaccine
- common causes now include *S. pneumoniae* and *S. aureus*

When managing epiglottitis, it is important not to agitate the child, as this may precipitate complete obstruction

Clinical Features
- any age, most commonly 1-4 yr
- rapid onset
- toxic-looking, fever, anorexia, restlessness
- cyanotic/pale, inspiratory stridor, slow breathing, lungs clear with decreased air entry
- prefers sitting up ("tripod" posture), open mouth, drooling, tongue protruding, sore throat, dysphagia

Thumb sign: cherry-shaped epiglottic swelling with loss of the normal air space of the vallecula seen on lateral neck radiograph

Investigations and Management
- examining the throat may lead to potential laryngospasm and airway compromise; ensure an anesthesiologist/otolaryngologist is present and make preparations for intubation or tracheotomy prior to any manipulation
- WBC (elevated), blood, and pharyngeal cultures after intubation
- lateral neck radiograph (only done if patient stable) shows "thumb sign"

Treatment
- secure airway
- IV access with hydration
- antibiotics: IV cefuroxime, cefotaxime, or ceftriaxone (10-14 d course should be completed)
- moist air
- extubate when leak around tube occurs and afebrile
- watch for meningitis

Subglottic Stenosis

Congenital
- diameter of subglottis <4 mm in neonate (due to thickening of soft tissue of subglottic space or maldevelopment of cricoid cartilage), or smaller than average size for age as determined by Myer-Cotton grading system

Acquired
- following prolonged, repeated, or traumatic intubation
  - most commonly due to endotracheal intubation; nasal intubation is less traumatic and preferred in long-term intubation, as it puts less pressure on the subglottis (tube sits at different orientation) and there is less movement
  - subglottic stenosis is related to duration of intubation and endotracheal tube size resulting in pressure necrosis and subsequent scar formation
- can also be due to foreign body, infection (e.g. TB, diphtheria, syphilis), or chemical irritation

Clinical Features
- biphasic stridor
- respiratory distress
- recurrent/prolonged croup

Diagnosis
- rigid laryngoscopy and bronchoscopy

Treatment
- if soft stenosis: divide tissue with knife or laser, dilate with balloon ± steroids
- if firm stenosis: laryngotracheoplasty

Laryngomalacia

Definition
- short aryepiglottic folds, omega-shaped epiglottis, redundant mucosa over arytenoids
- caused by indrawing of supraglottis on inspiration, leading to breathing against closed glottis, causing laryngopharyngeal reflux of acid

Laryngomalacia is the most common cause of stridor in infants

Clinical Features
- high-pitched inspiratory stridor at 1-2 wk
- stridor is constant or intermittent and more pronounced when supine or following URTI
- usually mild, but can be associated with cyanosis or feeding difficulties when severe, leading to failure to thrive

Treatment
- observation ± proton pump inhibitor (to break the acid reflux cycle that leads to edema and worse airway obstruction) is usually sufficient, as symptoms spontaneously subside by 12-18 mo in >90% of cases
- if severe, division of the aryepiglottic folds (supraglottoplasty) provides relief

Foreign Body

Ingested
- usually stuck at cricopharyngeus muscle
- coins, toys, batteries (emergency)
- presents with drooling, dysphagia, stridor if very large

Foreign body inhalation is the most common cause of accidental death in children

Aspirated
- usually stuck at right main bronchus
- peanuts, carrot, apple core, popcorn, balloons
- presentation
  - stridor if lodged in trachea (beware of the silent child as there may be complete obstruction)
  - unilateral "asthma" if bronchial, therefore often misdiagnosed as asthma
  - if totally occludes airway: cough, lobar pneumonia, atelectasis, mediastinal shift, pneumothorax, death

Button batteries MUST be ruled out as a foreign body (vs. coins) as they are lethal and can erode through the esophagus. Batteries have a halo sign around the rim on AP x-ray and a step deformity on lateral x-ray

Diagnosis and Treatment
- sudden onset, not necessarily febrile or elevated WBC
- any patient with suspected foreign body should be kept NPO immediately
- older patient: inspiratory-expiratory chest x-ray (if patient is stable)
- younger patient: right and left decubitus chest x-rays. Lack of lung deflation while resting on dependent side suggests foreign body blocking bronchus
- bronchoscopy or esophagoscopy with removal

Deep Neck Space Infection

Definition
- most commonly arise from an infection of mandibular teeth, tonsils, parotid gland, deep cervical lymph nodes, middle ear, or the sinuses
- often a rapid onset and may progress to fatal complications

Etiology
- usually mixed aerobes and anaerobes that represent the flora of the oral cavity, upper respiratory tract, and certain parts of the ears and eyes

These investigations should be obtained carefully and the surgeon should consider accompanying the patient, as the worst place to lose an airway is during imaging

Clinical Features
- sore throat or pain and trismus
- dysphagia and odynophagia
- stridor and dyspnea
- late findings may include dysphonia and hoarseness
- swelling of the face and neck, erythema
- asymmetry of the oropharynx with purulent oral discharge
- fever, lymphadenopathy

Ludwig's angina is the prototypical infection of the submandibular and sublingual space

Diagnosis
- CBC with differential
- lateral cervical view plain radiograph
- CT
- MRI

Treatment
- secure the airway
- surgical drainage
- maximum doses of IV systemic antimicrobials regimens according to the site of infection

Common Medications

Table 21. Antibiotics

Generic Name (Brand Name)	Dose	Indications	Notes
Amoxicillin (Amoxil®, Amoxi®, Amox®)	Adult: 500 mg PO TID Children: 75-90 mg/kg/d in 2 divided doses	*Streptococcus, Pneumococcus, H. influenzae, Proteus* coverage	May cause rash in patients with infectious mononucleosis
piperacillin with tazobactam (Zosyn®)	3 g PO q6 h	Gram-positive and negative aerobes and anaerobes plus *Pseudomonas* coverage	May cause pseudomembranous colitis
ciprofloxacin (Cipro®, Ciloxan®)	500 mg PO BID	*Pseudomonas*, streptococci, methicillin-resistant *Staphylococcus aureus* (MRSA), and most Gram-negative; no anaerobic coverage	Animal studies suggest that systemic quinolones may cause cartilage necrosis in children
Erythromycin (Erythrocin®, EryPed®, Staticin®, T-Stat®, Erybid®, Novorythro Encap®)	500 mg PO QID	Alternative to penicillin	Ototoxic

Table 22. Otic Drops

Generic Name (Brand Name)	Dose	Indications	Notes
Ciprofloxacin (Ciprodex®)	4 gtt in affected ear BID	For OE and complications of OM *Pseudomonas*, streptococci, MRSA, and most Gram-negative; no anaerobic coverage	
neomycin, polymyxin B sulfate, and hydrocortisone (Cortisporin Otic®)	5 gtt in affected ear TID	For OE Used for inflammatory conditions which are currently infected or at risk of bacterial infections	May cause HL if placed in inner ear
hydrocortisone and acetic acid (VoSol HC®)	5-10 gtt in affected ear TID	For OM	Bactericidal by lowering pH
tobramycin and dexamethasone (TobraDex®)	5-10 gtt in affected ear BID	For chronic suppurative OM	Risk of vestibular or cochlear toxicity
Locacorten-Vioform Ear Drops®	2-3 gtt in affected ear BID	For OE, Otomycosis	

Table 23. Nasal Sprays

Generic Name (Brand Name)	Indications	Notes
Steroid		
flunisolide (Rhinalar®) budesonide (Rhinocort®) triamcinolone (Nasacort®) beclomethasone (Beconase®) mometasone furoate, monohydrate (Nasonex®) fluticasone furoate (Avamys®, Flonase®) ciclesonide (Omnaris®)	Allergic rhinitis Chronic sinusitis	Requires up to 4 wk of consistent use to have effect Long-term use Dries nasal mucosa; may cause minor bleeding Patient should stop if epistaxis May sting Flonase® and Nasonex® not absorbed systemically
Antihistamine		
levocabastine (Livostin®)	Allergic rhinitis	Immediate effect Discontinue if no effect by day 3 Use during allergy season
Decongestant		
xylometazoline (Otrivin®) oxymetazoline (Dristan®) phenylephrine (Neosynephrine®)	Acute sinusitis Rhinitis	Careful if patient has HTN Short-term use (<5 d) If long-term use, can cause decongestant addiction (i.e. rhinitis medicamentosa)
Antibiotic/Decongestant		
framycetin, gramicidin, phenylephrine (Soframycin®)	Acute sinusitis	
Anticholinergic		
ipratropium bromide (Atrovent®)	Vasomotor rhinitis	Careful not to spray into eyes as it can cause burning or precipitation of narrow angle glaucoma Increased rate of epistaxis when combined with topical nasal steroids
Lubricants		
saline, NeilMed®, Rhinaris®, Secaris®, Polysporin®, Vaseline®	Dry nasal mucosa	Use PRN Rhinaris® and Secaris® may cause stinging
Combination		
azelastine hydrochloride (antihistamine) and fluticasone propionate (steroid) (Dymista®)	Allergic rhinitis

Landmark Otolaryngology - Head and Neck Surgery Trials

Trial Name	Reference	Clinical Trial Details
Acute Otitis Media		
Shortened Antimicrobial Treatment for Acute Otitis Media in Young Children	NEJM 2016; 375:2446-2456	**Title**: Shortened Antimicrobial Treatment for Acute Otitis Media in Young Children **Purpose**: To study the potential of limiting the duration of antimicrobial treatment among children with acute otitis media to prevent antimicrobial resistance. **Methods**: Children with acute otitis media were assigned to 2 groups. 1 group received amoxicillin-clavulanate for 10 d, the other group received a reduced duration of 5 d. Rate of clinical response, recurrence, and nasopharyngeal colonization were measured. **Results**: Children treated with amoxicillin-clavulanate for 5 d had higher rates of clinical failure than those treated for the full duration. Mean symptoms scores over from d 6-14 were 1.61 in the 5 d group and 1.34 in the 10 d group. **Conclusions**: 10 d of amoxicillin-clavulanate had more favourable outcomes and no increase in adverse events or antimicrobial resistance compared to a 5 d course in children ages 6 mo-2 yr.
Effect of Antimicrobial Treatment of Acute Otitis Media on the Daily Disappearance on Middle Ear Effusion	JAMA Pediatr. 2014;168(7):635-641	**Title**: Effect of Antimicrobial Treatment of Acute Otitis Media on the Daily Disappearance on Middle Ear Effusion **Purpose**: To study the effect of antimicrobial treatment on the duration of middle ear effusion (MEE) and hearing impairment. **Methods**: Children were assigned to either have 40mg/kg of amoxicillin-clavulanate or a placebo mixture for 7 d. The primary outcome measure was time till disappearance of MEE. **Results**: MEE disappeared 2 wk earlier in the antimicrobial group, than in the placebo group (2.7 wk vs. 4.7 wk, respectively). **Conclusions**: Treatment with amoxicillin-clavulanate reduced the duration of middle ear effusion compared to placebo in children with acute otitis media.
Head and Neck Malignancy		
Elective versus Therapeutic Neck Dissection in Node-Negative Oral Cancer	NEJM 2015; 373(6):521-9	**Title**: Elective versus Therapeutic Neck Dissection in Node-Negative Oral Cancer **Purpose**: To evaluate survival after elective neck dissection vs therapeutic neck dissection in patients with lateralized stage T1 or T2 oral squamous-cell carcinomas. **Methods**: A prospective, randomized, controlled trial that evaluated survival after elective node dissection vs therapeutic node dissection. Overall survival and disease-free survival were used as primary and secondary endpoints, respecitvely. **Results**: At 3 yr, elective node dissection resulted in more survival (80%), than therapeutic neck dissection (67.5%). As well, at 3 yr, elective node dissection patients had a higher rate of disease free survival compared to those in the therapeutic surgery group (69.5% vs. 45.9%). **Conclusions**: Among patients with early-stage OSCC, elective neck dissection resulted in higher rates of overall and disease-free survival.
PET-NECK	NEJM 2016; 374:1444-1454	**Title**: PET-CT Surveillance versus Neck Dissection in Advanced Head and Neck Cancer **Purpose**: To compare the usefulness of planned neck dissection versus PET-CT-guided surveillance in patients with nodal stage N2 or N3 SCC. **Methods**: Patients with N2 or N3 neck disease were randomly assigned to either a neck dissection (planned surgery group) or PET-CT 12 weeks after chemoradiotherapy completion (surveillance group). The primary endpoint was overall survival. **Results**: The 2-yr survival rate was 84.9% (95% CI, 80.7 to 89.1) in the surveillance group and 81.5% (95% CI, 76.9 to 86.3) in the surgery group. The hazard ratio slightly favored PET-CT-guided surveillance and indicated noninferiority (upper boundary of the 95% CI for the hazard ratio, <1.50; P=0.004). **Conclusions**: PET-CT-guided surveillance is noninferior to planned neck dissection for overall survival in N2 or N3 SCC of the head and neck.
CheckMate 141	NEJM 2016; 375:1856-1867	**Title**: Nivolumab for Recurrent Squamous-Cell Carcinoma of the Head and Neck **Purpose**: To compare the overall survival of patients with platinum-refractory SCC of the head and neck treated with nivolumab versus standard therapy. **Methods**: Patients with recurrent SCC of the head and neck and disease progression within 6 mo after platinum-based chemotherapy received either nivolumab or standard systemic therapy (methotrexate, docetaxel, or cetuximab). The primary endpoint was overall survival. **Results**: Median overall survival was 7.5 mo (95% CI, 5.5 to 9.1) in the nivolumab group compared to 5.1 mo (95% CI, 4.0 to 6.0) in the standard therapy group. Survival is significantly longer with nivolumab (hazard ratio for death, 0.70; 97.73% CI, 0.51 to 0.96; P=0.01). **Conclusions**: Treatment with nivolumab resulted in longer overall survival than treatment with standard therapy in platinum-refractory, recurrent squamous-cell carcinoma of the head and neck.
Sleep-Disordered Breathing		
KATE	JAMA Otolaryngol Head Neck Surg. 2020;146(7):647-654	**Title**: Effectiveness of Adenotonsillectomy vs. Watchful Waiting in Young Children With Mild to Moderate Obstructive Sleep Apnea: A Randomized Clinical Trial **Purpose**: To determine whether adenotonsillectomy is more effective than watchful waiting for treating healthy children with mild to moderate OSA. **Methods**: 60 children ages 2 to 4 with mild to moderate OSA were randomized to either adenotonsillectomy or watchful waiting. The primary outcome was the difference in mean obstructive apnea-hypopnea index (OAHI) score change between the two groups. **Results**: Both groups had a reduced mean OAHI score with a small intergroup difference (−1.0; 95% CI, −2.4 to 0.5). Children with moderate OSA showed a meaningful intergroup difference in mean OAHI score change, favouring adenotonsillectomy (−3.1; 95% CI, −5.7 to −0.5). **Conclusions**: Otherwise healthy children ages 2-4 with mild OSA may benefit from watchful waiting, while children with moderate OSA should be considered for surgical treatment.
CHAT	NEJM 2019; 20(9):1273-1285	**Title**: A Randomized Trial of Adenotonsillectomy for Childhood Sleep Apnea **Purpose**: To investigate the benefits of adenotonsillectomy vs. supportive care on children with obstructive sleep apnea. **Methods**: Children ages 5-9 yr, with obstructive sleep apnea syndrome were randomized to adenotonsillectomy or a strategy of watchful waiting. Polysomnographic, cognitive, behavioral, and health outcomes were assessed at baseline and again at 7 mo. **Results**: Attention and executive function scores from baseline did not change significantly in the adenotonsillectomy group vs. the watchful waiting group (7.1±13.9 vs. 5.1±13.4, respectively). Significant differences from baseline in behavioural, and quality of life were found in the adenotonsillectomy group. Normalization of polysomnographic findings were found in more of the adenotonsillectomy than the watchful waiting group (79% vs. 46%). **Conclusions**: Surgical treatment for obstructive sleep apnea in children ages 5-9 did not significantly improve attention or executive function but did improve behaviour, quality of life, and polysomnographic findings compared to watchful waiting.

P Paediatrics

Acronyms

AAP	American Academy of Pediatrics
ABG	arterial blood gas
ACE	angiotensin converting enzyme
ACEI	angiotensin converting enzyme inhibitor
ADH	antidiuretic hormone
AGA	appropriate for gestational age
ALL	acute lymphoblastic leukemia
ALPS	autoimmune lymphoproliferative syndrome
AML	acute myelogenous leukemia
ANA	antinuclear antibody
AOM	acute otitis media
ARB	angiotensin receptor blocker
ARBD	alcohol-related birth defects
ARND	alcohol-related neurodevelopmental disorder
ASD	atrial septal defect
ASOT	antistreptolysin-o titre
ATN	acute tubular necrosis
AVM	arteriovenous malformation
BRUE	brief resolved unexplained events
CAH	congenital adrenal hyperplasia
CAS	Children's Aid Society
CDGP	constitutional delay of growth and puberty
CF	cystic fibrosis
CFTR	cystic fibrosis transmembrane conductance regulator
CHD	congenital heart defect
CML	chronic myelogenous leukemia
CMV	cytomegalovirus
CP	cerebral palsy
CPAP	continuous positive airway pressure
CPS	Canadian Paediatric Society
DAT	direct antiglobulin test
DDAVP	1-desamino-8-D-arginine vasopressin
DI	diabetes insipidus
DIC	disseminated intravascular coagulation
DKA	diabetic ketoacidosis
DMARD	disease modifying antirheumatic drug
DS	Down syndrome
DSD	disorder of sexual differentiation
EBV	Epstein-Barr virus
Echo	echocardiogram
FAS	fetal alcohol syndrome
FASD	fetal alcohol spectrum disorder
FISH	fluorescent *in situ* hybridization
FSS	familial short stature
FTT	failure to thrive
GA	gestational age
GAS	group A *Streptococcus*
GBM	glomerular basement membrane
GBS	group B *Streptococcus*
GERD	gastroesophageal reflux disease
GN	glomerulonephritis
GSD	glycogen storage disease
GTPAL	Gravidity Term Preterm Abortion Living
HBsAg	hepatitis B surface antigen
HDNB	hemorrhagic disease of the newborn
HEEADSSS	Home Education/Employment Eating Activities Drugs Sexuality Suicide/depression Safety/violence
Hib	*Haemophilus influenzae* type b
HIDA	hepatobiliary iminodiacetic acid
HIE	hypoxic ischemic encephalopathy
HPA	human platelet antigen
HRV	human rotavirus
HSP	Henoch-Schönlein purpura
HSV	herpes simplex virus
HUS	hemolytic uremic syndrome
IBD	inflammatory bowel disease
IBW	ideal body weight
ICH	intracranial hemorrhage
ITP	immune thrombocytopenic purpura
IUGR	intrauterine growth restriction
IVH	intraventricular hemorrhage
IVIg	intravenous immunoglobulin
JIA	juvenile idiopathic arthritis
LAH	left atrial hypertrophy
LBW	low birth weight
LGA	large for gestational age
LLSB	lower left sternal border
LMN	lower motor neuron
LOC	level of consciousness
LP	lumbar puncture
LRTI	lower respiratory tract infection
LV	left ventricle
LVH	left ventricular hypertrophy
MAS	meconium aspiration syndrome
MCAD	medium-chain acyl-CoA dehydrogenase
MCD	minimal change disease
MDI	metered dose inhaler
MSUD	maple syrup urine disease
NCS	nerve conduction study
NEC	necrotizing enterocolitis
NF	neurofibromatosis
NICU	neonatal intensive care unit
NS	normal saline
OCP	oral contraceptive pill
ORT	oral rehydration therapy
OSA	obstructive sleep apnea
PAC	premature atrial contraction
PCOS	polycystic ovarian syndrome
PDA	patent ductus arteriosus
PKU	phenylketonuria
PPHN	persistent pulmonary hypertension of newborn
PPV	positive pressure ventilation
PUVA	psoralen + UVA
RAD	right axis deviation
RAS	renal artery stenosis
RBBB	right bundle branch block
RDS	respiratory distress syndrome
RF	rheumatoid factor
Rh	Rhesus factor
RL	Ringer's lactate
RSV	respiratory syncytial virus
RUSB	right upper sternal border
RVH	right ventricular hypertrophy
RVOTO	right ventricular outflow tract obstruction
SEM	systolic ejection murmur
SGA	small for gestational age
SIADH	syndrome of inappropriate antidiuretic hormone
SIDS	sudden infant death syndrome
STEC	Shiga toxin-producing *E. coli*
SVT	supraventricular tachycardia
TEF	tracheoesophageal fistula
TM	tympanic membrane
TPN	total parenteral nutrition
TTN	transient tachypnea of the newborn
UMN	upper motor neuron
URTI	upper respiratory tract infection
UVA	ultraviolet A
VCUG	voiding cystourethrogram
VKDB	vitamin K deficiency bleeding
VSD	ventricular septal defect
VUR	vesicoureteral reflux
WPW	Wolff-Parkinson-White

Paediatric Quick Reference Values

Table 1. Normal HR and RR at Various Ages

Age (yr)	Pulse (bpm)	Respiratory Rate (br/min)
Neonate (<28 d)	100-205	30-53
Infant (1-12 mo)	100-190	
Toddler (1-2 yr)	98-140	22-37
Preschool (3-5 yr)	80-120	20-28
School-age (6-11 yr)	75-118	18-25
Adolescent (12-15 yr)	60-100	12-20

Table 2. Normal sBP at Various Ages

Age	sBP (mmHg)
Birth <1 kg (12 h)	39-59
Birth 3 kg (12 h)	60-76
Neonate (96 h)	67-84
Infant (1-12 mo)	72-104
Toddler (1-2 yr)	86-106
Preschool (3-5 yr)	89-112
School-age (6-9 yr)	97-115
Preadolescent (10-11 yr)	102-120
Adolescent (12-15 yr)	110-131

Table 3. Normal Temperature Ranges

Method	Normal temperature range	Fever
Rectal	36.6°C to 38°C	≥38°C
Ear	35.8°C to 38°C	≥38°C
Oral	35.5°C to 37.5°C	≥37.5°C
Axillary	36.5°C to 37.5°C	≥37.5°C

Canadian Immunization Guide
National Advisory Committee on Immunization. Canadian Immunization Guide (CIG). Last Modified 2021. Public Health Agency of Canada, 2006. Available at: https://www.canada.ca/en/public-health/services/canadian-immunization-guide.html

Table 4. Temperature Measurement Technique Recommendations

Age	Suggested technique
Birth to 2 yr	1. Rectal (definitive) 2. Axillary (screening low risk children)
Over 2 yr to 5 yr	1. Rectal (definitive) 2. Axillary, Tympanic (or Temporal Artery if in hospital) (screening)
Older than 5 yr	1. Oral (definitive) 2. Axillary, Tympanic (or Temporal Artery if in hospital) (screening)

Primary Care

Visit Overview

- schedule
  - newborn (within 24-48 h post-discharge), 1, 2, 4, 6, 9, 12, 15, 18, 24 mo
  - annually between ages 2-5; every 1-2 yr between ages 6-18
- content
  - history and physical exam including growth, development, and nutrition
  - routine immunizations
  - counselling and anticipatory guidance
  - see evidence based clinical tools such as Rourke Baby Record and Greig Health Record for more information

Standard Paediatric History

- **BINDS**: **B**irth, **I**mmunization, **N**utritional, **D**evelopmental, **S**ocial
- ID: name, age, major chronic medical concerns
- chief complaint (CC)/reason for referral (RFR)
- HPI: child and caregiver
  - OPQRSTU
  - recent travel, sick contacts
- obstetrical history
  - prenatal/pregnancy history
    - conception
    - GTPAL
    - screening: blood group, Rh, DAT, HBsAg, rubella, syphilis, HIV, GBS
    - genetic screening: maternal serum screening (MSS), first trimester screening (FTS), integrated prenatal screening (IPS), amniocentesis, special tests
    - ultrasounds
    - **complications:** illnesses, infections, bleeding, gestational diabetes (GDM), gestational hypertension (GHTN)
    - medications, vitamins, iron, smoking, drinking, drug use
  - labour and delivery or birth history, and why
    - gestational age at birth, birth weight
    - labour **complications:** prolonged rupture of membranes, maternal fever, fetal tachycardia, meconium
    - spontaneous vaginal delivery, interventions required: forceps, vacuum, caesarean delivery (CD)
    - medications used during labour
    - resuscitation: APGARs
    - length of hospital stay, NICU stay
- past medical history
  - hospitalizations, ED visits, past surgeries, chronic illnesses, accidents or injuries, community resources/services involved or referrals in place, other specialists involved in care
- medications
- allergies
- immunizations (including contraindications, such as previous anaphylaxis, or immunosuppression)
- developmental history
  - meeting major milestones
  - behavioural concerns
- nutritional history
  - breast vs. formula feeding
  - milk intake
  - solids, variety, etc.
- family history
  - consanguinity, recurrent pregnancy losses, early childhood deaths

According to the Centers for Disease Control and Prevention (CDC), the weight of currently available scientific evidence does not support the hypothesis that MMR vaccine causes either autism or IBD. The landmark paper linking autism to the MMR vaccine (Lancet 1998;351:637-641) was retracted due to false claims in the article (Lancet 2010;375:445)

Adverse Reactions Associated with Any Vaccine
- **Local**: induration, tenderness, redness, swelling
- **Systemic**: fever, rash, irritability
- **Allergic**: urticaria, rhinitis, anaphylaxis

Contraindication:
- Moderate/severe illness ± fever
- Allergy to vaccine component
- No need to delay vaccination for mild URTI

Vaccination in Cases of Asplenia or Hyposplenia (such as Sickle Cell Disease)
- Should receive all routine immunizations, including the yearly influenza vaccine
- No vaccines are contraindicated, though live vaccines can be contraindicated in immunodeficiencies such as DiGeorge syndrome (22q11.2 deletion)
- Susceptible to infection by encapsulated bacteria ("SHiNE KISS" –***S. pneumoniae, H. influenzae, N. meningitidis, E. coli, Klebsiella, Salmonella***, Group B Strep), so must add:
  - Quadrivalent conjugated Meningococcal C vaccine (Men-C-ACYW) and Meningococcal B vaccine (4CMenB) at time of diagnosis if ≥2 mo (2-4 doses given at least 8 wk apart) with booster every 5 yr thereafter
  - Can omit routine Meningococcal-C-Conjugate at 12 mo if received Men-C-ACYW and expected to receive a second dose within 8 wk
  - Pneumococcal polysaccharide vaccine (Pneu-P-23) at ≥2 yr and single booster ≥5 yr after first dose
- Pneumococcal conjugate vaccine (Pneu-C-13) 1-2 doses 8 wk apart if ≥12 mo at time of diagnosis
  - Consider single booster Hib at >5 yr

- social history
  - who lives at home? Siblings?
  - does the child attend daycare or school? Primary care givers?
  - school adjustment, friends, activities, safety, stability, stressors
  - HEEADSSS history for adolescents
  - ITHELPS – income, transportation, home, education, legal status, personal safety, support

Routine Immunization

Table 5. Publicly Funded Immunization Schedule for Ontario

	DTaP-IPV-Hib	TdaP-IPV	Pneu-C-13	Rot-5	Men-C-C	MMR	Var	MMRV	Men-C-ACYW	HepB	HPV-9	Tdap	Inf
2 mo	✓IM		✓IM	✓PO									
4 mo	✓IM		✓IM	✓PO ✓PO									
6 mo	✓IM			✓PO									
12 mo			✓IM		✓IM	✓SC							
15 mo							✓SC						
18 mo	✓IM												
4-6 yr*		✓IM						✓SC					
Grade 7									✓IM	✓IM 3 doses (0,1,6 mo)	✓IM 2 doses (0,6 mo)		
14-16 yr												✓IM	
Every autumn (beginning at age 6 mo)													✓IM

IM = intramuscular; PO = per oral; SC = subcutaneous
* Preferably given at 4 yr of age
DTaP-IPV-Hib = diphtheria, tetanus, acellular pertussis, inactivated polio, Haemophilus influenzae type b vaccine (i.e. Pediacel®); TdaP-IPV = diphtheria, tetanus, acellular pertussis, inactivated polio vaccine (i.e. Adacel®-Polio); HepB = hepatitis B vaccine; HPV-4 = human papillomavirus vaccine; Inf = influenza vaccine;
MMR = measles, mumps, rubella vaccine; Men-C-C = meningococcal c conjugate vaccine; Men-C-ACYW = meningococcal vaccine; MMRV = measles, mumps, rubella, varicella vaccine; Pneu-C-13 = pneumococcal 13-valent conjugate vaccine; Rot-5 = rotavirus oral vaccine; Var = varicella vaccine

Table 6. Adverse Reactions and Contraindications of Routine Immunizations

Vaccine	Adverse Reaction	Contraindication
TdaP-IPV	Prolonged crying Hypotonic unresponsive state (rare) Seizure on day of vaccine (rare)	Evolving unstable neurologic disease Hyporesponsive/hypotonic following previous vaccine Anaphylactic reaction to neomycin or streptomycin
Rot-5	Cough Diarrhea, vomiting Fever Intussusception	History of intussusception Immunocompromised Abdominal disorder (e.g. Meckel's diverticulum)
MMR	Measles-like rash (7-14 d) Lymphadenopathy, arthralgia, arthritis Parotitis (rare) Especially painful injection Transient thrombocytopenia (1/30000)	Pregnancy Immunocompromised infants (except healthy HIV positive children) Anaphylactic reaction to gelatin
Var	Mild varicella-like papules or vesicles; 2 wk may get local or generalized rash	Pregnant or planning to get pregnant within 3 mo Anaphylactic reaction to gelatin
HepB		Anaphylactic reaction to Baker's yeast
MMRV	Same as MMR and Var vaccines	Same as MMR and Var vaccines
DTaP		1st trimester pregnancy
Inf	Malaise, myalgia Febrile seizure when given with Pneu-C-13 or DTaP Hypersensitivity reaction	<6 mo of age Immunocompromised Egg-allergic individuals – Live attenuated influenza vaccine is not recommended for those with an egg allergy. In these individuals, trivalent or quadrivalent vaccine can be given in an environment where anaphylaxis can be managed
HPV-9	Pruritus	
Men-B*		Anaphylactic reaction to Men-B vaccine or its components in the past
Men-C-ACYW	Syncope (rare)	Anaphylactic reaction to Men-B vaccine or its components in the past

* Currently only publicly funded for select groups (asplenia, antibody/complement deficiencies, cochlear implant recipients, HIV, close contacts with infected individuals)
DTaP = diphtheria, tetanus, acellular pertussis vaccine; TdaP-IPV = diphtheria, tetanus, acellular pertussis, inactivated polio vaccine (i.e. Adacel®-Polio); HepB = hepatitis B vaccine; HPV-4 = human papillomavirus vaccine; Inf = influenza vaccine; MMR = measles, mumps, rubella vaccine; Men-B = multicomponent meningococcal B vaccine; Men-C-C = meningococcal c conjugate vaccine; Men-C-ACYW = meningococcal vaccine; MMRV = measles, mumps, rubella, varicella vaccine; Rot-5 = rotavirus oral vaccine; Var = varicella vaccine

Injection site
Infants (<12 mo): anterolateral thigh

A Systematic Review of the Effect of Rotavirus Vaccination on Diarrhea Outcomes Among Children Younger Than 5 Years
Pediatr Infect Dis J 2016;35(9):992-998
Purpose: To review evidence of rotavirus vaccine efficacy and effectiveness by Millennium Development Goal Region.
Method: RCTs and observational studies on rotavirus vaccine in children <5 y/o were included in this review. Primary outcomes included rotavirus diarrhea or diarrhea of unspecified etiology. Secondary outcomes included diarrhea episodes of any severity, and severe diarrhea episodes, hospitalization, and death.
Results: 48 studies were eligible for inclusion in this review. Rotavirus vaccine was found to be effective and efficacious. Across all millennium development regions rotavirus vaccine prevented rotavirus diarrhea, severe rotavirus diarrhea, and rotavirus hospitalization. The vaccine also reduced severe diarrhea and diarrhea related hospitalization in general.

- adverse effects following immunization: must be reported to the local or regional health unit when the event: has a temporal association with a vaccine, has no other clear cause at the time of reporting, meets one or more of the seriousness criteria, is unexpected
- temperature regulation in vaccine storage: cold chain generally +2 to +8°C

Modifications to the Routine Vaccination Schedule
- catch-up immunization schedules for children not previously immunized
- additional immunizations for children at-risk due to underlying medical conditions
- update Dec 2020: current Ontario catch-up program for HPV vaccine - 2-3 doses for Grades 8-11 (males) and Grades 8-12 (females)

Immunization of Immunocompromised Patients
- susceptibility to infection and vaccine response varies
- individualized vaccine schedule based on patient's immune status
- inactivated vaccines: may be administered if indicated, duration of immunity may be reduced
- live-attenuated vaccines: avoid if severely immunocompromised or if uncertain of immune status, may be used if mildly immunocompromised
- serologic testing and re-immunization: immune response may be inadequate, consider post-immunization antibody titres if appropriate, positive serologic test in may be due to immunoglobulin therapy or maternal antibody (infants <18 mo)

Vaccine-Hesitant Parents
- healthcare professional vaccine advice plays a key role in parental decision-making
  - do not dismiss vaccine-hesitant families from your practice
- use a presumptive approach (for giving the vaccine) and motivational interviewing
  - use open-ended questions and listen to parent concerns and opinions - do not assume the health concerns of the parent
  - address concerns non-judgmentally and non-confrontationally; validate why parents may hold their belief
  - use compelling stories of vaccine-preventable disease
- communicate clearly to discuss disease risks and vaccine benefits and risks
- address immunization pain
- community protection (herd immunity)
  - "wait and see" approach to vaccinate in an outbreak scenario is not advisable
  - promote altruism - not receiving immunization can have consequences for others
- parents who refuse to immunize their children need to be informed of associated risks of diseases and responsibilities - considerations include:
  - protection of child from acquiring illnesses (e.g. vaccine, avoid sick contacts)
  - not vaccinating risks the health of others (weakened immune system, chronic conditions, newborns, elderly)
  - inform healthcare professionals of lack of vaccination when child is sick
  - if a vaccine-preventable disease is in your community: get vaccine, may be required to stay away from school, consider disease-specific risks, learn what symptoms to look out for
  - tetanus (>10% mortality) does not have community protection
  - travel - vaccines specific to geographical regions, refused permission to travel

Growth and Development

Growth
- growth is not linear
  - most rapid growth during first 2 yr and at puberty
- measurement of growth
  - WHO Growth Charts used to monitor growth in infants and children
  - premature infants (<37 wk) use Fenton Curve to assess for small for gestational age (SGA) vs. large for gestational age (LGA); corrected GA until 2 yr
  - body proportion = upper/lower segment ratio (use symphysis pubis as midpoint)
    - newborn = 1.7, adult male = 0.9, adult female = 1.0

Average Growth Parameters

Table 7. Parameters of Average Growth at Birth

	Normal	Growth	Comments
Birth Weight	3.25 kg (7 lbs)*	Gain 20-30 g/d (term neonate) 2 x birth wt by 4-5 mo 3 x birth wt by 1 yr 4 x birth wt by 2 yr	Weight loss (up to 10% of birth weight) in first 7 d of life is normal Neonate should regain birth weight by ~10-14 d
Length/Height	50 cm (20 in)*	25 cm in 1st yr 12 cm in 2nd yr 8 cm in 3rd yr, then 4-7 cm/yr until puberty 8-12 cm/yr in adolescence 1/2 adult height at 2 yr	Measure supine length until 2 yr, then measure standing height
Head Circumference	35 cm (14 in)*	2 cm/mo for 1st 3 mo 1 cm/mo at 3-6 mo 0.5 cm/mo at 6-12 mo	Measure around occipital, parietal, and frontal prominences to obtain the greatest circumference

* note these are averages, and may differ based on ethnicity and gestational age

Reflexes

Table 8. Developmental or Primitive Reflexes

Reflex	Maneuver to Elicit Reflex	Appropriate Reflex Response	Age of Disappearance
Moro	Infant placed semi-upright, head supported by examiner's hand, sudden withdrawal of supported head with immediate return of support	Abduction and extension of the arms, opening of the hands, followed by flexion and adduction of arms	4-6 mo
Galant	Infant held in ventral suspension and one side of back is stroked along paravertebral line	Pelvis will move in the direction of stimulated side	2-3 mo
Grasp	Placement of examiner's finger in infant's palm	Flexion of infant's fingers	3-4 mo
ATNR	Turn infant's head to one side	"Fencing" posture (extension of ipsilateral arm and leg, flexion of contralateral arm and leg)	4-6 mo
Stepping	Dorsal surface of infant's foot placed touching edge of table	Flexion followed by extension of ipsilateral limb up onto table (resembles primitive walking)	Variable
Rooting	Tactile stimulus near mouth	Infant turns head and opens mouth to suck on same side that cheek was stroked	2-3 mo
Lateral Propping	Tilt infant to side while in sitting position	Ipsilateral arm extension, present by 6-8 mo	Does not disappear

ATNR = asymmetric tonic neck reflex

Abnormal Reflex Response (primitive reflex response present in infancy; tendon reflex response always present)

- Primitive reflex responses are abnormal if: absent during neonatal period; asymmetric; or persistent after 4-6 mo (e.g. cerebral palsy)
- Tendon reflex responses: asymmetry suggests focal motor lesions (e.g. brachial plexus injury) and absence or hyper-reflexia may suggest CNS abnormality
- Upgoing plantar reflex (Babinski's sign) normal in infants up to 2 yr

Developmental Milestones

Table 9. Developmental Milestones

Age*	Gross Motor	Fine Motor	Speech and Language	Cognitive/ Problem Solving	Social/Emotional
Newborn	Primitive reflexes: step, place, Moro, Babinski, ATNR; flexed posture	Primitive reflex: grasp	Primitive reflexes: root, suck; orients to sound; variable cries	Fixes and follows slow horizontal arc; prefers contrast, colours, faces, high-pitched voices; visual focal length ~10"	Bonding between parent and child
2 mo	Raises head 45° when prone	Hands open half the time, bats at objects	Turns to voice, cooing	Prefers familiar caregiver	Social smile
4 mo	Rolls prone to supine, sits with support, raises head up 90° and lifts chest when prone	Palmar grasp, reaches and obtains items, brings objects to midline	Squeals, laughs	Purposeful sensory exploration of objects (eyes, hands, mouth), anticipates routines	Explores parent's face
6 mo	Tripod sit, rolls both ways, postural reflexes	Transfers objects from hand to hand, raking grasp	Babbles (nonspecific)	Stranger anxiety, looks for dropped object	Expresses emotions: happy, sad, mad; memory for ~24 hr
9 mo	Sits well without support, crawls (not all), pulls to stand	Inferior pincer grasp, pokes objects	Mama, dada" Gestures "bye bye", "up", gesture games	Plays games (e.g. peek-a-boo) Object permanence	Separation anxiety
12 mo	Walks a few steps, wide gait	Fine pincer (fingertips), finger-feeds cheerios, voluntary release	1 word with meaning (besides mama, dada), responds to own name, follows 1-step command with gesture	Uses objects functionally, cause and effect, trial and error, imitates	Points at wanted items, narrative memory
15 mo	Walks without support, crawls up stairs/steps	Stacks 2 blocks, uses spoon	4-5 words, follows 1-step command without gesture, 1 body part	Looks for moved hidden object if saw it being moved	Shared attention: points at interesting items to show to parent
18 mo	Runs, stoops and recovers	Tower of 4 blocks, scribbling, fisted pencil grasp, removes clothing	15-25 words 3 body parts	Symbolic play with doll or bear	Parallel play
24 mo	Jumps on two feet, up and down stairs 'marking time'	Tower of 6 blocks, handedness established, uses utensil	2-3 word phrases, uses "I, me, you," 50% intelligible, understands 2-step commands, 50+ words	New problem-solving strategies without rehearsal	Testing limits, tantrums, negativism ("no!"), possessive ("mine!")
3 yr	Rides tricycle, climbs up stairs alternating feet	Toilet trained, undresses, draws circle and cross (+)	3-step commands, 3-4 word phrases, "W" questions ("why?"), 200 words, 75% intelligible	Identifies shapes, counts to 3, simple time concepts	Cooperative play, role play (pretend play), separates easily, sharing
4 yr	Hops on 1 foot, climbs down stairs 1 foot per step	Uses scissors, buttons clothes	Speech 100% intelligible, uses past tense, tells a story	Identifies 4 colours, counts to 4	Has a preferred friend, elaborate fantasy play
5 yr	Skips, rides bicycle	Prints name, ties shoelaces, tripod pencil grasp	Fluent speech, future tense	Counts to 10 accurately, recites ABCs	Has group of friends

*If premature, use corrected GA until 2 yr

Developmental Red Flags
- Gross motor: not walking at 18 mo; rolling too early at <3 mo
- Fine motor: hand preference at <18 mo
- Speech: <6 words at 18 mo
- Social: not smiling at 4 mo; not pointing at 15-18 mo
- See the Nipissing District Developmental Screen for a checklist of important 18 mo milestones: www.ndds.ca
- Regression (i.e. loss of a previously acquired skill) is a red flag at any age

Nutrition

Dietary Requirements

Weight	<10 kg	10-20 kg	>20 kg
Needs	100 kcal/kg/d	1000 cal + 50 kcal/kg/d for each kg >10	1500 cal + 20 kcal/kg/d for each kg >20

Dietary Recommendations
- 0-6 mo: breast milk or formula
  - exclusive breast milk during first 6 mo recommended over formula unless contraindicated, up to 2 yr
  - breastfed infants require supplements: vitamin D (400 IU/d)
  - if not consuming iron-fortified cereals, meats, meat alternatives after 6 mo, at risk of iron deficiency: give iron (after at least 4 mo and before 6 mo)

See Landmark Paediatric Trials table for more information on LEAP trial, which details the benefits of early introduction of peanuts in decreasing prevalence of peanut allergies in children deemed at risk.

Dietary Exposures and Allergy Prevention in High-Risk Infants
Paediatr Child Health 2013;18(10):545-549
There is no evidence that restriction of highly allergenic foods is beneficial in the first year of life. Later introduction of peanut, fish, or egg does not prevent, and may increase the risk of developing food allergy. There is also no evidence that dietary restrictions during pregnancy or breastfeeding are protective to the child.

- >6 mo: solid food introduction – do not delay beyond 9 mo
  - 2-3 new foods per wk, wait at least 2 d in between each food to allow time for adverse reaction identification
    - common allergens: eggs, milk, mustard, peanuts, seafood, sesame, soy, tree nut, wheat
  - early introduction of highly allergenic foods is recommended
  - offer lumpy, soft-cooked, pureed, mashed textured foods
  - encourage self-feeding and introduce open cup (should be done by 18 mo)
- 9-24 mo: switch to homogenized (3.25%) cow's milk, offer 16oz/d if non-breast feeding
  - offer vegetables, fruit, grains, and full-fat milk in any order after iron-rich foods are given
  - provide up to 3 large feedings (meals) with 1-2 smaller feedings (snacks), depending on child's hunger/satiety cues
  - foods to avoid
    - honey until past 12 mo (risk of botulism)
    - added sugar, salt
    - excessive milk (i.e. maximum 500 mL or 16 oz/d after 1 yr) - associated with iron deficiency anemia
    - limit juice intake (not nutritious, too much sugar), maximum 4-6 oz (1/2 cup) daily
    - anything that is a choking hazard (chunks, round foods like grapes)
- 2-6 yr: switch to 2% milk (500 mL/d)
  - can maintain breastfeeding during this time complementary to solids

Breastfeeding

- content of breast milk
  - colostrum (first few days postpartum): clear, rich in nutrients (i.e. high protein, low fat), immunoglobulin
  - mature milk: 70:30 whey:casein ratio, fat from dietary butterfat, carbohydrate from lactose
- advantages
  - easily digested, low renal solute load
  - immunologic
    - reduction of acute illnesses (i.e. diarrhea, respiratory tract illnesses, acute otitis media) and may have longer term benefits
    - contains IgA, macrophages, active lymphocytes, lysozymes, lactoferrin (which inhibits *E. coli* growth in intestine)
    - lower pH promotes growth of *Lactobacillus* in GI tract
  - parent-child bonding
  - economical, convenient
- maternal contraindications
  - absolute contraindications: HIV, HTLV type I and II, infant galactosemia
  - relative contraindications: chemotherapy, radioactive compounds, or certain medications known to cross to breast milk with neonatal effects
  - active untreated TB (2 wk), active HSV-2 lesions on breast (can still feed expressed breast milk from unaffected breast)
  - OCPs are not a contraindication to breastfeeding (estrogen may decrease lactation, but is not dangerous to infant)
- if poor weight gain: consider dehydration or FTT and may consider formula supplementation if insufficient milk production or intake
- oral candidiasis (thrush): treat baby with antifungal such as nystatin and ensure all nipples, bottles, pacifiers are sanitized to avoid re-infection; can occur in breast or bottle-fed infants

Medications that Cross into Breast Milk
- Antimetabolites
- Chloramphenicol
- Diazepam
- Ergots
- Gold
- Metronidazole
- Tetracycline
- Lithium
- Cyclophosphamide

Signs of Inadequate Intake
- <6 wet diapers/d after first wk
- <7 feeds/d
- Sleepy or lethargic, sleeping throughout the night <6 wk
- Weight loss >10% of birth weight (past 10-14 d of life)
- Jaundice

Signs of Adequate Intake
- 1 wet diaper/d of age for first wk
- 1-2 black or dark green stools (meconium)/d on Day 1 and 2
- 3+ brown/green/yellow stools/d on Day 3 and 4
- 3+ yellow, seedy stools/d on Day 5+

Table 10. Common Formulas Compared to Breast Milk

Type of Nutrition	Indications	Content (as compared to breast milk)
Cow's Milk-Based (Enfamil®, Similac®)	Prematurity Transition to breastfeeding Contraindication to breastfeeding	Lower whey:casein ratio Plant fats instead of dietary butterfat
Fortified Formula	Low birth weight Prematurity	Higher calories and vitamins A, C, D, K May only be used in hospital due to risk of fat-soluble vitamin toxicity
Soy Protein (Isomil®, Prosobee®)	Galactosemia Desire for vegetarian/vegan diet*	Corn syrup solids or sucrose in place of lactose
Partially Hydrolyzed Proteins (Good Start®)	Delayed gastric emptying Risk of cow's milk protein allergy	Protein is 100% whey with no casein
Protein Hydrolysate (Nutramigen®, Alimentum®, Pregestimil®, Portagen®)	Malabsorption Food allergy including cow's milk protein allergy	Protein is 100% casein with no whey Corn syrup solids, sucrose, or tapioca starch instead of lactose Expensive
Amino Acid (Neocate®, PurAmino™)	Food allergy Short gut	Free amino acids (no protein) Corn syrup solids instead of lactose Very expensive
Metabolic	Inborn errors of metabolism	Various different compositions for children with galactosemia, propionic acidemia, etc.

* 10-35% of children with cow's milk protein allergy also have reactions to soy-based formula

Injury Prevention Counselling

- injuries are the leading cause of death in children >1 yr
- main causes: motor vehicle crashes, burns, drowning, falls, choking, infanticide

Table 11. Injury Prevention Counselling

0-6 mo	6-12 mo	1-2 yr	2-5 yr
Do not leave alone on bed, on changing table, or in tub Keep crib rails up Check water temperature before bathing Do not hold hot liquid and infant at the same time Check milk temperature before feeding Appropriate car seats are required before leaving hospital Avoid co-sleeping with infant	Install stair barriers Discourage use of walkers Avoid play areas with sharp-edged tables and corners Cover electrical outlets Unplug appliances when not in use Keep small objects, plastic bags, cleaning products, and medications out of reach Supervise during feeding Appropriate car seats	Never leave unattended Keep pot handles turned to back of stove Caution with whole grapes, nuts, raw carrots, hotdogs, etc. due to choking hazard No running while eating Appropriate car seats	Bicycle helmet Never leave unsupervised at home, driveway, or pool Teach bike safety, stranger safety, and street safety Swimming lessons (>4 yr), sunscreen (from 6 mo), fences around pools Appropriate car seats Ensure large devices (such as TVs) secured to walls

Note: This list is not exhaustive. For more details, see Rourke Baby Record (http://www.rourkebabyrecord.ca/downloads)

Circumcision

- elective procedure
  - CPS affirms that circumcision is not medically indicated, and does not recommend routine circumcision for every newborn male
  - often done for religious or cultural reasons
- benefits: prevention of phimosis and slightly reduced incidence of UTI, STI, balanitis, cancer of the penis
- complications (<1%): local infection, bleeding, urethral injury, meatal stenosis
  - complication rate increased in children compared with infants
- **contraindications**: presence of genital abnormalities (e.g. hypospadias) or known bleeding disorder

Newborn Male Circumcision
Paediatr Child Health 2015;20(6):311-320
The Canadian Paediatric Society and American Academy of Pediatrics have both previously indicated that circumcision of newborn males is not a medically indicated procedure. Some evidence has subsequently suggested decreased urinary tract infections and incidence of some sexually transmitted infections, including HIV, with circumcision. While such a benefit may be present in some boys and high-risk populations where the procedure may be considered in the context of reduction or treatment, the Canadian Paediatric Society continues to not recommend routine circumcision for every newborn male.

Common Complaints

Breath Holding Spells

- **clinical features**
  - cyanotic type (more common), usually associated with anger/frustration
  - pallid type, usually associated with pain/surprise
- **epidemiology:** 0.1-5% of healthy children 6 mo-4 yr, usually start during first year of life
- **etiology:** child is provoked (usually by anger, injury, or fear) ➔ holds breath and becomes silent ➔ spontaneously resolves or loses consciousness
- **management**
  - usually resolves spontaneously and rarely progresses to seizure; median age of remission is 4 yr, and almost all children stop by 8 yr
  - help child control response to frustration and avoid drawing attention to spell
  - may be associated with iron deficiency anemia, improves with supplemental iron
  - if episodes prolonged/frequent, triggered by non-traumatic stimuli, or if there is a family history of syncope or sudden death ➔ in-depth cardiac evaluation indicated - check for prolonged QT syndrome

Crying/Fussing Child

- common etiologies: functional (e.g. hungry, irritable), colic, trauma, illness
- history
  - description of baseline feeding, sleeping, crying patterns
  - infectious symptoms: fever, tachypnea, rhinorrhea, ill contacts
  - feeding intolerance: gastroesophageal reflux with esophagitis, N/V, diarrhea, constipation
  - physical injury (unintentional or non-accidental)
  - recent immunizations (vaccine reaction) or medications (drug reactions), including maternal drugs taken during pregnancy (neonatal withdrawal syndrome) and drugs that may be transferred via breast milk

- inconsistent history, pattern of numerous emergency department visits, difficult social living conditions (e.g. parental substance use, precarious living circumstances) can raise concerns for maltreatment
- consider broad array of possible underlying causes such as meningitis, sepsis, respiratory distress, constipation, etc.

Infantile Colic

- **clinical features:** unexplained paroxysms of irritability and crying for >3 h/d, >3 d/wk for >3 wk in an otherwise healthy, well-fed baby (rule of 3s - Wessel criteria)
- **epidemiology:** 10% of infants; usual onset 10 d to 3 mo of age with peak at 6-8 wk
- **etiology:** unknown. Theories: alterations in fecal microflora, cow's milk intolerance, GI immaturity or inflammation, poor feeding, maternal smoking
- diagnosis of exclusion after thorough history and physical exam to rule out identifiable causes such as otitis media, cow's milk intolerance, GI problem, fracture
- **management**
  - parental relief, rest, and reassurance
  - change breastfeeding or bottle-feeding technique
  - hold baby, soother, car ride, music, vacuum, check diaper
  - limited evidence for probiotics; further research required
  - maintain breastfeeding but eliminate allergens (cow's milk protein, eggs, wheat, and nuts) from mother's diet
  - prognosis: all resolve, most in the first 3-6 mo of life, no long-term adverse effects

Dentition and Caries

Dentition

- primary dentition (20 teeth)
  - first tooth at 5-9 mo (lower incisor), then 1/mo
  - 6-8 central teeth by 1 yr
  - assessment by dentist 6 mo after eruption of first tooth and certainly by 1 yr of age (Grade B recommendation)
- secondary dentition (32 teeth)
  - first adult tooth is 1st molar at 6 yr, then lower incisors

Caries

- early childhood caries: presence of one or more decayed, missing (due to caries), or filled tooth surfaces in any primary tooth in a preschool-aged child
- **etiology:** multifactorial with biomedical factors (e.g. diet, bacteria, host) and social determinants of health
  - inappropriate feeding practices (e.g. frequent, prolonged bottle feeding, putting to bed with bottle, prolonged breast feeding, and excessive juice consumption) are important factors
- prevention
  - no bottle at bedtime, clean teeth after last feed
  - minimize juice and sweetened pacifier
  - clean gums with damp washcloth or soft-bristle toothbrush (no toothpaste) when no teeth present
  - <3 yr: daily brushing with fluoridated toothpaste (size of a grain of rice) as soon as teeth are present
  - 3-6 yr: assisted to brush teeth using pea sized amount of fluoridated toothpaste
  - ensure every child visits dentist by 1 yr
  - 1 yr and beyond: involve dental public health programs (e.g. Healthy Smiles) to support access for children in low-income households

Enuresis

Definition

- involuntary urinary incontinence by day and/or night in child >5 yr

Treatment for primary nocturnal enuresis should not be considered until 7 yr due to high rate of spontaneous cure

General Approach

- should be evaluated if: dysuria; change in colour, odour, or stream; secondary or diurnal; change in gait; or stool incontinence are present

Primary Nocturnal Enuresis

- **clinical features:** enuresis when bladder control has never been attained
- **epidemiology:** 10% of children age 6, 3% of children age 12, 1% of children age 18, family history important
- **etiology:** developmental disorder or maturational lag in bladder control while asleep

- **management**
  - time, reassurance (~20% resolve spontaneously each yr), and avoidance of punishment or humiliation to maintain self-esteem
  - behaviour modification (limiting fluids and avoid caffeine-containing food before bedtime, void prior to sleep, ensure access to toilet, take out of diapers)
  - conditioning: "wet" alarm wakes child upon voiding (70% success rate)
  - medications (for children >7 yr, considered second line, short-term therapy, may be used for sleepovers/camp): desmopressin (DDAVP) oral tablets (similar success rate as "wet" alarm therapy but higher relapse rate), imipramine (Tofranil®) (rarely used; lethal if overdose; side effects: cardiac toxicity, anticholinergic effects)

Management and Treatment of Nocturnal Enuresis – An Updated Standardization Document from the International Children's Continence Society
J Pediatr Urol 2020;10-19
Additional investigations are not warranted in an enuretic child without certain warning signs. Key comorbidities to consider include psychiatric disorders, constipation, urinary tract infections and snoring or sleep apneas. Treating constipation and daytime incontinence can lead to symptom resolution. Treating concomitant sleep disorder may also lead to symptom resolution and is indicated. If enuresis is non-monosymptomatic, treatment should begin with advice on evening drinking and voiding habits. In monosymptomatic enuresis, treatment should begin with either desmopressin or an enuresis alarm. Second line treatment includes anticholinergic medications. Antidepressants may be considered in refractory enuresis though expert opinion should be sought.

Secondary Enuresis

- **clinical features:** enuresis develops after child has sustained period of bladder control (>6 mo)
- **etiology:** inorganic regression due to stress or anxiety (e.g. birth of sibling, significant loss, family discord, sexual abuse), secondary to organic disease (UTI, DM, DI, sleep apnea, neurogenic bladder, CP, seizures, pinworms)
- **management:** treat underlying cause, specialist referral as appropriate

Diurnal Enuresis

- **clinical features:** daytime wetting (60-80% also wet at night)
- **etiology:** micturition deferral (holding urine until last minute) due to psychosocial stressor (e.g. shy), structural anomalies (e.g. ectopic ureteral site, neurogenic bladder), UTI, constipation, CNS disorders, DM
- **management:** treat underlying cause, behavioural (scheduled toileting, double voiding, good bowel program, sitting backwards on toilet, charting/incentive system, relaxation/biofeedback), good constipation management, pharmacotherapy

Encopresis

- **clinical features:** fecal incontinence in a child >4 yr, at least once per mo for 3 mo
- prevalence: 1-1.5% of school-aged children (rare in adolescence); M:F=6:1 in school-aged children
- causes: chronic constipation (retentive encopresis), Hirschsprung disease, hypothyroidism, hypercalcemia, spinal cord lesions, CP, hypotonia, anorectal malformations, bowel obstruction

Retentive Encopresis

- **definition:** child holds bowel movement, develops constipation, leading to fecal impaction and seepage of soft or liquid stool (overflow incontinence)
- **etiology**
  - physical: painful stooling often secondary to constipation
  - emotional: disturbed parent-child relationship, coercive toilet training, social stressors
- **clinical features**
  - history
    - crosses legs or stands on toes to resist urge to defecate
    - distressed by symptoms, soiling of clothes
    - toilet training coercive or lacking in motivation
    - may show oppositional behaviour
    - abdominal pain
  - physical exam
    - digital rectal exam or abdominal x-ray: large fecal mass in rectal vault
    - anal fissures (result from passage of hard stools)
    - palpable stool in LLQ abdomen (50% of children with fecal incontinence)
    - staining of underwear with stool
- **management**
  - complete clean-out of bowel: PEG 3350 given orally is most effective and first line; enemas and suppositories may be second line therapies, but these are invasive, often less effective, and not recommended as first line
  - maintenance of regular bowel movements (see *Constipation*, P46)
  - assessment and guidance regarding psychosocial stressors
  - behavioural modification
- **complications:** recurrence, toxic megacolon (requires >3-12 mo to treat), bowel perforation

Toilet Training

- 90% of children attain bowel control before bladder control
- generally, females train earlier than males
- 25% by 2 yr (in North America), 98% by 3 yr have daytime bladder control
- signs of toilet readiness (usually 18-24 mo)
  - ambulating independently, stable on potty, desire to be independent or to please caregivers (i.e. motivation), sufficient expressive and receptive language skills (2-step command level), can stay dry for several hours (large enough bladder), can recognize need to go, able to remove clothing
- stepwise approach used to familiarize child with the potty chair and create a connection between elimination and the potty chair; praise with use of potty chair

Failure to Thrive

- **definition**
  - weight <3rd percentile, falls across two major percentile curves on growth chart, or <80% of expected weight for height and age
  - inadequate caloric intake most common factor in poor weight gain
  - may have other nutritional deficiencies (e.g. protein, iron, vitamin D)
  - factors affecting physical growth: genetics, intrauterine factors, nutrition, endocrine hormones, chronic infections/diseases, psychosocial factors
- **clinical features**
  - history
    - nutritional intake
    - current symptoms
    - past illnesses
    - family history: growth, puberty, parental height and weight (including mid-parental height)
    - psychosocial history
  - physical exam
    - growth parameters, plotted
    - <2 yr: height, weight, head circumference
    - ≥2 yr: height, weight, BMI
    - vital signs
    - complete head to toe exam
    - dysmorphic features or evidence of chronic disease
    - upper to lower segment ratio
    - sexual maturity staging
    - signs of maltreatment or neglect
- **investigations** (as indicated by clinical features)
  - CBC, blood smear, electrolytes, T_4, TSH, urea, ferritin, Ca^{2+}, celiac screen, and vitamins A, D, E
  - bone age x-ray
  - chromosomes/karyotype
  - chronic illness: chest (CXR, sweat Cl^-), cardiac (CXR, ECG, echo), GI (celiac screen, inflammatory markers, malabsorption), renal (urinalysis), liver (enzymes, albumin)

Table 12. Failure to Thrive Patterns

Growth Parameters			Suggestive Abnormality	
Decreased Wt	Normal Ht	Normal HC	Caloric insufficiency Decreased intake	Hypermetabolic state Increased losses
Decreased Wt	Decreased Ht	Normal HC	Structural dystrophies Endocrine disorder	Constitutional growth delay (BA < CA) Familial short stature (BA = CA)
Decreased Wt	Decreased Ht	Decreased HC	Intrauterine insult	Genetic abnormality

BA = bone age; CA = chronological age; HC = head circumference; Ht = height; Wt = weight

Etiology

- an interplay between pathophysiology and psychosocial influences
- investigations should assess:
  1. complex factors in the parent-child relationship
     - dietary intake, knowledge about feeding, improper mixing of formula
     - feeding environment
     - parent-child interaction, attachment
     - child behaviours, hunger/satiety cues
     - postpartum depression
     - social factors: stress, poverty, neglect, child/domestic abuse, parental substance abuse, restricted diets
  2. inadequate caloric intake: inadequate milk supply/latching, mechanical feeding difficulty (cleft palate), oromotor dysfunction, toxin-induced anorexia
  3. inadequate absorption: biliary atresia, celiac, IBD, CF, inborn errors of metabolism, milk protein allergy, pancreatic cholestatic conditions

Mid-Parental Height
- Boys target height = (father height + mother height + 13) / 2
- Girls target height = (father height + mother height – 13) / 2

Note: height should be taken in cm

Clinical Signs of FTT

SMALL KID
Subcutaneous fat loss
Muscle atrophy
Alopecia
Lethargy
Lagging behind normal
Kwashiorkor
Infection (recurrent)
Dermatitis

Upper to Lower Segment Ratio
- Increased in achondroplasia, short limb syndromes, hypothyroidism, storage diseases
- Decreased in Marfan's, Klinefelter's, Kallman's syndromes, and testosterone deficiency
- Calculation: upper segment/lower segment
- Upper segment: top of head to pubic symphysis
- Lower segment: pubic symphysis to floor

4. increased metabolism: chronic infection, CF, lung disease from prematurity, hyperthyroidism, asthma, IBD, malignancy, renal failure
5. increased losses
6. increased utilization (e.g. chromosomal disorders)
7. prenatal factors: placental insufficiency, intrauterine infections, genetic, maternal

Management

- most as outpatient using multidisciplinary approach: primary care physician, occupational therapist, dietitian, psychologist, social work, CAS
- medical: oromotor problems, iron deficiency anemia, gastroesophageal reflux
- nutritional: educate about age-appropriate foods, calorie boosting, mealtime schedules, and environment; goal to reach 90-110% IBW, correct nutritional deficiencies, and promote catch-up growth/development
- behavioural: positive reinforcement, mealtime environment, no distractions (e.g. toys, books, or TV) during mealtime

Energy Requirements

- see *Nutrition*, P8

Obesity

- **definition**

Age	Overweight	Obese
0-2 yr	Weight for length >97th percentile	Weight for length >99.9th percentile
2-5 yr	BMI >97th percentile	BMI >99.9th percentile
5-19 yr	BMI >85th percentile	BMI >97th percentile

- **risk factors:** genetic predisposition (e.g. both parents obese – 80% chance of obese child), psychosocial/environmental contributors
- **etiology**
  - increased intake (dietary, social/behavioural, and iatrogenic such as drugs and hormones)
  - decreased energy expenditure
  - organic causes are rare (<5%): neuroendocrine (e.g. hypothyroidism, Cushing, PCOS), genetic (e.g. Prader-Willi, Carpenter, Turner Syndromes)
- **complications:** association with HTN, dyslipidemia, slipped capital femoral epiphysis, T2DM, asthma, OSA, gynecomastia, polycystic ovarian disease, early menarche, irregular menses, psychological trauma (e.g. bullying, decreased self-esteem, unhealthy coping mechanisms, depression)
- childhood obesity often persists into adulthood
- investigations: BP, pulse, screen for: dyslipidemia, fatty liver disease (ALT), T2DM (based on risk factors)
- **management**
  - encouragement and reassurance; engagement of entire family
  - diet: qualitative changes (do not encourage weight loss, but allow for linear growth to catch up with weight), special diets used by adults and very low calorie diets are not encouraged
  - behaviour modification: increase activity, change eating habits/meal patterns, limit juice/sugary drinks, ensure adequate sleep
  - education: multidisciplinary approach, dietitian, counselling
  - surgery and pharmacotherapy are rarely used in children
  - increase physical activity (1 h/d), reduce screen time (<2 h/d)
  - small changes in energy expenditure and intake (lose 1 lb/mo)
  - long term goal: maintain BMI <85th percentile

Poison Prevention

- keep all types of medicines, vitamins, and chemicals locked up in a secure container, out of sight, and out of reach
- potentially dangerous: medications, illicit drugs, drain cleaners, furniture polish, insecticides, cosmetics, nail polish remover, automotive products
- do not store any chemicals in juice, soft drink, or water bottles
- keep alcoholic beverages out of reach: 3 oz hard liquor can kill a 2 yr old
- always read labels before administering medicine to ensure correct medication drug and dose and/or speak with a pharmacist or healthcare provider

Perinatal and Early Childhood Factors for Overweight and Obesity in Young Canadian Children
C J Public Health 2013;104(1):e69-74
Purpose: To assess potential early-life factors and their interrelationships with obesity among young Canadian children.
Methods: Data from a nationally representative sample of children ages 6-11 yr in the Canadian Health Measures Survey were analyzed. The associations of perinatal and early childhood behaviours and socioeconomic factors with overweight or obesity were evaluated using multivariate logistic regression models.
Results: Of 968 term-born children, 21% were overweight and another 13% were obese. Maternal smoking during pregnancy was positively associated with obesity. This association was mediated by birth weight and once controlled, the strength of the association between smoking and child obesity increased by 12%. Birth weight per 100 g (1.05; 1.005-1.09) was significantly associated with obesity. Exclusive breastfeeding for 6 mo, adequate sleep hours, and being physically active were found to be protective. Breastfeeding, whether exclusive or not, significantly reduced obesity risk among children whose mothers never smoked in pregnancy.
Conclusion: This study identified multiple perinatal and childhood factors associated with obesity in young Canadian children. Effective prevention strategies targeting four modifiable maternal and child risk factors may reduce childhood obesity by up to 54% in Canada.

Screen Time Guidelines (Canadian Society for Exercise Physiology)
- Screen time is not recommended for children under 2 yr
- <1 h/d screen time is appropriate for children 2-5 yr
- <2 h/d screen time is appropriate for children 5-17 yr

Rashes

Table 13. Common Paediatric Rashes

Type of Rash	Differential	Appearance	Management
Diaper Dermatitis	Irritant contact dermatitis	Shiny, red macules/patches, no skin fold involvement	Eliminate direct skin contact with urine and feces, allow periods of rest without a diaper, frequent diaper changes, topical barriers (petrolatum, zinc oxide or paste), short-term low-potency topical corticosteroids (severe cases)
	Seborrheic dermatitis	Yellow, greasy macules/plaques on erythema, scales	Short-term, moisturisers, topical antifungal (ketoconazole), low-potency topical corticosteroids
	Candidal dermatitis	Erythematous macerated papules/plaques, satellite lesions, involvement of skin folds	Antifungal agents (e.g. clotrimazole, nystatin)
Other Dermatitis	Atopic dermatitis	Erythematous, papules/plaques, oozing, excoriation, lichenification, classic areas of involvement	Eliminate exacerbating factors, maintain skin hydration (daily baths and moisturisers), corticosteroids, topical calcineurin inhibitor (2nd line)
	Nummular dermatitis	Annular erythematous plaques, oozing, crusting	Avoid irritant if identified, potent topical steroid in emollient base, short-term systemic steroids ± antibiotics (severe)
	Allergic contact dermatitis	Red papules/plaques/vesicles/bullae, only in area of allergen	Mild: soothing lotion (e.g. calamine lotion) Moderate: low-to-intermediate potency topical corticosteroids Severe: systemic corticosteroids and antihistamine
	Irritant contact dermatitis	Morphology depends on irritant	Avoid skin contact
	Dyshidrotic dermatitis	Papulovesicular, cracking/fissuring, hands and feet ("tapioca pudding")	Mild/moderate: medium/potent topical corticosteroids Severe: systemic corticosteroids, local PUVA or UVA treatments
Infectious	Scabies	Polymorphic (red excoriated papules/nodules, burrows), in web spaces/folds, very pruritic Often affects multiple family members	Permethrin (Nix®) 5% cream for patient and family (2 applications, 1 wk apart)
	Impetigo	Honey-coloured crusts or superficial bullae	Mild: topical antibiotics (e.g. fucidic acid or mupirocin cream) Severe: oral antibiotics (e.g. cephalexin/erythromycin)
	Tinea corporis	Round erythematous plaques, central clearing and scaly border	Topical antifungal for skin, systemic antifungals for nails/head
Paediatric Exanthems (see *Infectious Paediatric Exanthems*, P62)			
Acne (see Dermatology, D14)			
Neonatal skin conditions (see *Skin Conditions of the Neonate*, P82)			

Sleep Disturbances

Types of Sleep Disturbances

- BEARS screening tool
- insufficient sleep quantity
  - difficulty falling asleep (e.g. limit setting sleep disorder)
    - preschool and older children
    - bedtime resistance
    - due to caregiver's inability to set consistent bedtime rules and routines
    - often exacerbated by child's oppositional behaviours
- poor sleep quality
  - frequent arousals (e.g. sleep-onset association disorder)
    - infants and toddlers
    - child learns to fall asleep only under certain conditions or associations (e.g. with parent, held, rocked or fed, with light on, in front of television), and loses ability to self-soothe
    - during the normal brief arousal periods of sleep (q90-120 min), child cannot fall back asleep because same conditions are not present
- OSA
  - **definition:** partial or intermittent complete airway obstruction during sleep causing disrupted ventilation and sleep pattern
  - **diagnostic criteria**: 1+ of the following features – snoring, obstructed breathing, sleepiness/behavioural problems; evidence of either obstructive apneas or hypopneas, or pattern of obstructive hypoventilation

Daily Sleep Requirement	
<6 mo	16 h
6 mo	14.5 h
12 mo	13.5 h
2 yr	13 h
4 yr	11.5 h
6 yr	9.5 h
12 yr	8.5 h
18 yr	8 h
Nap Patterns	
2/d at 1 yr	
1/d at 2 yr (2-3 h long)	
0.5/d at 5 yr (1.7 h long)	

  - **epidemiology:** 1-5% of preschool aged children, more common in Black children
  - **clinical features:** snoring/gasping/noisy breathing during sleep and irritable/tired/hyperactive during the day
  - **complications:** cardiovascular (HTN/LV remodelling due to sympathetic activation), growth, cognitive, and behavioural problems
  - **etiology:** adenotonsillar hypertrophy, craniofacial abnormalities, obesity
  - investigations: polysomnography is gold standard for diagnosis but not required (expensive, inaccessible)
  - **management:** adenotonsillectomy and weight management are first-line tx, follow-up for residual OSA. Watchful waiting acceptable in mild-moderate cases
    - adenotonsillectomy does not improve executive function/attention but improves behaviour, QOL, polysomnographic findings
    - use CPAP if adenotonsillectomy is contraindicated (cleft palate/bleeding disorder/acute tonsillitis), OSA w/ minimal adenotonsillar tissue, residual OSA
    - avoid pollutants/tobacco smoke, allergens
    - avoid use of corticosteroids and antibiotics
- parasomnias
  - episodic nocturnal behaviours (e.g. sleepwalking, sleep terrors, nightmares)
  - often involves cognitive disorientation and autonomic/skeletal muscle disturbance

Management of Sleep Disturbances
- set strict bedtimes and "wind-down" routines
- do not send child to bed hungry
- positive reinforcement for: limit setting sleep disorder
- always sleep in own bed, in a dark, quiet, and comfortable room
- avoid screens before bedtime and avoid caffeine-containing food
- do not use bedroom for timeouts
- systematic ignoring and gradual extinction for: sleep-onset association disorder

Nightmares
- **epidemiology:** common in boys, 4-7 yr
- associated with REM sleep (generally last one third of sleep)
- **clinical features:** upon awakening, child is alert and clearly recalls frightening dream ± associated with daytime stress/anxiety
- **management:** reassurance

Night Terrors
- **epidemiology:** 15% of children have occasional episodes
- usually in first one third of night; arousal from deep (slow wave) sleep
- **clinical features:** abrupt sitting up, eyes open, screaming/vocalization, occurs in early hours of sleep, stage 4 of sleep; signs of autonomic arousal with no memory of event, disoriented if awakened, inconsolable, stress/anxiety can aggravate them
- **management:** reassurance from parents, ensure child is safe (e.g. if sleepwalks), parents can try to identify pattern and wake up child 15 min before to disrupt pattern, often remits spontaneously before puberty

Sudden Infant Death Syndrome

Definition
- sudden and unexpected death of an infant <12 mo in which the cause of death cannot be found by history, examination, or a thorough postmortem and death scene investigation

Epidemiology
- 0.5 in 1000 (leading cause of death between 1-12 mo); M:F=3:2
- more common in children placed in prone position
- in full term infants, peak incidence is 2-4 mo, 95% of cases occur by 6 mo
- increase in deaths during peak RSV season
- most deaths occur between midnight and 8 AM

Risk Factors
- prematurity (<37 wk), early bed sharing (<12 wk), alcohol use during pregnancy, soft bedding, low birthweight, Indigenous background, male, no prenatal care, smoking in household, prone sleep position, poverty
- risk of SIDS is increased 5-6x in siblings of infants who have died of SIDS
- bed sharing: sleeping on a sofa, adult sleeping with an infant after consumption of alcohol/street drugs or extreme fatigue, sleeping on a surface with a fixed wall (couch/sofa), infant sleeping with someone other than primary caregiver

Brief Resolved Unexplained Events (BRUE)
These are sudden, brief (<1 min) and now resolved episodes in an infant with one or more of the following: cyanosis or pallor; absent, decreased or irregular breathing; change in tone; and/or altered level of consciousness. The observer fears the child may be dying. The child should be asymptomatic on presentation and there is no explanation after a history and physical for the cause. There is no clear connection between most BRUEs and SIDS. Evaluating for a cause of the BRUE (e.g. infection, cardiac, neurologic, child abuse, metabolic disease, toxins, etc.) is guided by history, physical exam, and period of observation. Etiology: inherently unknown, but affected infants appear to have (1) underlying genetic or anatomic (e.g., brainstem abnormality) predisposition and (2) a trigger event (e.g. maternal smoking, airflow obstruction). A BRUE appears to happen when (1) and (2) occur during a vulnerable stage of development

Prevention
- "Back to Sleep, Front to Play" (place infant on back when sleeping, daily supervised play/"tummy time" in prone position)
- avoid sharing bed with infant
- avoid tobacco smoke exposure
- avoid overheating and overdressing
- appropriate infant bedding (firm mattress, avoid loose bedding, pillows, stuffed animals, and crib bumper pads)
- exclusive breastfeeding in first mo and no smoking
- pacifiers appear to have a protective effect; do not reinsert if falls out during sleep
- infant monitors do not reduce incidence

Adolescent Medicine

Adolescent History (HEEADSSS)
- review confidentiality and its limits with adolescent prior to taking history
- tailor your history according to the clinical context

Home: Who do you live with? What kind of place do you live in? Do you get along with your parents and/or siblings? Is your home a safe place for you?

Education/Employment: What grade are you in? What are your favourite subjects? Tell me about your grades. How often do you miss school/class? Do you work (if so, how much)? Do you get along with teachers/employers?

Eating: Tell me about your meals/snacks in a typical day. Have you ever gone on a diet? What are your favourite and least favourite foods? (see Psychiatry, *Eating Disorders*, PS39)

Activities: What do you do after school? On the weekends? How much time do you spend on the computer/watching TV every day? Do you use social media (i.e. Facebook, Twitter, Instagram, etc.)? What do you do with your friends outside of school?

Drugs: Which seems to be more popular at your school, alcohol or drugs? How often do you drink/smoke cannabis or cigarettes/take other drugs? Have you ever passed out or not been able to remember what happened? Has anything bad ever happened to you while you were drunk or stoned?
- can organize as a CRAFFT screen Ask Part A, questions 1-3. If yes to any, then ask 6 CRAFFT questions. If no, then move on to Part B, question 1
  - Part A: during the last 12 mo, did you:
    1. Drink any alcohol?
    2. Smoke any cannabis, vape, or inhale any other substance?
    3. Use anything else to get high?
  - Part B:
    1. Have you ever ridden in a car driven by someone (including yourself) who was high or had been using drugs/alcohol?
    2. Do you ever use drugs/alcohol to relax, feel better about yourself, or fit in?
    3. Do you ever use drugs/alcohol when you are alone?
    4. Do you ever forget things you did while using drugs/alcohol?
    5. Do your family/friends ever tell you that you should cut down on your drinking or drug use?
    6. Have you ever gotten into trouble while you were using drugs/alcohol?
- see Psychiatry, *Substance-Related and Addictive Disorders*, PS26

Sexuality: What are your preferred pronouns? Do you have a crush on anyone? Do you have a partner? What does 'sex' mean to you? Have you ever had sex? Whether the answer is yes or no, the next question is: What activities would you include in the term 'having sex'? What do you do to prevent getting a STI/getting pregnant/getting someone pregnant? Has anyone ever given you money, drugs, or other stuff in exchange for sex? (see Gynaecology, *Sexually Transmitted Infections*, GY28)

Suicidality/Depression: How would you describe your mood most days? On a scale of 1 to 10, where 1 is so sad that you might kill yourself and 10 is the happiest you could be, where are you most days? Have you lost interest in activities that you used to enjoy? Do you often have trouble sleeping (Is there a difference between school days and the weekend?)? Have you ever thought seriously about suicide? Did you make a plan? (see Psychiatry, *Depression/Suicide*, PS12, PS5)

Safety/Violence: Do you ever get into a car with a driver who has been drinking or taking drugs? Do you always wear a seatbelt/bicycle helmet? Are you being bullied at school? Has anyone ever touched you in an unwanted way?

See *Disorders of Sexual Development*, P35

Adolescent Psychosocial Assessment

HEEADSSS
Home
Education/Employment
Eating

Sexuality
Suicide and depression
Safety/violence

Past year drug use (%) in Ontario adolescents (2019): alcohol (41.7%), cannabis (22.0%), tobacco cigarettes (5.0%), electronic cigarettes (22.7%)

CRAFFT Screen
The CRAFFT is a well-validated substance use screening tool for adolescents 12-21 yr. See the CRAFFT website: crafft.org

Consent and Close Age Exceptions
- The age of consent is 16
- A youth 16 or 17 y/o cannot consent if: the partner is in a position of trust/authority (e.g. coach, teacher), young person is dependent on the partner (e.g. for care or support), the relationship is exploitative (e.g. prostitution or pornography)
- A 14 or 15-y/o can consent as long as the partner is less than 5 years older and as long as there is no relationship of trust, authority, dependency, or exploitation
- A 12 or 13-y/o can consent as long as the partner is less than 2 years older and as long as there is no relationship of trust, authority, dependency, or exploitation

Half of police-reported sexual offences are against children and youth

4.9% of Canadian youth (age 12-17) have a mood disorder

Table 14. Developmental Stages of Adolescence

	Early Adolescence (10-13 yr)	Middle Adolescence (14-16 yr)	Late Adolescence (17-19 yr)
Cognitive and Moral	Concrete Unable to perceive long-term outcome of current decision-making	Emergence of abstract thought Questioning more	Future oriented with sense of perspective Idealism Ability to think things through independently
Self-Concept/Identity Formation	Preoccupied with changing body Self-consciousness about appearance and attractiveness	Concern with attractiveness "Stereotypical adolescent"	More stable body image Attractiveness may still be of concern Firmer identity
Family	Increased need for privacy	Conflicts over control and independence Struggle for acceptance of greater autonomy	Emotional and physical separation from family Increased autonomy
Peers	Seeks same-sex peer affiliation to counter instability	Intense peer group involvement	Peer group and values recede in importance Intimacy/possible commitment takes precedence
Sexual	Preoccupation with peers	Testing ability to attract partner Initiation of relationships and sexual activity Questions of sexual orientation	Consolidation of sexual identity Focus on intimacy and formation of stable relationships

Child Abuse and Neglect

Definition
- an act of commission (physical, sexual, or psychological abuse) or omission (neglect) by a caregiver that results in harm to a child or potential for harm

Legal Duty to Report
- upon reasonable grounds to suspect abuse and/or neglect, physicians are required by legislation to contact the CAS to personally disclose all information relevant to the child's safety concern
- duty to report overrides patient confidentiality; physician is protected against liability

Ongoing Duty to Report
- if there are additional reasonable grounds to suspect abuse and/or neglect, a further report to the CAS must be made

Risk Factors
- environmental factors: social isolation, poverty, domestic violence
- caregiver factors: personal history of abuse, psychiatric illness, postpartum depression, substance abuse, single parent family, poor social and vocational skills, below average intelligence
- child factors: difficult temperament, disability, special needs (e.g. developmental delay), premature

Management of Physical Abuse, Child Abuse, and Neglect
- do not take an abuse history from a young child; this must be done by trained personnel (e.g. during a forensic interview)
- report all suspicions to CAS; request emergency visit if imminent risk to child or any siblings in the home
- acute medical care: hospitalize for medical evaluation or treatment of injuries if indicated
- arrange consultation from social work and appropriate follow-up

Physical Abuse

History
- history that is not compatible with physical findings or with child's developmental capabilities
- history not reproducible or changes dramatically over time
- delay in seeking medical attention that is unexplained by other factors
- assess previous trauma or hospitalizations
- ask FHx: bleeding disorder, bone disorder, metabolic conditions
- ask developmental history

Physical Exam
- physical findings not explained by underlying medical condition
- growth parameters including past recorded parameters (weight, height, head circumference)
- multiple injuries not explained by accidental injury or child's development level
- patterned skin injuries: linear, shapes, etc. that do not match provided history

- injury location:
  - bruises: on areas with abundant soft-tissue cushioning, such as abdomen, buttocks, genitalia, fleshy part of cheek or on ears, neck or feet, bruises that do not fit described cause
  - fractures: posterior rib/metaphyseal/scapular/vertebral/sternal fractures
  - immersion burns (e.g. hot water)
- altered mental status: head injury, poisoning
- eyes – retinal hemorrhages
- scalp – patchy hair loss from traumatic alopecia or severe malnutrition
- oral exam – check the frenula for tears
- head trauma is the leading cause of death in child maltreatment (e.g. acceleration-deceleration forces (shaking), direct force application (blow or impact))
- consider "red herrings" (e.g. slate grey macule/congenital dermal melanocytosis vs. bruises)

Investigations
- document all injuries on a body diagram: type, location, size, shape, colour, pattern
  - photography of skin injuries is ideal (police or hospital photography preferred; do not use physician's personal camera)
- rule out medical causes of bruising/fracture with appropriate investigations (e.g. blood disorders or rickets):
  - if fractures evident: Ca^{2+}, Mg^{2+}, PO_4^{3-}, ALP, PTH, Vitamin D, albumin
  - if bruising present: CBC, INR, PTT, von Willebrand factor, factors VIII/IX
- screen for abdominal trauma
  - transaminases and amylase if elevated: abdominal CT recommended
  - renal function – electrolytes, urinalysis
    - toxicology screen – overdose or poisoning
- skeletal survey in children <2 yr; select imaging based on history in children >5 yr
  - neuroimaging: CT and/or MRI - dilated eye examination by paediatric ophthalmologist to rule out retinal hemorrhage if subdural hemorrhage detected on head imaging

Sexual Abuse

Epidemiology
- peak at 2-6 yr and 12-16 yr, most do not report until adulthood
- as adults: more likely to develop obesity, sexual problems, IBS, fibromyalgia, STI, substance use disorder
- more likely to experience intimate partner violence and sexual assault
  - in decreasing order: family member, non-relative known to victim, stranger

History
- psychosocial: specific or generalized fears, depression, nightmares, social withdrawal, lack of trust, low self-esteem, school failure, sexually aggressive behaviour, advanced sexual knowledge, sexual preoccupation or play

Physical Exam
- recurrent UTIs, pregnancy, STIs, vaginitis, vaginal bleeding, pain, genital injury, enuresis
  - anogenital exam performed along with head-to-toe physical for physical trauma
  - instrumentation not required for anogenital exam, speculum contraindicated in prepubertal girls
  - most victims have normal anogenital exam – cannot rule out sexual abuse if exam is negative

Investigations
- depend on presentation, age, sex, and pubertal development of child
  - sexual assault examination kit within 24 h if prepubertal, within 72 h if pubertal
  - rule out STI, UTI, pregnancy (consider STI prophylaxis or emergency contraception)
  - rule out other injuries (vaginal/anal/oral penetration, fractures, head trauma)
  - rule out drug and alcohol screen (e.g. Rohypnol, 'Liquid G,' etc.)

Medical Assessment of Bruising in Suspected Child Maltreatment Cases
Paediatr Child Health 2013;18(8):433-437
CPS Position Statement: While bruises are most often due to minor accidental injury, they may also signal underlying medical illness or inflicted injury. Knowing when to assess bruises in the context of maltreatment can be challenging. The following are red flags for inflicted injury in such bruising cases:
- Babies not yet cruising
- Present on ears, neck, feet, buttocks or torso
- Not on the front of the body and/or overlying bone
- Unusually large or numerous
- Clustered or patterned
- Not fitting with the described causal mechanism

Neglect

Definition
- omissions in care by parents or caregiver that leads to actual or potential harm

History
- from child and each caregiver separately (if possible)

Physical Exam
- head to toe (do not force), growth parameters, nutrition status
- dental care
- emotional state

Presentation of Neglect
- FTT, developmental delay
- Inadequate or dirty clothing, poor hygiene
- Child exhibits poor attachment to parents, no stranger anxiety

Investigations
- blood tests to rule out medical conditions or nutritional deficiencies (e.g. thrombocytopenia or coagulopathy)

Cardiology

Congenital Heart Disease

PRENATAL CIRCULATION

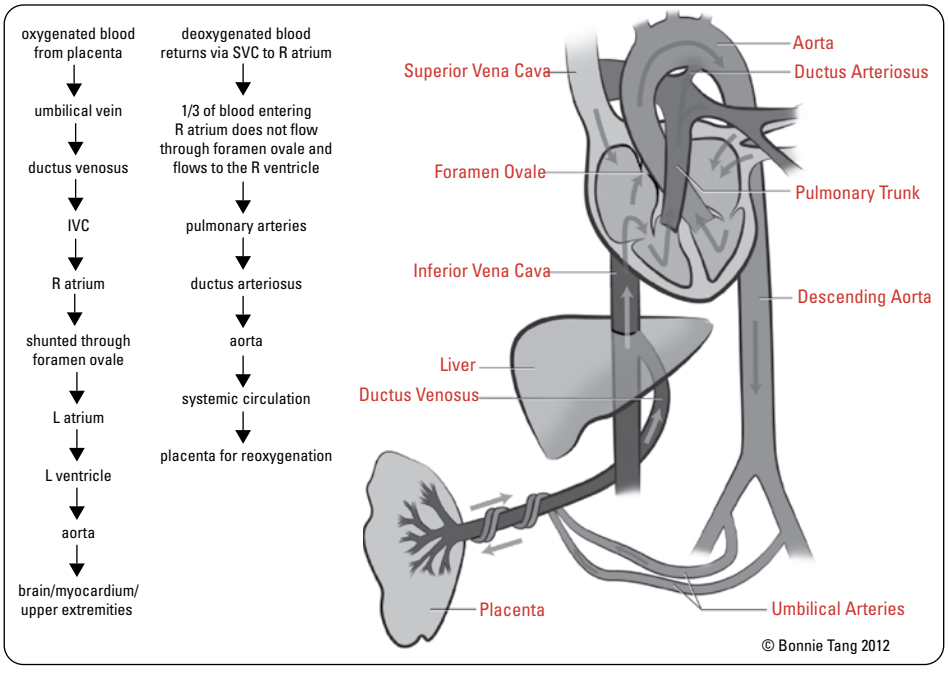

Figure 1. Prenatal circulation

Fetal circulation is designed so that oxygenated blood is preferentially delivered to the brain and myocardium

Before Birth
- shunting deoxygenated blood
  - ductus arteriosus: connection between pulmonary artery and aorta
- shunting oxygenated blood
  - foramen ovale: connection between right and left atria
  - ductus venosus: connection between umbilical vein and inferior vena cava

At Birth
- with first breath, lungs open up ➔ pulmonary resistance decreases ➔ pulmonic blood flow increases
- separation of low resistance placenta ➔ systemic circulation becomes a high resistance system ➔ ductus venosus closure
- increased pulmonic flow ➔ increased left atrial pressures ➔ foramen ovale closure
- increased oxygen concentration in blood after first breath ➔ decreased prostaglandins ➔ ductus arteriosus closure
- closure of fetal shunts and changes in vascular resistance ➔ infant circulation assumes normal adult flow

Epidemiology
- 8 in 1000 live births have CHD, which may present as a heart murmur, heart failure, or cyanosis; VSD is the most common lesion

Investigations
- echo, ECG, CXR
- pre- and postductal oxygen saturations, 4 limb BPs, hyperoxia test

CYANOTIC VS. ACYANOTIC CONGENITAL HEART DISEASE

- cyanosis: blue mucous membranes, nail beds, and skin secondary to an absolute concentration of deoxygenated hemoglobin of at least 30 g/dL
- acyanotic heart disease (i.e. L to R shunt, obstruction occurring beyond lungs): blood passes through pulmonic circulation ➔ oxygenation takes place ➔ low levels of deoxygenated blood in systemic circulation ➔ no cyanosis
- cyanotic heart disease (i.e. R to L shunt): blood bypasses the lungs ➔ no oxygenation occurs ➔ high levels of deoxygenated hemoglobin enters the systemic circulation ➔ cyanosis

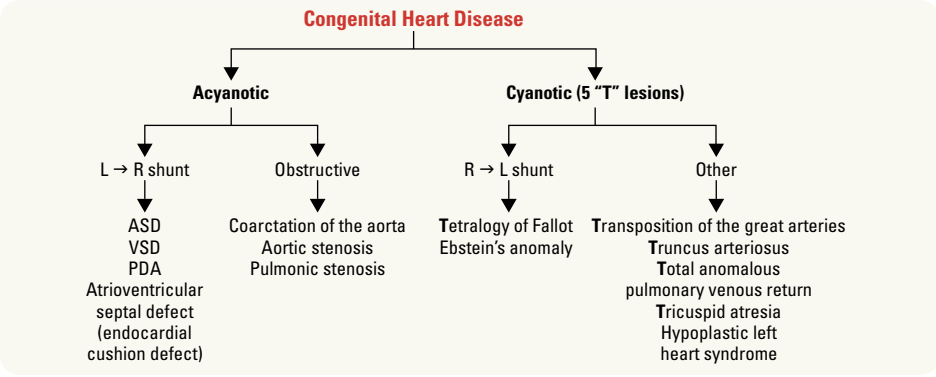

Figure 2. Common congenital heart diseases

Characteristic CXR Findings in CHD
- Boot-shaped heart: tetralogy of Fallot, tricuspid atresia
- Egg-shaped heart: transposition of great arteries
- "Snowman" heart: total anomalous pulmonary venous return

Acyanotic Congenital Heart Disease

1. LEFT-TO-RIGHT SHUNT LESIONS

- extra blood is displaced through a communication from the left to the right side of the heart ➔ increased pulmonary blood flow ➔ increased pulmonary pressures
- shunt volume is dependent upon three factors: (1) size of defect, (2) pressure gradient between chambers or vessels, and (3) peripheral outflow resistance
- untreated shunts can result in pulmonary vascular disease, left ventricular dilatation and dysfunction, right ventricular HTN and RVH, and ultimately R to L shunts

Atrial Septal Defect

- 3 types: *ostium primum* (common in DS, defect located at mitral or tricuspid valves), *ostium secundum* (most common type, 50-70%, defect located at septum between left and right atria), *sinus venosus* (defect located at entry of superior vena cava into right atrium)
- **epidemiology:** 6-8% of congenital heart lesions, common in patients with certain congenital disorders (e.g. DS, FAS)
- **natural history**
  - 80-100% spontaneous closure rate if ASD diameter <8 mm
  - if remains patent, CHF and pulmonary HTN can develop in adult life
- **clinical features**
  - history: often asymptomatic in childhood
  - physical exam: grade 2-3/6 pulmonic outflow murmur, widely split, and fixed S2
  - children with large ASDs may have signs of heart failure (tachypnea, FTT, hepatomegaly, pulmonary rales/retractions)
- **investigations**
  - ECG: RAD, mild RVH, RBBB (normal ECG does not rule out)
  - CXR: increased pulmonary vasculature, cardiac enlargement (normal ECG does not rule out)
  - echo: diagnostic
- **management**
  - elective surgical or catheter closure between 2-5 yr, though majority require no surgery
  - size <8 mm will likely spontaneously close

Ventricular Septal Defect

- most common congenital heart defect (30-50%)
- small VSD (majority)
  - **clinical features**
    - history: asymptomatic, normal growth, and development
    - physical exam: early systolic to holosystolic murmur, best heard at LLSB, thrill
  - **investigations**: echo to confirm diagnosis (ECG and CXR are normal)
  - **management:** most close spontaneously
- moderate-to-large VSD
  - **epidemiology:** CHF by 2 mo; late secondary pulmonary HTN if left untreated

Moderate-to-Large VSD
Size of VSD is inversely related to sound of murmur (loud murmur = smaller hole)

- **clinical features**
  - history: delayed growth, decreased exercise tolerance, recurrent URTIs or "asthma" episodes
  - physical exam: holosystolic murmur at LLSB, mid-diastolic rumble at apex, size of VSD is inversely related to intensity of murmur, loss of splitting of second heart sound and a loud P2 suggests pulmonary hypertension
- **investigations**
  - ECG: LVH, LAH, RVH (normal ECG does not rule out)
  - CXR: increased pulmonary vasculature, cardiomegaly, CHF (normal CXR does not rule out)
  - echo: diagnostic
- **management:** treatment of CHF and surgical closure by 1 yr, if surgery required

Patent Ductus Arteriosus

- patent vessel between descending aorta and left pulmonary artery (normally, functional closure within first 15 h of life, anatomical closure within first days of life)
- **epidemiology**
  - 5-10% of all congenital heart defects
  - delayed closure of ductus is common in premature infants (1/3 of infants <1750 g); this is different from PDA in term infants
- **natural history**: spontaneous closure common in premature infants, less common in term infants
- **clinical features**
  - history: asymptomatic, or have apneic or bradycardic spells, poor feeding, accessory muscle use, CHF
  - physical exam: tachycardia ± gallop rhythm, bounding pulses, hyperactive precordium, wide pulse pressure, continuous "machinery" murmur best heard at left infraclavicular area
- **investigations**
  - ECG: may show left atrial enlargement, LVH, RVH
  - echo is diagnostic
  - CXR: may show normal to mildly enlarged heart, increased pulmonary vasculature, prominent pulmonary artery
- **management**
  - indomethacin (Indocid®): antagonizes prostaglandin E2, which maintains ductus arteriosus patency; only effective in premature infants
  - catheter or surgical closure if PDA causes respiratory compromise, FTT, or persists beyond 3rd mo of life

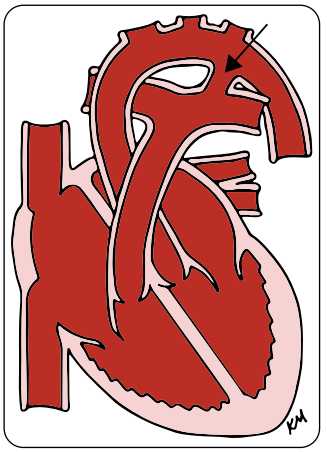

Figure 3. Patent duct arteriosus

2. OBSTRUCTIVE LESIONS

- present with decreased urine output, pallor, cool extremities and poor pulses, shock, or sudden collapse

Coarctation of the Aorta

- **definition:** narrowing of aorta (almost always at the level of the ductus arteriosus)
- **epidemiology:** commonly associated with bicuspid aortic valve (50%); Turner syndrome (35%)
- **clinical features**
  - history: often asymptomatic
  - physical exam
    - blood pressure discrepancy between upper and lower extremities (increased suspicion/severity if >20 mmHg difference)
    - diminished or delayed femoral pulses relative to brachial pulses (i.e. brachial-femoral delay)
    - possible systolic murmur with late peak at apex, left axilla, and left back
    - if severe, presents with shock in the neonatal period when the ductus arteriosus closes
- **investigations**: ECG shows RVH early in infancy, LVH later in childhood; echo or MRI for diagnosis
- **prognosis**: can be complicated by HTN; if associated with other lesions (e.g. PDA, VSD) can lead to CHF
- **management:** give prostaglandins to keep ductus arteriosus patent for stabilization and perform surgical correction in neonates; for older infants and children balloon arterioplasty may be an alternative to surgical correction

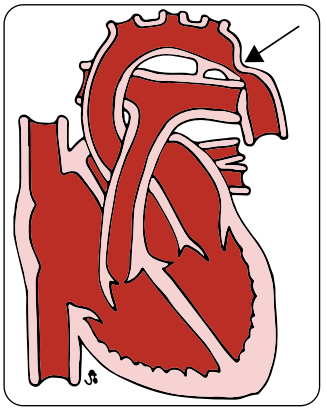

Figure 4. Coarctation of the aorta

Aortic Stenosis

- 4 types: valvular (75%), subvalvular (20%), supravalvular, and idiopathic hypertrophic subaortic stenosis (5%)
- **clinical features**
  - history: often asymptomatic, but may be associated with CHF, exertional chest pain, syncope, or sudden death
  - physical exam: SEM at RUSB with aortic ejection click at the apex (only for valvular stenosis)
- **investigations:** echo for diagnosis
- **management:** valvular stenosis is usually treated with balloon valvuloplasty, patients with subvalvular or supravalvular stenosis require surgical repair, exercise restriction required

Pulmonary Stenosis

- 3 types: valvular (90%), subvalvular, or supravalvular
- **definition of critical pulmonary stenosis**: inadequate pulmonary blood flow, dependent on ductus arteriosus for oxygenation, progressive hypoxia and cyanosis
- **natural history**: may be part of other congenital heart lesions (e.g. Tetralogy of Fallot) or in association with syndromes (e.g. congenital rubella, Noonan syndrome)
- **clinical features**
  - history: spectrum from asymptomatic to CHF
  - physical exam: wide split S2 on expiration, SEM at LUSB, pulmonary ejection click (for valvular lesions)
- **investigations**
  - ECG findings: RVH
  - CXR: post-stenotic dilation of the main pulmonary artery (due to high velocity jet past stenotic valve)
  - echo: diagnostic
- **management:** surgical repair if critically ill or if symptomatic in older infants/children

Cyanotic Congenital Heart Disease

- systemic venous return re-enters systemic circulation directly
- most prominent feature is cyanosis (O_2 saturation <75%)
- hyperoxic test differentiates between cardiac and other causes of cyanosis
  - obtain preductal, right radial ABG in room air, then repeat after the child inspires 100% O_2
  - if PaO_2 improves to >150 mmHg, cyanosis less likely cardiac in origin
- pre-ductal and post-ductal pulse oximetry
  - >5% difference suggests R to L shunt

Causes of Cyanotic Heart Disease – 5Ts

Truncus arteriosus
Transposition of the great vessels
Tricuspid atresia
Tetralogy of Fallot
Total anomalous pulmonary venous return

1. RIGHT-TO-LEFT SHUNT LESIONS

Tetralogy of Fallot

- **epidemiology:** 10% of all CHD, most common cyanotic heart defect diagnosed beyond infancy with peak incidence at 2-4 mo
- **pathophysiology**
  - embryological defect due to anterior and superior deviation of the outlet septum leading to: VSD, RVOTO (i.e. pulmonary stenosis ± subpulmonary valve stenosis), overriding aorta, and RVH
    - infants may initially have a L ➔ R shunt (therefore no cyanosis); however, RVOTO is progressive, leading to increasing R ➔ L shunting with hypoxemia and cyanosis
    - degree of RVOTO determines the direction and degree of shunt and, therefore, the extent of clinical cyanosis and degree of RVH
- **clinical features**
  - history: hypoxic "tet" spells
    - during exertional states (crying, exercise) the increasing pulmonary vascular resistance and decrease in systemic resistance causes an increase in right-to-left shunting
    - clinical features include paroxysms of rapid and deep breathing, irritability and crying, increasing cyanosis, decreased intensity of murmur (decreased flow across RVOTO), patient squatting for relief (increased peripheral resistance, decreased R to L shunting)
    - if severe, can lead to decreased level of consciousness, seizures, death
  - physical exam
    - single loud S2 due to severe pulmonary stenosis (i.e. RVOTO), SEM at LLSB
- **investigations**
  - ECG: RAD, RVH
  - CXR: boot-shaped heart, decreased pulmonary vasculature, right aortic arch (in 25%)
  - echo: diagnostic
- **management of spells**: O_2, knee-chest position, fluid bolus, morphine sulfate, propranolol, phenylephrine
- **treatment**: surgical repair at 4-6 mo of age; earlier if marked cyanosis or "tet" spells

Tetralogy of Fallot
1. VSD
2. RVOTO
3. Aortic root "overriding" VSD
4. RVH

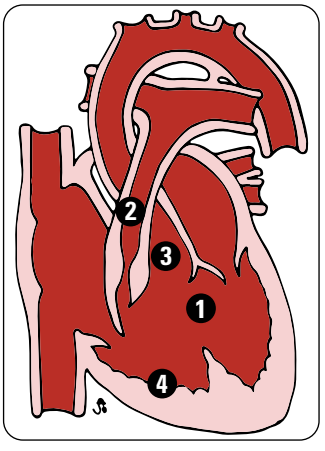

Figure 5. Tetralogy of Fallot

2. OTHER CYANOTIC CONGENITAL HEART DISEASES

Transposition of the Great Arteries

- **epidemiology:** 3-5% of all congenital cardiac lesions, most common cyanotic CHD in neonates
- **pathophysiology**: parallel pulmonary and systemic circulations
  - systemic: body ➔ RA ➔ RV ➔ aorta ➔ body
  - pulmonary: lungs ➔ LA ➔ LV ➔ pulmonary artery ➔ lungs
  - survival is dependent on mixing through PDA, ASD, or VSD
- **physical exam**
  - neonates: ductus arteriosus closure causes rapidly progressive severe hypoxemia unresponsive to oxygen therapy, acidosis, and death
  - VSD present: cyanosis is not prominent; CHF within first weeks of life
  - VSD absent: no murmur

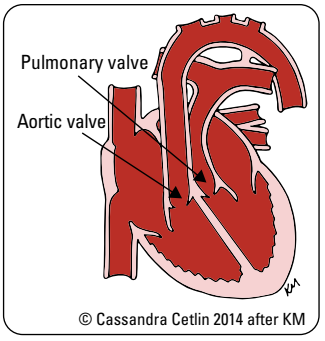

Figure 6. Transposition of the great arteries

- **investigations**
  - ECG: RAD, RVH, or may be normal
  - CXR: egg-shaped heart with narrow mediastinum ("egg on a string")
  - echo: diagnostic
- **management**
  - symptomatic neonates: prostaglandin E1 infusion to keep ductus open until balloon atrial septostomy
  - surgical repair: arterial switch performed in the first 2 wk in those without a VSD while LV muscle is still strong

Total Anomalous Pulmonary Venous Return
- **epidemiology:** 1-2% of CHD
- **pathophysiology**
  - all pulmonary veins drain into right-sided circulation (systemic veins, RA)
  - no direct oxygenated pulmonary venous return to left atrium
  - often associated with obstruction at connection sites
  - ASD must be present for oxygenated blood to shunt into the LA and systemic circulation
- **management:** surgical repair in all cases and required urgently for severe cyanosis

Truncus Arteriosus
- **pathophysiology**
  - single great vessel gives rise to the aorta, pulmonary, and coronary arteries
  - truncal valve overlies a large VSD
  - potential for coronary ischemia with fall in pulmonary vascular resistance
- **management:** surgical repair within first 6 wk of life

Hypoplastic Left Heart Syndrome
- **epidemiology:** 1-3% of CHD; most common cause of death from CHD in first mo of life
- **pathophysiology**: LV hypoplasia may include atretic or stenotic mitral and/or aortic valve, small ascending aorta, and coarctation of the aorta with resultant systemic hypoperfusion
- systemic circulation is dependent on ductus patency; upon closure of the ductus, infant presents with circulatory shock and metabolic acidosis
- **management**
  - intubate and correct metabolic acidosis
  - IV infusion of prostaglandin E1 to keep ductus open
  - surgical palliation (overall survival 50% to late childhood) or heart transplant

Ebstein's Anomaly
- Septal and posterior leaflets of tricuspid valve are malformed and displaced into the RV
- Potential for RV dysfunction, tricuspid stenosis, tricuspid regurgitation, or functional pulmonary atresia if RV unable to open pulmonic valves
- Accessory conduction pathways (e.g. WPW) are often present

Etiology
- Unknown, heterogeneous genetic predisposition, associated with maternal lithium and benzodiazepine use in 1st trimester

Treatment
- Newborns: consider closure of tricuspid valve + aortopulmonary shunt, or transplantation
- Older children: tricuspid valve repair or valve replacement + ASD closure

4 Features of Hypoplastic Left Heart Syndrome
- Hypoplastic LV
- Narrow mitral/aortic valves
- Small ascending aorta
- Coarctation of the aorta

Congestive Heart Failure

- see Cardiology and Cardiac Surgery, C40

Etiology
- CHD
- cardiomyopathy (primary or secondary)
- high output circulatory states (e.g. anemia, AVMs, cor pulmonale, hyperthyroidism)
- non-cardiac (e.g. sepsis, renal failure)
- pressure overload (e.g. aortic stenosis/coarctation, pulmonary stenosis, HTN)
- volume overload (e.g. L to R shunt, valve insufficiency)

Clinical Features
- infant: weak cry, irritability, feeding difficulties, early fatigability, diaphoresis while sleeping or eating, respiratory distress, lethargy, FTT
- child: decreased exercise tolerance, fatigue, decreased appetite, respiratory distress, frequent URTIs or "asthma" episodes
- orthopnea, paroxysmal nocturnal dyspnea, pedal/dependent edema are all uncommon in children
- physical findings: 4 key features (tachycardia, tachypnea, cardiomegaly, hepatomegaly). Additionally, FTT, alterations in peripheral pulses, four limb blood pressures (in some CHDs), dysmorphic features associated with congenital syndromes, gallop rhythm

Investigations
- CXR: cardiomegaly, pulmonary venous congestion
- ECG: sinus tachycardia, signs of underlying cause (heart block, atrial enlargement, hypertrophy, ischemia/infarct)
- echo: structural and functional assessment
- blood work: CBC, electrolytes, BUN, Cr, LFTs

Management
- general: sitting up, O_2, sodium and water restriction, increased caloric intake
- pharmacologic: diuretics, afterload reduction (e.g. ACEI), β-blockers; digoxin rarely used
- curative: correction of underlying cause

4 Key Features of CHF

2 Tachys and 2 Megalys
- Tachycardia
- Tachypnea
- Cardiomegaly
- Hepatomegaly

Dysrhythmias

- can be transient or permanent, congenital (structurally normal or abnormal), or acquired (toxin, infection, infarction)

Sinus Arrhythmia
- phasic variations with respiration (present in almost all normal children)

Sinus Tachycardia
- rate of impulses arising from sinus node is elevated (>150 bpm in infants, >100 bpm in older children)
- characterized by: beat-to-beat heart rate variability with changes in activity, P waves present/normal, PR constant, QRS narrow
- **etiology:** HTN, fever, anxiety, sepsis, anemia/hypoxia, pain, PE, drugs, etc.
- differentiate from SVT by slowing the sinus rate (vagal massage, β-blockers) to identify sinus P waves

Premature Atrial Contractions
- may be normal variant or can be caused by electrolyte disturbances, hyperthyroidism, cardiac surgery, digitalis toxicity

Premature Ventricular Contractions
- common in adolescents
- benign if single, uniform, disappear with exercise, and no associated structural lesions
- if not benign, may degenerate into more severe dysrhythmias

Supraventricular Tachycardia
- abnormally rapid heart rhythm originating above the ventricles – most frequent sustained dysrhythmia in children
- no beat-to-beat HR variability, >220 bpm (infants) or >180 bpm (children), P waves absent/abnormal, PR indeterminable, QRS usually narrow
- pre-excitation syndromes (subset of SVT): WPW syndrome, congenital defect (see Cardiology and Cardiac Surgery, C25)

Complete Heart Block
- congenital heart block can be caused by maternal anti-Ro or anti-La (e.g. mother with SLE)
- often diagnosed in utero (may lead to development of fetal hydrops)
- clinical symptoms related to level of block (the lower the block, the slower the heart rate and greater the symptoms of inadequate cardiac output)
- symptomatic patients need a pacemaker

Paediatric vs. Adult ECG
Paediatric ECG findings that may be normal:
- HR >100 bpm
- Shorter PR and QT intervals and QRS duration
- Inferior and lateral small Q waves
- RV larger than LV in neonates, so normal to have:
  - RAD
  - Large precordial R waves
  - Upright T waves
  - Inverted T waves in the anterior precordial leads from early infancy to teen years

Heart Murmurs

- 50-80% of children have audible heart murmurs at some point in their childhood
- most childhood murmurs are functional (e.g. "innocent") without associated structural abnormalities and have normal ECG and radiologic findings
- in general, murmurs can become audible or accentuated in high output states (e.g. fever, anemia)

Table 15. Differentiating Heart Murmurs

	Innocent	Pathological
History and Physical	Asymptomatic	Symptoms and signs of cardiac disease (FTT, exercise intolerance)
Timing	SEM	All diastolic, pansystolic, or continuous (except venous hum)
Grade/Quality	<3/6; soft/blowing/vibratory	≥3/6 (palpable thrill); harsh
Splitting	Physiologic S2	May have fixed split or single S2
Extra Sounds/Clicks	None	May be present
Change of Position	Murmur varies	Unchanged

Table 16. Five Innocent Heart Murmurs

Type	Etiology	Location	Timing	Description	Age	Differential Diagnosis
Peripheral Pulmonic Stenosis	Flow into pulmonary branch arteries from main, larger, artery	Left upper sternal border	Systolic ejection	Neonates, low-pitched, radiates to axilla and back	Neonates, usually disappears by 3-6 mo	PDA Pulmonary stenosis
Still's Murmur	Flow across the pulmonic valve leaflets	Left lower sternal border	Systolic ejection	High-pitched, vibratory, LLSB or apex, SEM	3-6 yr	Subaortic stenosis Small VSD
Venous Hum	Altered flow in veins	Infraclavicular (R>L)	Continuous	Infraclavicular hum, continuous, R>L	3-6 yr	PDA
Pulmonary Flow	Flow through the pulmonic valve	Left upper sternal border	Systolic ejection	Soft, blowing, LUSB, SEM	8-14 yr	ASD Pulmonary stenosis
Supraclavicular Arterial Bruit	Turbulent flow in the carotid arteries	Supraclavicular	Systolic ejection	Low intensity, above clavicles	Any age	Aortic stenosis Bicuspid aortic valve

Infective Endocarditis

- see Infectious Diseases, ID15

Development

Approach to Global Developmental Delay

- also known as Early Developmental Impairment

Definition

- significant delay (at least 2 SDs below the mean with standardized tests) in at least two developmental domains (gross motor, fine motor, speech/language, cognitive, social/personal, activities of daily living) in a child <5 yr
- may predict a diagnosis of intellectual disability in the future
- after age 5, intellectual and physical disabilities are described (no longer a development 'delay' as catch up is not expected)

Epidemiology

- 5-10% of children have neurodevelopmental delay
- careful evaluation can reveal a cause in 50-70% of cases

Etiology

Broad category	Possible causes	Upper limit of diagnostic yield*
Prenatal Biological Factors	Genetic abnormalities Central nervous system deformities Metabolic issues	47%
Prenatal Environmental Factors	Teratogens/toxins (substances of abuse, medications, etc.) Infections	28%
Perinatal	Asphyxia and neonatal encephalopathy Premature birth Low birth weight Neonatal complications	21%
Postnatal	Neglect/unhealthy psychosocial environment Infections Trauma Severe jaundice (kernicterus) Toxins	55%

*Percentage of total cases of GDD or ID with an identified etiologic diagnosis who fall into this specific category

Clinical Features
- key questions in addition to standard paediatric history:
  - detailed developmental milestones: rate of acquisition, regression of skills
  - detailed prenatal, birth, postnatal history
  - detailed three-generation family history
  - detailed psychosocial history, including exposure to environmental toxins
  - associated problems: feeding, seizures, behaviour, sleep
- physical exam
  - micro/macrocephaly, dysmorphic features head-to-toe, hepatosplenomegaly, height and weight
  - **neurodevelopmental exam** (neurological exam, congenital abnormalities, cutaneous findings, dysmorphic features, current developmental level)
- investigations (guided by history and physical examination); see CPS step-wise algorithm
  - chromosomal microarray and Fragile X DNA testing are the first line tests
  - vision and hearing test, lead, CBC, blood gas, urea, creatinine, electrolytes with anion gap, ferritin, B_{12}, TSH, CK
  - EEG if suspected seizures
  - brain MRI if abnormal neuro exams, micro/macroecephalopathy
  - MECP2 in girls with clinical course suggestive of Rett's Syndrome
  - metabolic screening: glucose, electrolytes, lactate, ammonia, liver function, pyruvate, albumin, trigylcerides, uric acid, amino acids, urine organic acids, acylcarnitine profile, carnitine (free and total), creatine phosphokinase, homocysteine, iotinidase, copper, ceruloplasmin
  - OT, PT, and/or SLP assessments
  - Consider consultation with a genetic/metabolic specialist

Management
- dependent on specific area of delay
- therapy services (e.g. speech and language therapy for communication delay, OT and/or PT for motor delay), early intervention services (e.g. infant development services, Ontario Early Years Centres); access to daycare can support developmental units

Intellectual Disability

Definition
- state of functioning that begins in childhood and is characterized by limitations in both intelligence and adaptive skills
- historically defined as an IQ <70
- often preceded by diagnosis of global developmental delay
- must be diagnosed by a psychologist

Epidemiology
- 1-3% of general population; M:F=1.5:1

Clinical Features
- history
  - earlier age of onset correlates with greater severity of ID
  - well below average general intellectual functioning
  - significant deficits in adaptive functioning in at least 2 of: communication, self-care, home-living, social skills, self-direction, academic skills, work, leisure, health, safety
- physical exam
  - check growth, dysmorphic features, complete physical exam, detailed observation of behaviour/phenotype (i.e. social skills)
- investigations
  - standardized psychoeducational assessment (includes cognitive and adaptive functioning measures)
  - vision, hearing, and/or neurologic assessment
  - genetic and metabolic testing as indicated

Management
- main objective: enhance adaptive functioning level
- requires an interprofessional team with strong case coordination
- emphasize community-based treatment and early intervention
- behaviour management services, therapy services (e.g. OT, SLP), medications for associated conditions
- medications for associated conditions
- education: life skills, vocational training, communication skills, family education
- psychosocial support for individual and family; respite care, individual/family therapy

Prognosis
- higher rates of sensory deficits, motor impairment, behavioural/emotional disorders, seizures, psychiatric illness

Language Delay

Definition
- no universally accepted definition, but most often identified around 18 mo of age with enhanced well baby visit
- if formally tested, at least one standard deviation below mean of age on standardized testing
- can be expressive (ability to produce or use language), receptive (ability to understand language), or both

Epidemiology
- M>F
- ~10-15% of 2 y/o children have a language delay, but only 4-5% remain delayed after age 3
- ~6-8% of school-aged children have specific language impairment (many of whom were not identified before school entry)

Etiology
- intellectual disability
- selective mutism
- language specific learning disorder
- isolated language delay
- developmental disorders: cerebral palsy, autism spectrum disorder, constitutional language delay
- genetic/metabolic: DS, Fragile X syndrome, Williams syndrome, hypothyroidism, PKU, etc.
- mechanical problems: cleft palate, cranial nerve palsy, hearing impairment
- medical conditions: seizure disorder (includes acquired epileptic aphasia), degenerative neurologic disorders (i.e. Rett syndrome, Leigh encephalopathy), CP, TORCH infection, iron deficiency, lead poisoning, etc.
- psychosocial: neglect or abuse

Clinical Features
- history
  - concerns about hearing, delay in language development or regression in previously normal language development
  - delayed language milestones, presence of red flags, regression (see Table 9, *Developmental Milestones*, P8)
  - must determine if language delay is expressive, receptive, or mixed
  - assess social communication skills, including use of gestures
  - determine differences in behaviour at home, school, other social environments
  - risk factors: family history of speech and language delay, male, prematurity, low birth weight, hearing loss
- physical exam
  - guided by history: look for abnormal growth, dysmorphisms, unusual social interactions (lack of eye contact, not pointing)
  - include full exam of the external/internal ear (e.g. TM scarring), oral pharynx (e.g. cleft palate), and neurologic system (including tone)
- investigations
  - use of language specific screens in primary care setting: The Early Language Milestone, Communication and Symbolic Behavior Scales Developmental Profile Infant-Toddler Checklist
  - Clinical Adaptive Test/Clinical Linguistic and Auditory Milestone Scale (CAT/CLAMS), Modified Checklist for Autism in Toddlers (M-CHAT), etc.
  - developmental evaluation and observation during informal interaction
  - hearing, dental, and vision screening (audiology, dentistry and optometry referral)
  - CBC (to rule out anemia), venous blood lead levels, genetic/metabolic workup as indicated

Risk Factors for Sensorineural Hearing Loss
- Genetic syndromes/family history
- Congenital (TORCH) infections
- Craniofacial abnormalities
- <1500 g birth weight
- Hyperbilirubinemia/kernicterus
- Asphyxia/low APGAR scores
- Bacterial meningitis, viral encephalitis

Management
- specific to etiology
- referral to SLP most important, consider referral to Otolaryngology Head and Neck Surgery (OHNS), dental professionals, general support services
- consider other interventions specific to etiology
- prevention: parents can read aloud to their child, engage in dialogic reading, avoid baby talk, narrate daily activities, etc.

Primary care physicians should also suspect a receptive language delay in any young child with an expressive language delay

Prognosis
- depends on etiology – best prognosis for developmental speech delay
- if language delay persists beyond age 5, more likely to have difficulties in adulthood
- persistent language delay is associated with poor academic performance, behavioural problems, social isolation

Specific Learning Disorder

Definition
- specific and persistent failure to acquire academic skills despite conventional instruction, adequate intelligence, and sociocultural opportunity
- a significant discrepancy between a child's intellectual ability and their academic performance
- types: reading (dyslexia), writing, mathematics (dyscalculia)

Epidemiology
- prevalence: 10%
- high incidence of psychiatric comorbidity: anxiety, dysthymia, conduct disorder, major depressive disorder, oppositional defiant disorder, ADHD

Etiology
- pathogenesis is unknown, likely genetic factors involved
- learning disabilities may be associated with a number of conditions:
  - genetic/metabolic (e.g. Turner syndrome, Klinefelter syndrome)
  - perinatal: prematurity, low birth weight, birth trauma/hypoxia
  - postnatal: CNS damage, hypoxia, environmental toxins, FAS, psychosocial deprivation (understimulation), malnutrition
- poor visual acuity is NOT a cause

Risk Factors
- positive family history, prematurity, developmental and mental health conditions, neurologic disorders (e.g. seizure disorders, neurofibromatosis), history of CNS infection/irradiation/traumatic injury, prenatal alcohol exposure, chromosomal disorders

Clinical Features
- history and physical exam
  - school difficulties (academic achievement, behaviour, attention, social interaction, over-reliance on teacher)
  - development of negative self-concept ➔ reluctance to participate even in areas of strength
  - social issues: overt hostility towards parents/teachers; difficulties making friends, bullying, and anxiety
  - look for dysmorphisms, complete physical exam; signs and symptoms of OSA
- investigations
  - psychoeducational assessment, educational history from school staff
  - individual scores on achievement tests in reading, mathematics, or written expression (WISC III, WRAT) >2 SD below that expected for age, education, and IQ
  - evaluate attention, memory, expressive language, coordination skills

Management
- provide quality instruction for specific learning disability
- advocate for school supports: modifying the curriculum and/or providing accommodations (e.g. scribe for writing, extra time for tests, photocopied notes, etc.)
- individualized Education Plan (IEP): a written plan that describes the strength and needs of the student, services established to meet these needs, and how these services should be delivered
- specialized education placements that can provide educational remediation

Prognosis
- limited information available about persistence of learning disabilities over time
- low self-esteem, poor social skills, 40% school drop-out rate

Fetal Alcohol Spectrum Disorder

Definition
- term describing the range of effects of prenatal exposure to alcohol, including physical, mental, behavioural, and learning disabilities
- abstinence from alcohol during pregnancy is recommended
- spectrum includes: FAS, partial FAS, ARBD (alcohol related birth defects) and ARND (alcohol related neurodevelopmental disorder)

Epidemiology
- prevalence of FAS and FASD is 0.1% and 1.0%, respectively
- most common preventable cause of intellectual disability

Pathogenesis
- specific mechanism of FASD is unknown, but hypotheses include nutritional deficits, toxic effects of acetaldehyde, alteration of placental transport, abnormal protein synthesis, and altered cerebral neurotransmission

Diagnosis
- often misdiagnosed or missed entirely
- multidisciplinary team needed to make diagnosis and involves a complex physical exam and neurodevelopmental assessment
- diagnosis of ARBD and ARND require evidence of maternal alcohol consumption during pregnancy
- criteria for diagnosis of FAS
  - FASD with sentinel facial features: 1. presence of facial features, 2. maternal alcohol consumption confirmed or unknown, 3. evidence of neurodevelopmental impairment OR microcephaly in infants and young children
  - FASD without sentinel facial features: evidence of neurodevelopmental impairment, maternal alcohol consumption confirmed
  - **sentinel facial features**: short palpebral fissures (<2 SD below mean), flattened philtrum, thin upper lip (having all 3 features is highly specific for alcohol exposure
  - **neurodevelopmental dysfunction (need ≥3):** motor skills; neuroanatomy/neurophysiology; cognition; language; academic achievement; memory; attention; executive function (impulse control and hyperactivity); affect regulation; adaptive behaviour, social skills or social communication, or microcephaly in infant and young children
- criteria for diagnosis of ARBD
  - congenital anomalies; malformations and dysplasias of the cardiac, skeletal, renal, ocular, and auditory systems
- criteria for diagnosis of ARND
  - cannot be definitively diagnosed in children <3 yr
  - CNS dysfunction (similar to FAS)
  - complex pattern of behavioural or cognitive abnormalities inconsistent with developmental level that cannot be explained by familial background or environment alone

Management
- early diagnosis is essential to prevent secondary disabilities by early connection to therapies and supports
- no cure, but individuals with FASD and their families should be linked to community resources and services to improve outcomes

Prognosis
- secondary disabilities include unemployment, mental health problems, difficulties with the law, inappropriate sexual behaviour, disrupted school experience, peer problems
- prognosis may be improved if diagnosed before age 6, social and educational supports available, and nurturing living environment

Attention Deficit Hyperactivity Disorder

- see Psychiatry, *Neurodevelopmental Disorders*, PS47

Autism Spectrum Disorder

- see Psychiatry, *Neurodevelopmental Disorders*, PS47

Motor Delay

- see *Cerebral Palsy*, P87 and Medical Genetics, *Duchenne Muscular Dystrophy*, MG9

Endocrinology

Antidiuretic Hormone

Diabetes Insipidus
- see Endocrinology, E23 and Nephrology, NP12

Syndrome of Inappropriate Antidiuretic Hormone
- see Endocrinology, E23 and Nephrology, NP11

Diabetes Mellitus

DIABETES MELLITUS TYPE 1
- see Endocrinology, E8

Epidemiology
- most common form of DM in children, M=F
- variable prevalence internationally, affects 32 in 100000 children in Canada
- can present at any age, but bimodal peaks at 5-9 y/o and at 10-14 y/o

Clinical Features
- can present with polyuria (may manifest as nocturia or secondary enuresis), polydipsia, weight loss (lack of insulin leading to a catabolic state), polyphagia, perineal candidiasis (younger children), visual disturbances, and DKA (30%, with greater incidence in younger children)
- DKA clinical features – anorexia, nausea/vomiting, abdominal pain, Kussmaul breathing, tachycardia, reduced skin turgor, drowsiness, lethargy, coma

Management
- patients and families are best managed with a family-centred paediatric multidisciplinary team able to provide education, ongoing care, and psychosocial support surrounding survival skills, meal plans, and insulin injections as a cornerstone of treatment
  - diet with consistent levels of carbohydrates, avoiding foods with high glycemic index is advised
  - ~60 min aerobic exercise recommended daily, extensive activity may cause prolonged hypoglycemia or hyperglycemia
  - administer influenza immunization yearly to avoid complications to management
- blood glucose monitoring is especially important in children as they are more susceptible to hypoglycemia (lethargy, unusual behaviour, tremor, pallor, tachycardia, diaphoresis, seizure, coma)
  - administer simple PO carbohydrate (i.e. sweetened fruit juice) for mild hypoglycemia and IM glucagon or IV dextrose for severe hypoglycemia
- if DKA present: ABCs, 100% O_2, admit, monitor, correct fluid losses (only isotonic fluids, with deficits replaced over 48 h), conduct ECG (assess for abnormal T waves), administer insulin (avoid bolus, and delay infusion until 1-2 h after fluid resuscitation) and restore glucose gradually (SC if mild; IV infusion if moderate or severe), correct electrolyte disturbances, identify/treat precipitating event, avoid complications (i.e. cerebral edema)
  - low threshold to investigate (CT/MRI) and treat DKA, as cerebral edema is a major concern in the paediatric population
    - signs of neurological deterioration: headache, bradycardia, irritability, decreased LOC, incontinence, specific neurological signs
    - administer mannitol for cerebral edema
  - frequent BG, fluid and electrolyte monitoring
  - see Endocrinology, E10
- screen for micro- and macrovascular complications (regular ophthalmology assessments, microalbuminuria, diabetic foot exam), concurrent autoimmune diseases (thyroiditis, celiac disease, etc.), mental health issues (depression, eating disorders, etc.), HTN, dyslipidemia

Prognosis
- no cure currently
- short-term complications
  - hypoglycemia
    - due to missed/delayed meals, excess insulin or exercise, illness, alcohol ingestion, psychosocial factors
    - can lead to seizures and/or coma as well as permanent neurologic complications
  - hyperglycemia
    - due to intercurrent illness, diet-to-insulin mismatch
    - risk of end-organ damage
  - DKA: due to missed insulin doses, infection; most common cause of death

Diagnostic Criteria for DM (Types 1 and 2) in Children
1. Symptoms (polyuria, polydipsia, weight loss, etc.) and hyperglycemia (Random glucose ≥11.1 mmol/L)
OR
2. Two of the following on one occasion:
- Fasting glucose ≥7.0 mmol/L
- 2 h plasma glucose during OGTT ≥11.1 mmol/L
- HbA1c ≥6.5%
OR
3. One of the following on two separate occasions*
- Fasting glucose ≥7.0 mmol/L
- 2 h plasma glucose during OGTT ≥11.1 mmol/L
- HbA1c ≥6.5%

*HbA1c is not recommended as the sole diagnostic test in children and adolescents
* HbA1c has reduced reliability when hemoglobinopathies or increased RBC turnover (i.e. G6PD) present

Blood Glucose Targets
Current guidelines recommend an HbA1c target of 7% for all age groups, with a less stringent target of <7.5% or <8% if unable to articulate symptoms of hypoglycemia/unawareness or history of severe hypoglycemia; a less stringent target of 6.5% may be recommended if low hypoglycemia risk

- long-term complications
  - microvascular: retinopathy, nephropathy, neuropathy
  - macrovascular: metabolic syndrome, CVD, CAD, PVD
  - increased risk of other autoimmune diseases
  - hypertension, dyslipidemia

DIABETES MELLITUS TYPE 2

- see Family Medicine, FM25 and Endocrinology, E8
- impaired glucose metabolism due to increased peripheral insulin resistance and relative impairment in insulin secretion
- rare before age 10, but more common in older children/adolescents (mean age of ~14 y/o)
- prevalence is rising mainly due to the increased incidence of childhood obesity
- risk factors: obesity, positive family history, female sex, conditions associated with insulin resistance (e.g. PCOS), hyperglycemia exposure *in utero*, certain ethnic groups (see Endocrinology, E8)
  - risk reduced with breastfeeding
- clinical feature may be similar to that of T1DM, though most children are asymptomatic (~40%)
  - may present in DKA or hyperglycemic hyperosmotic nonketotic state
  - screening recommended in overweight or obese asymptomatic children after puberty or >10 yr old if ≥1 risk factors (T2DM in first or second degree relative, high-risk ethnic group, signs of insulin resistance, gestational diabetes) at least every 3 yr
  - screening and diagnostic investigations – fasting plasma glucose recommended, 2 h oral glucose tolerance test (higher detection in severe obesity, BMI >99th percentile, and with multiple risk factors), HbA1c
  - pancreatic autoantibodies (anti-glutamate decarboxylase, anti-islet and anti-insulin antibodies) to exclude T1DM if unclear
- management
  - initial therapy with insulin used for severe metabolic decompensation at diagnosis (DKA, A1C >9%), can wean off
  - initiate lifestyle modification program, including diet, weight loss, physical activity (moderate to vigorous activity for at least 60 min/d; screen time less than 2 h/d)
    - glycemic target: HbA1c ≤7%
  - if glycemic targets not achieved within 3-6 mo from diagnosis with lifestyle intervention alone, either metformin (first line), glimepiride, or insulin should be initiated
    - metformin can be initiated at diagnosis if HbA1c >7%
  - if glycemic target not met with metformin, add liraglutide with/without basal insulin (especially if severe hyperglycemia – HbA1c >8.5%)
  - monitor HbA1c every 3 mo
  - advise patient to monitor finger-stick blood glucose levels if on medication with risk of hypoglycemia, are changing medication regimen, have not met treatment goals, or have intercurrent illness
  - screening – same as T1DM plus annual screening for PCOS and nonalcoholic fatty liver disease (NAFLD)
- prognosis: includes microvascular and macrovascular complications similar to T1DM

See Landmark Paediatric Trials table for more information on TODAY, which details the efficacy of three treatments aimed at achieving durable glycemic control in children and adolescents with recent-onset type 2 diabetes.

See Landmark Paediatric Trials table for more information on ELLIPSE, which details the safety and effectiveness of liraglutide and metformin combined therapy for youth with type 2 diabetes.

Growth

- see *Failure to Thrive*, P13

APPROACH TO SHORT STATURE

Definition

- short stature: height <3rd percentile
- poor growth evidenced by growth deceleration (height crosses major percentile lines, decreased growth velocity

Epidemiology

- ~2.5% of the population by definition

Etiology

- ABCDEFG (see *Short Stature DDx* Memory Aid)
  - Pathologic short stature (if reduced growth velocity)
  - Non-pathologic short stature (if normal growth velocity)

Clinical Features

- history and physical exam
  - family history of growth and pubertal onset
  - plot on growth curve (special growth charts available for Turner syndrome, achondroplasia, DS, and other genetic syndromes)
    - decreased growth velocity often more worrisome than actual height
  - assess for dysmorphic features, disproportionate short stature
  - assess for headaches, vision changes, stigmata of endocrine abnormalities

Short Stature DDx

ABCDEFG
Alone (neglected infant)
Bone dysplasias (rickets, scoliosis, mucopolysaccharidoses, achondroplasia)
Chromosomal (Turner, Down)
Delayed growth (CDGP)
Endocrine (hypopituitary, low GH, Cushing, hypothyroid)
Familial (familial short stature)
GI malabsorption (celiac, Crohn's)

  - risk factors for GH deficiency: previous head trauma, history of intracranial bleed or infection, head surgery or irradiation, positive family history, breech delivery
- investigations
  - calculate mid-parental height: children are usually in a percentile between their parents' height
    - mid-parental height male = (mother + father's height in cm + 12.5 cm)/2
    - mid-parental height female = (mother + father's height in cm – 12.5 cm)/2
    - likely low mid-parental height in familial short stature (FSS)
  - AP x-ray of left hand and wrist for bone age
    - Constitutional delay of growth and puberty (CDGP) may be distinguished from FSS based upon delayed bone age
  - further investigations recommended with severe short stature or decreased growth velocity, guided by history/physical (e.g. endocrine (TSH/T4, GH testing etc.), chronic illness (e.g. CBC, creatinine, electrolytes, celiac screen, sweat chloride etc.), genetic (e.g. microarray, karyotype if aneuploidy suspected), etc.

Management

- depends on etiology and severity of problem as perceived by parents/child
- no treatment for non-pathological short stature, except for idiopathic short stature (height <3rd percentile without any endocrine, metabolic or other disease etiology)
- GH therapy for GH deficiency: if administered at an early age, can help patients achieve adult height requirements
    - GH shown to be deficient by 2 different stimulation tests (with arginine, glucagon, insulin)
    - growth velocity <3rd percentile or height <3rd percentile
    - bone age x-rays show unfused epiphyses/delayed bone age
- support and management of resultant self-image issues, social anxiety, etc.

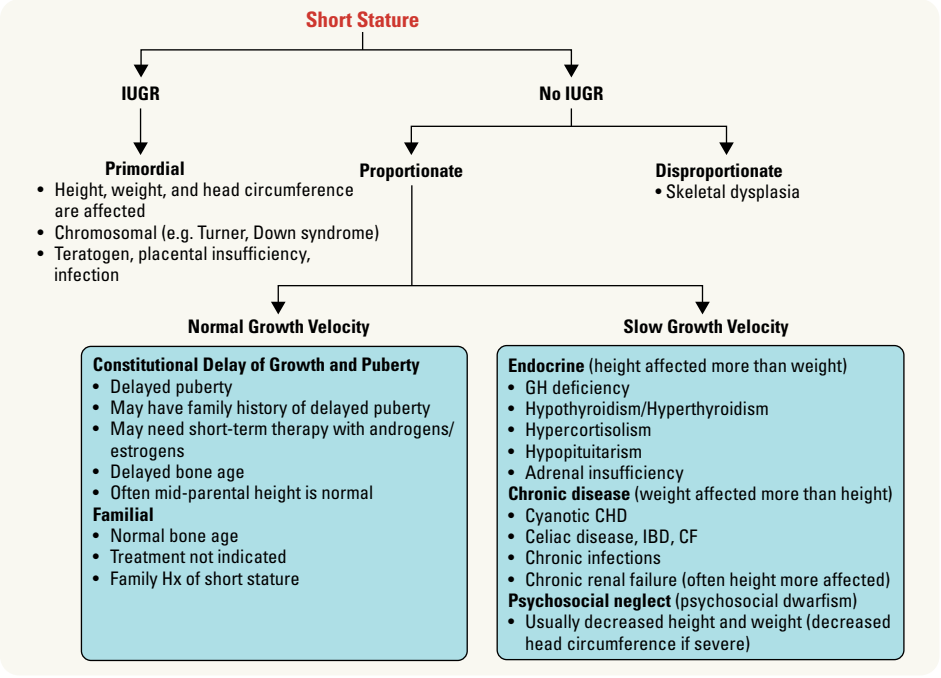

Figure 7. Approach to the child with short stature

TALL STATURE

- height greater than two SD above the mean for a given age, sex, and race

Etiology

- constitutional/familial
- endocrine: Beckwith-Wiedemann syndrome, hyperthyroidism, hypophyseal gigantism, precocious puberty
- genetic: homocystinuria, Klinefelter syndrome, Marfan syndrome, Sotos syndrome

Hypercalcemia/Hypocalcemia/Rickets

- see Endocrinology, E44, E45, E49

Hyperthyroidism and Hypothyroidism

- may be congenital or acquired (for acquired causes, see Endocrinology, E27)

CONGENITAL HYPERTHYROIDISM

- also known as neonatal Graves' disease

Epidemiology

- ~1 in 25000 neonates, M=F

Etiology

- typically caused by transplacental transfer of TSH receptor antibody (TRAb)
- rare causes include mutations in the TSH receptor pathway

Clinical Features

- history and physical exam
  - maternal history of thyroid pathology and management
  - low birthweight, IUGR, microcephaly, premature birth, tachycardia, irritability, frontal bossing, triangular facies, hepatosplenomegaly, goitre, flushing, sweating

Investigations

- TSH receptor antibody levels during the 3rd trimester or in the cord blood
- neonatal TSH, T3, free T4

Management

- methimazole and β-adrenergic blocker (e.g. propranolol)

Prognosis

- with prompt treatment, hyperthyroidism improves
  - however, long-term cognitive and CNS problems can still occur
- risk for development of central hypothyroidism later in life

CONGENITAL HYPOTHYROIDISM

Epidemiology

- incidence: 1 in 2000-4000 newborn births; F:M=2:1
- one of the most common preventable causes of intellectual disability

Etiology

- may be classified as permanent or transient congenital hypothyroidism (CH)
  - subcategorize into primary (85% dysgenesis, 15% thyroid gland disorder), secondary/central (pituitary/hypothalamic issue), or peripheral CH (deficits in thyroid hormone transport, metabolism, or action)
- causes of transient hypothyroidism: maternal antibody-mediated, iodine deficiency (rare in developed countries), prenatal exposure to antithyroid medications; neonatal iodine deficiency/excess, congenital liver hemangiomas, certain gene mutations

Clinical Features

- history and physical exam
  - usually asymptomatic in neonatal period because maternal T4 crosses the placenta
  - prolonged jaundice, feeding difficulty, lethargy, constipation, umbilical hernia, macroglossia, large fontanelles, puffy face, swollen eyes, hypotonia (signs/symptoms develop over first few mo)
  - examine for congenital malformations (especially cardiac) and dysmorphic features
  - central hypothyroidism associated with hypoglycemia, micropenis, undescended testes, features of diabetes insipidus
  - most commonly presents as a positive newborn screen result
- investigations
  - all infants should be screened for primary CH
  - repeat screening at 2 wk for infants at high-risk: preterm, SGA, infants in NICU, specimen collection <24 h of life, multiple births
  - diagnosis through newborn screening of TSH (most sensitive for primary CH) or free T4; abnormal results should be confirmed with serum levels from venipuncture
    - ↑TSH, ↓free T4 in primary CH
    - ↓TSH, ↓free T4 in secondary CH
  - primary CH (optional): radioisotope scanning/ultrasound of thyroid for severity, serum thyroglobulin, maternal antithyroid antibodies, urinary iodine
  - secondary CH: MRI, gene analysis, eye exam for optic nerve hypoplasia (assess pituitary)

Management
- thyroxine replacement, hormone normalization should be done within 2 wk to avoid cognitive impairment
- counsel against using soy based formulas

Prognosis
- excellent outcome if treatment started within 1-2 mo of birth
- if treatment started after 3-6 mo of age, may result in permanent developmental delay and/or disability (mild to profound), intellectual impairment, poor growth, hearing loss

Disorders of Sexual Development

AMBIGUOUS GENITALIA

Definition
- newborn or child whose sex is difficult to assign based on the appearance of genitalia
- subtype of DSD: a condition in which development of chromosomal, gonadal, or anatomic sex is atypical
- subtypes: 46,XX DSD, 46,XY DSD, ovotesticular DSD (true hermaphrodite)

Epidemiology
- incidence of genital abnormalities at birth is as high as 1 in 300
- prevalence of complex anomalies with true sexual ambiguity much lower at ~1 in 5000

Etiology
- 46,XY DSD
  - inborn error of testosterone biosynthesis or Leydig cell hypoplasia
  - 5-α-reductase deficiency, androgen receptor deficiency or insensitivity
  - LH/hCG unresponsiveness
- 46,XX DSD
  - virilizing CAH (most common)
  - maternal source: virilizing ovarian or adrenal tumours, untreated maternal CAH, placental aromatase deficiency
- ovotesticular DSD
  - both ovarian follicles and seminiferous tubules in the same patient with a 46,XX karyotype
  - mixed gonadal dysgenesis

Risk Factors
- parental consanguinity, positive family history of ambiguous genitalia, early childhood illness/death, or primary amenorrhea, maternal medications during pregnancy (e.g. androgens, progesterones, danazol, phenytoin, aminoglutethimide, endocrine disruptors)

Clinical Features
- history
  - thorough obstetrical history, including prenatal screens, maternal medications, and maternal virilization in pregnancy
  - family history: autosomal recessive pattern may suggest CAH, X-linked recessive pattern may suggest androgen insensitivity syndrome
- physical exam
  - XY: small phallus, hypospadias, bilateral cryptorchidism (undescended testicles)
  - XX: clitoromegaly, labioscrotal fusion
  - look for concurrent midline defects, dysmorphic features, and congenital abnormalities
- investigations
  - karyotype and genetic workup, including FISH for SRY gene, as indicated
  - blood work: electrolytes and renin (evidence of salt-wasting in CAH); 17-OH-progesterone, androgens, FSH and LH, glucose
  - imaging: abdominal and pelvic U/S to look for gonads, uterus, and vagina

Management
- avoid announcement of probable sex or use of personal pronouns until all tests are complete
- continuous psychosocial support for parents and child during development
- promote individualized management with respect to sex of rearing, surgical intervention, hormonal therapy, and preservation of fertility

CONGENITAL ADRENAL HYPERPLASIA

Definition
- autosomal recessive disorder characterized by the partial or total defect of various synthetic enzymes required for cortisol and aldosterone production in the adrenal cortex
  - adrenal cortex normally produces balanced levels of aldosterone, cortisol, and androgens

Epidemiology
- occurs in ~1 in 15000 live births
- most common cause of ambiguous genitalia in genotypically normal females (46,XX)

Etiology
- 21-OH responsible for ~95% of CAH cases
- results in ↓ cortisol and aldosterone production with shunting toward ↑↑ androgens
- cortisol deficiency leads to elevated ACTH, which causes adrenal hyperplasia
- rarer causes include deficiencies in 11-OH, cholesterol desmolase, 17-OH, and 3-HSD

Clinical Features
- depends on which enzyme in cortisol synthesis pathway is defective
- presentation of 21-OH deficiency can be divided into:
  - classic deficiency with salt wasting: inadequate aldosterone resulting in FTT, hyperkalemia, hyponatremia, hypoglycemia, acidosis (majority of classic CAH types)
  - classic deficiency without salt wasting: simple virilization with adequate aldosterone levels
    - females typically present with genital ambiguity, amenorrhea, precocious puberty, polycystic ovaries, hirsutism
    - males typically asymptomatic at birth, may show hyperpigmentation (from overproduction of melanocyte stimulating hormone), penile enlargement, rapid growth and accelerated skeletal maturation; present with signs of virilization later in life
  - non-classic CAH – mild androgen excess, sometimes asymptomatic, precocious puberty and/or virilization present later in life, rarely associated with Addisonian crises (may be indistinguishable from PCOS)
- 21-OH deficiency screening is part of many newborn screening programs across North America (non-classical variant rarely detected)
- high serum levels of 17-OH progesterone in random blood sample diagnostic for 21-OH deficiency
  - assess plasma ACTH, serum electrolytes, plasma glucose, plasma aldosterone, plasma renin activity, blood gas
  - ultrasound – look for enlarged adrenal gland and presence of uterus

Management
- correct any abnormalities in fluids, electrolytes, or serum glucose
- provide glucocorticoids (e.g. hydrocortisone)/mineralocorticoids (fludrocortisone) to reduce ACTH levels, extra glucocorticoids in times of stress
- psychosocial support

Prognosis
- complications if untreated include virilization, acne, salt wasting, hypotension

NORMAL PUBERTAL DEVELOPMENT

Physiology
- puberty occurs with the maturation of the HPG axis
- ↑ pulsatile release of GnRH → ↑ release of LH and FSH → maturation of gonads, release of sex steroids → secondary sexual characteristics
- adrenal production of androgens also required

Females
- onset: age 8-13 (may start as early as 7 in girls of African descent)
- usual sequence
  1. thelarche: breast budding
  2. pubarche: axillary hair, body odour, mild acne
  3. growth spurt
  4. menarche: mean age 12.5 yr; indicates that growth spurt is almost complete; menses may be irregular in duration and length of cycle
- early puberty is common and often constitutional, late puberty is rare (rule out organic causes)

Males
- onset: age 9-14
- usual sequence
  1. testicular enlargement
  2. penile enlargement
  3. pubarche: axillary and facial hair, body odour, mild acne
  4. growth spurt: occurs later in boys
- early puberty is uncommon (rule out organic causes), late puberty is common and often constitutional
- gynecomastia (transient development of breast tissue) is a common self-limited condition seen in 50% of males during puberty (but any discharge from nipple or fixed mass should be investigated)

Maturity Rating (formerly Tanner Staging)
- scale used in paediatrics that defines physical measurements of development based on external primary and secondary sex characteristics

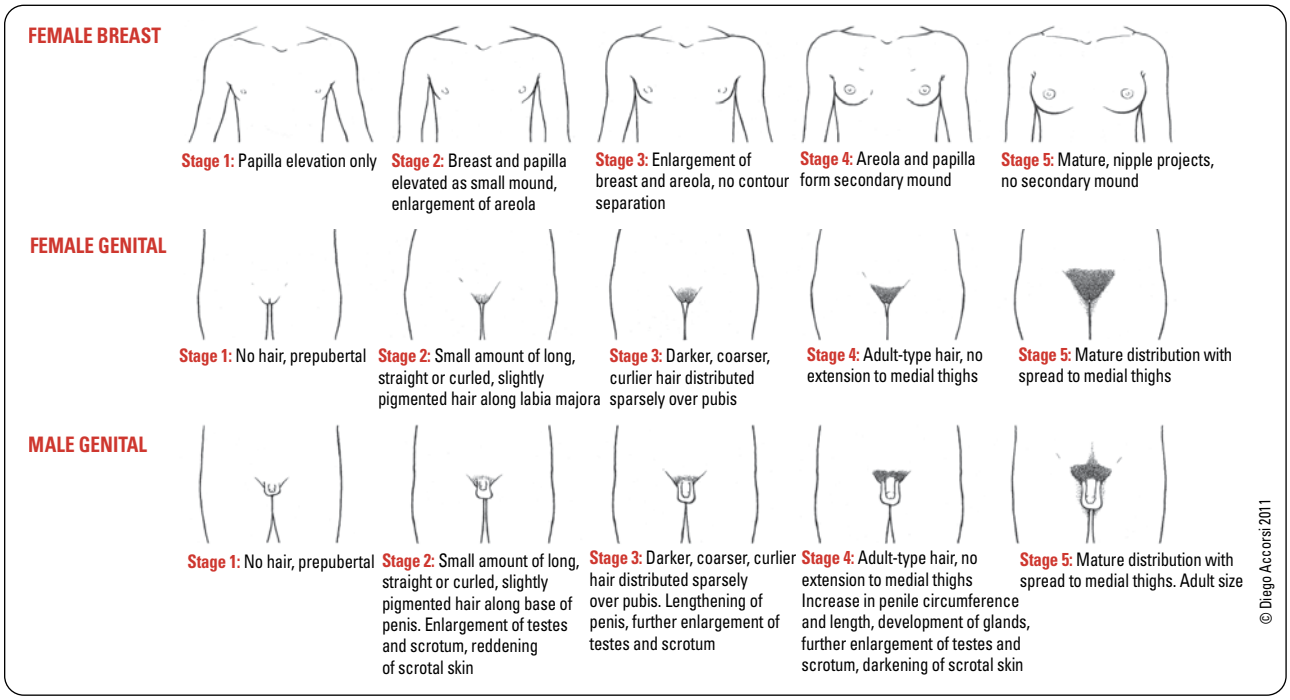

Figure 8. Tanner staging

PRECOCIOUS PUBERTY

Definition
- development of secondary sexual characteristics 2-2.5 SD before population mean
- <8 yr for females, <9 yr for males

Epidemiology
- 1 in 10000; F>M

Etiology
- usually idiopathic in females (90%), more suggestive of pathology in males (50%)
- central (GnRH dependent)
  - hypergonadotropic hypergonadism; hormone levels as in normal puberty
  - premature activation of the HPG axis
  - differential diagnosis: idiopathic or constitutional (most common in females), obesity, CNS disturbances (tumours, hamartomas, post-meningitis, increased ICP, radiotherapy), NF, primary severe hypothyroidism
- peripheral (GnRH independent)
  - hypogonadotropic hypergonadism
- differential diagnosis
    - males: testicular tumour, gonadotropin/hCG secreting tumour (hepatoblastoma, intracranial teratoma, germinoma)
    - females: ovarian cysts/tumours
    - both: adrenal disorders (CAH, adrenal neoplasm), exogenous steroid administration, McCune-Albright syndrome, aromatase excess syndrome, rarely primary hypothyroidism (Van Wyk-Grumbach syndrome)

Clinical Features
- history
  - symptoms of puberty, family history of precocious puberty, medical illness
- physical exam
  - growth velocity
    - prepubertal: minimum 4 cm/yr
    - growth spurt: males 10-14 cm/yr, females 8-12 cm/yr
    - complete physical exam, including Tanner staging and neurological assessment
- investigations
  - initial screening tests: bone age, serum hormone levels (estradiol, testosterone, LH, FSH, TSH, free T4, DHEA-S, 17-OH-progesterone, prolactin)
  - secondary tests: MRI head, pelvic U/S, β-hCG, GnRH, and/or ACTH stimulation test

A child (generally boys and girls <6/7 y/o) with proven central precocious puberty should receive an MRI of the brain

Management
- indications for medical intervention to delay progression of puberty: rapid advancement of puberty, early age, risk of compromise of final adult height, psychological
- central causes: goals are to preserve height and alleviate psychosocial stress; GnRH agonists (e.g. leuprolide) most effective
- peripheral causes: goal is to limit effects of elevated sex steroids; medications that decrease the production of a specific sex steroid or block its effects (e.g. ketoconazole, spironolactone, tamoxifen, anastrozole); surgical intervention

DELAYED PUBERTY

Definition
- failure to develop secondary sex characteristics by 2-2.5 SD beyond the population mean
  - for males: lack of testicular enlargement by age 14
  - for females: lack of breast development by age 13 OR absence of menarche by age 16 or within 5 yr of pubertal onset

Epidemiology
- M>F

Etiology
- usually constitutional delay in males, more suggestive of pathology in females
- central causes
  - constitutional delay in activation of HPG axis (most common)
  - hypogonadotropic hypogonadism (e.g. various genetic syndromes (e.g. Kallmann syndrome), hypothalamic/pituitary disorders, chronic illness, hypothyroidism, hyperprolactinemia, poor nutrition, excessive exercise, etc.)
- peripheral causes
  - hypergonadotropic hypogonadism (e.g. primary gonadal failure, gonadal damage, Turner syndrome, Klinefelter syndrome, hormone deficiency, androgen insensitivity syndrome, etc.)

Clinical Features
- history: weight loss, short stature, family history of puberty onset, medical illness, high performance athletes (females), congenital anomalies or neurologic symptoms
- physical exam
  - growth velocity
    - prepubertal: minimum 4cm/yr
    - growth spurt: males 10-14 cm/yr, females 8-12 cm/yr
    - complete physical exam, including Tanner staging and neurological assessment
- investigations
  - initial screening tests: bone age, serum hormone levels (estradiol, testosterone, LH, FSH, TSH, free T4, IGF-1), CBC, electrolytes, BUN, Cr, LFTs, liver enzymes, ESR, CRP, IGF-1, urinalysis
  - secondary tests: MRI head, pelvic U/S, karyotype, IBD panel, celiac disease panel, LH levels following GnRH agonist, prolactin

Management
- identify and treat underlying cause
- hormonal replacement: cyclic estradiol and progesterone for females, testosterone for males

Fluids and Electrolytes

Approach to Infant/Child with Dehydration

Etiology
- decreased intake: poor oral intake during acute illness, breastfeeding difficulties, eating disorders
- increased losses: common sites include GI tract (diarrhea, vomiting, bleeding), skin/mucous membranes (fever, burns, hemorrhage, stomatitis), urine (osmotic diuresis (e.g. hyperglycemia, DKA)), diuretic therapy, DI, post-obstructive/post ATN recovery diuresis), and respiratory tract (tachypnea, bronchiolitis, pneumonia)

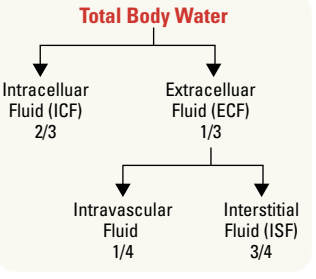

Figure 9. Body fluid compartments

Management

- if suspect dehydration based on history (acute illness, decreased number of wet diapers, lethargy, changes in mental status, increased thirst, etc.), you must:

1) Determine degree of extracellular volume contraction

Table 17. Assessment of Degree of Extracellular Volume Contraction Based on Physical Exam

	Mild	Moderate	Severe
<2 yr	5%*	10%*	15%*
>2 yr	3%*	6%*	9%*
Pulse	Normal, full	Rapid	Rapid, weak
Blood Pressure	Normal	Low to normal	Decreased in shock (very late finding in paediatrics and very dangerous)
Urine Output	Decreased	Markedly decreased	Anuria
Oral Mucosa	Slightly dry	Dry	Parched
Anterior Fontanelle	Normal	Sunken	Markedly sunken
Eyes	Normal	Sunken	Markedly sunken
Skin Turgor	Normal	Decreased	Tenting
Capillary Refill	Normal (<3 s)	Normal to increased	Increased (>3 s)

* Note that percentages refer to percent loss of pre-illness body weight

Assessment of Severity of Dehydration

C BASE H_2O
Capillary refill
BP
Anterior fontanelle
Skin turgor
Eyes sunken
HR
Oral mucosa
Output of urine

2) Determine the likely electrolyte disturbance

- dependent on etiology of dehydration and type of fluid loss (isotonic vs. hypertonic vs. hypotonic)

Table 18. Electrolyte Content of Various Bodily Fluids

Bodily Fluid	Na^+ (mmol/L)	K^+ (mmol/L)	Cl^- (mmol/L)	HCO_3^- (mmol/L)
Saliva	30-80	20	70	30
Gastric Juice	60-80	15	100	0
Pancreatic Juice	140	5-10	60-90	40-100
Bile	140	5-10	100	40
Small Bowel	140	20	100	25-50
Large Bowel	75	30	30	0
Sweat	20-70	5-10	40-60	0

- for moderate and severe dehydration, initial investigations should include urinalysis and blood work examining electrolytes (Na^+, K^+, Cl^-), glucose, acid-base disturbances (blood pH, pCO_2, HCO_3^-), and impaired renal function (creatinine, BUN)

3) Determine if the child requires PO or IV rehydration

- dehydrated child must receive adequate fluid management, including replacing deficits ongoing losses and maintenance fluids
- oral rehydration therapy (ORT) indication: mild to moderate dehydration
  - advantages: ↓ cost, no IV needed, no increase in incidence of iatrogenic hyper/hyponatremia, parental involvement in therapy
- indications for IV rehydration therapy: severe dehydration requiring close monitoring and frequent assessment of electrolytes, inability to tolerate ORT (e.g. vomiting, alteration in mental status, ileus, monosaccharide malabsorption, etc.), inability to provide ORT, failure of ORT in providing adequate rehydration (e.g. persistent diarrhea or vomiting)

4) Return the child to a normal volume and electrolyte status by replacing current deficits and ongoing losses

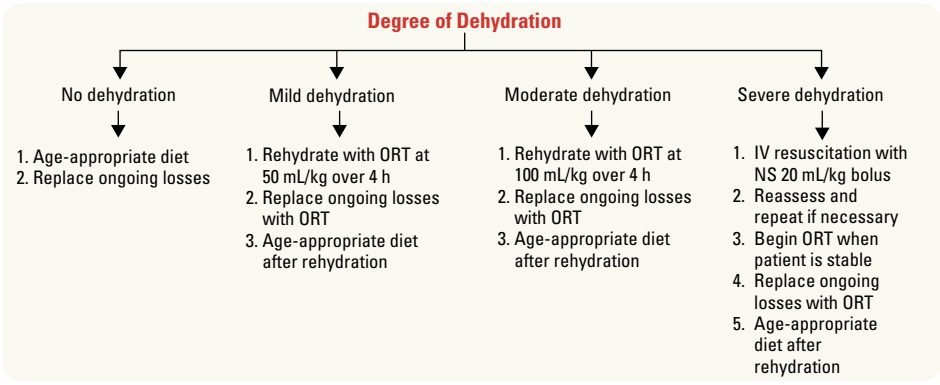

Figure 10. Algorithm for deficit replacement and replacement of ongoing losses in the dehydrated child

Special Consideration – SIADH
- **Clinical Signs**: hyponatremia and excretion of concentrated urine
- **Risk Factors**: certain medications (e.g. morphine), postoperative, pain, N/V, pulmonary disease (e.g. pneumonia), CNS disease (e.g. meningitis)
- **Caution**: acute hyponatremia is associated with rapid administration of hypotonic IV fluids, this can lead to cerebral edema and brain herniation or central pontine myelinolysis

5) Provide the appropriate fluid and electrolyte maintenance daily requirements

Table 19. Maintenance Fluid Requirements

Body Weight	100:50:20 Rule (24 h maintenance fluids)	4:2:1 Rule (hourly rate of maintenance fluids)
1-10 kg	100 cc/kg/d	4 cc/kg/h
11-20 kg	1000 cc + 50 cc/kg/d for every kg >10 kg	40 cc + 2 cc/kg/h for every kg >10 kg
>20 kg	1500 cc + 20 cc/kg/d for every kg >20 kg	60 cc + 1 cc/kg/h for every kg >20 kg

- prior to starting IV fluids, serum electrolyte values should be measured
- in children, all maintenance fluids should have a dextrose component due to their higher risk of hypoglycemia, especially if they are NPO
- common IV fluid combinations used in paediatrics
  - NS bolus for dehydration
  - for maintenance:
    - newborn: D10W
    - 1st mo of life: D5W/0.45 NS + KCl 20 mEq/L (only add KCl if voiding well)
    - children without special considerations: D5W/NS + KCl 20 mEq/L – decreased risk of hyponatremia
  - other options: D5W0.45%NS + KCl 20 mEq/L
- most important thing to remember when correcting Na+ aberrations due to fluid deficits
  - risk of cerebral edema with rapid rehydration with hypotonic or isotonic solutions (i.e. NS)
    - therefore replace fluid slowly with close monitoring
    - aim to adjust (increase or decrease) plasma [Na^+] by no more than 12 mmol/L/d
- management depends on etiology, severity of symptoms, and timing (acute vs. chronic)

6) Continue to monitor fluid and electrolyte status

- accurate monitoring of daily fluid intake (PO and IV) and ongoing losses (urine output, diarrhea, emesis, drains)
- if child receiving >50% of maintenance fluids through IV, serum electrolyte values should be monitored daily and therapy adjusted accordingly
- avoid iatrogenic hyper/hyponatremia, keep the possibility of SIADH in mind (indicated by hyponatremia and concentrated urine)

Gastroenterology

Vomiting

History

- characteristic of emesis (e.g. projectile, bilious, bloody, etc.)
- pattern of emesis (e.g. association with feeds, cyclic, morning, prolonged, positional, etc.)
- associated symptoms (e.g. anorexia, diarrhea, abdominal pain, hematochezia, fever, headache etc.)
- red flags: bilious or bloody emesis, projectile vomit, abdominal distension and tenderness, high fever, signs of dehydration, worse when lying down
- remember that vomiting without diarrhea is not always gastroenteritis
  - post-tussive vomiting is also common with coughing fits in children

Physical
- vital signs to determine clinical status and hydration state
- abdominal examination for evidence of obstruction or focal tenderness
- neurologic assessment for signs of increased ICP

Investigations
- if child appears well and no worrisome features, often investigation is not required
- CBC, electrolytes, BUN, Cr, amylase, lipase, glucose, liver enzymes, urinalysis done routinely
- in sick child, add: ESR, venous blood gases, C&S (blood, stool), imaging (x-ray, U/S)

Table 20. Common Differential Diagnosis, Associated Findings, and Diagnostic Approach Based on Age

Cause	Suggestive Findings	Diagnostic Approach
NEONATES – NON-BILIOUS		
Tracheoesophageal Fistula	Excessive secretions soon after birth (e.g. drooling, choking, respiratory distress/ pneumonia), inability to feed, cyanosis (esp with feeds), emesis	Inability to advance NG tube, CXR, upper GI series with water-soluble contrast
Pyloric Stenosis	Projectile non-bilious emesis within 30 min after feeding, fatigue, dehydrated, palpable "olive" in RUQ, decreased stools, hunger	CBC, electrolytes, Cr, BUN, ABG (hypokalemic, hypochloremic metabolic alkalosis), U/S of pylorus, upper GI study (if U/S nondiagnostic)
GERD	Fussiness after feeds, spit ups, arching of back, poor weight gain	Empiric trial of acid suppression, pH monitoring study, upper GI study, endoscopy
Sepsis	Fever, lethargy, tachycardia, tachypnea, widening pulse pressure	CBC, PT/PTT, electrolytes, Cr, BUN, LFTs, bilirubin, lactate, urinalysis, cultures (blood, urine, CSF), CXR
Inborn Error of Metabolism	Poor feeding, FTT, jaundice, hepatosplenomegaly, cardiomyopathy, dysmorphia, developmental delay, neurologic manifestations	Electrolytes, ABG (hyponatremic, hyperkalemic metabolic acidosis), lactate, ammonia, LFTs, BUN, Cr, serum glucose, bilirubin, PT/PTT, CBC
NEONATES – BILIOUS		
Intestinal Obstruction – Malrotation with Volvulus, Meconium Ileus, etc.	Bilious emesis, abdominal distension, pain, bloody stool, shock	AXR, upper GI series, contrast enema
Duodenal Atresia/Stenosis	Bilious emesis, abdominal distension, often seen in DS, jaundice, polyhydramnios during pregnancy, hypokalemic, hypochloremic metabolic alkalosis	AXR, upper GI series ('double bubble' sign)
Hirschsprung's Disease	Bilious emesis, abdominal distension, pain, failure to pass stool	AXR, contrast enema, rectal biopsy
Necrotizing Enterocolitis	Premature neonate, bilious emesis, bloody stools, abdominal distension, intolerance of feeds, electrolytes, Cr, BUN, blood culture	AXR, CBC, electrolytes, Cr, BUN, blood culture
CHILDREN AND ADOLESCENTS		
Acute Viral Gastroenteritis	Diarrhea, fever, abdominal discomfort, myalgia, sick contact, recent travel	Generally clinical diagnosis; if severe: CBC, electrolytes, stool studies
Appendicitis	Periumbilical discomfort that later localizes to RLQ, fever, anorexia	Abdominal U/S
Intussusception	Colicky progressive abdominal pain, drawing of legs up to chest, lethargy, bloody "red currant jelly" stool (Triad)	Abdominal U/S, AXR (rule out other etiologies and perforation)
Non-GI Infection (e.g. Meningitis, pyelonephritis, acute otitis media)	Fever, localized findings depending on cause	Cultures (CSF, blood, urine), brain imaging, CXR
Increased ICP	Nocturnal wakening, progressive recurrent headache worse with Valsalva, focal neurologic deficits, gait disturbance	Brain CT without contrast Therapeutic LP in idiopathic intracranial HTN
Toxic Ingestion	Findings vary by substance - toxidrome, often a history of ingestion	Qualitative and sometimes quantitative levels (urine, blood)
Pregnancy	Amenorrhea, morning sickness, bloating, breast tenderness	Urine β-hCG
Cyclic Vomiting	At least 3 self-limited episodes of vomiting lasting 12 h, 7 d between episodes, no organic cause of vomiting	Diagnosis of exclusion

Management
- rehydration (see *Fluids and Electrolytes*, P38)
- treat underlying cause and correct metabolic/electrolyte abnormalities
- antiemetic drugs can be used in older infants, children and adolescents with severe vomiting: ondansetron, promethazine, prochlorperazine, metoclopramide
- not recommended when unknown etiology or anatomic abnormalities

Gastroesophageal Reflux

Epidemiology
- extremely common in infancy (up to 50%) but rarely causes pathology (i.e. GERD)

Clinical Features
- passage of stomach contents into esophagus, may cause regurgitation or vomiting typically soon after feeding, non-bilious, rarely contains blood, small volume (<30 mL)
  - should suspect GERD, defined as when gastroesophageal reflux causes troublesome symptoms/complications (i.e. when gastroesophageal reflux causes disease/complications):
    - infant: poor weight gain, irritability, sleep disturbance, respiratory symptoms (coughing, choking, wheezing)
    - older child/adolescent: abdominal pain/heartburn, dysphagia, asthma, recurrent pneumonia/upper respiratory infections (if aspirating), recurrent otitis media, upper airway symptoms (chronic cough, hoarseness), dental erosions

Investigations
- thriving baby requires no investigation
- GERD generally can be a clinical diagnosis, diagnostic investigations rarely done but may include:
  - upper GI series – assesses anatomy and motility disorder
  - esophageal pH – assess frequency and duration of acid exposure, not a definitive diagnostic test
  - upper endoscopy and esophageal biopsy – rule out other conditions that mimic GERD symptoms (e.g. eosinophilic esophagitis), assess GERD-related esophageal injury
- warning signs of associated disorders requiring further investigations: bilious vomiting, GI tract bleeding, forceful vomiting, fever, lethargy, hepatosplenomegaly, bulging fontanelle, micro/macrocephaly, seizures, abdominal tenderness/distension, suspected genetic, metabolic syndrome, or chronic disease

Management
- conservative (infant): thickened feeds, frequent and smaller feeds, elevation of head, changing formula to hydrolyzed protein or amino acid based formula, starting solid foods if age appropriate
  - breastfeeding infants – sequential elimination diet by mother including milk, beef, soy, and egg
- conservative (older children/adolescent): same as adult management
- medical
  - short-term parenteral feeding to enhance weight gain
  - H2-blocker, PPI: decreases gastric acidity, decreases esophageal irritation
    - recommended when failure of conservative measures, moderate – severe disease or biopsy-proven esophagitis
  - domperidone, metoclopramide: generally not recommended for GERD, reserved when concurrent gastroparesis
    - acid-suppressants or motility agents not recommended for infants with uncomplicated reflux
- interventional (indicated for failure of medical therapy):
  - Nissen fundoplication
  - insertion of gastrojejunal tube for post-pyloric feeds

Complications
- esophagitis, oral feeding aversion, poor weight gain, aspiration, strictures, Barrett's esophagus

Tracheoesophageal Fistula

- see General and Thoracic Surgery, GS75

Pyloric Stenosis

- see General and Thoracic Surgery, GS73

Duodenal Atresia

- see General and Thoracic Surgery, GS74

Malrotation of the Intestine

- see General and Thoracic Surgery, GS73

Diarrhea

- definition of diarrhea varies with diet and age (stool normalcy difficult to define in children)
- infants ➔ increase in stool frequency to twice as often per day; older children ➔ 3+ loose or watery stools/d
- duration: acute: <2 wk; chronic: >2 wk

Diarrhea is defined as an increase in frequency and/or decreased consistency of stools compared to normal

Normal stool volume
Infants: 5-10 g/kg/d
Children: 200 g/d

Pathophysiology
- osmotic: due to non-absorbable solutes in GI tract (e.g. lactose intolerance)
- secretory: increased secretion of Cl^- ions and water in intestinal lumen (e.g. bacterial toxin)
- malabsorption: less time for absorption due to increased motility or less villi to absorb (e.g. short bowel syndrome)

History
- frequency, duration, quality of diarrhea
- associated symptoms (e.g. fever, vomiting, abdominal pain, hematochezia)
- recent antibiotic use or travel
- elements of diet

Diarrhea Red Flags
Bloody stool, fever, petechiae or purpura, signs of severe dehydration, weight loss/FTT

Physical
- vital signs and complete examination to determine clinical status and hydration state

Common Antibiotics that Can Lead to *C. difficile* Infection
- Fluoroquinolones
- Clindamycin
- Penicillin (broad spectrum)
- Cephalosporins (broad spectrum)

Investigations
- acute diarrhea (well child with non-bloody diarrhea often requires no further investigations)
  - stool for C&S, O&P, electron microscopy for viruses, *C. difficile* toxin, microscopy (leukocytes suggestive of invading pathogen), blood and urine cultures, CBC, electrolytes, BUN, Cr, glucose, abdominal imaging
- chronic diarrhea
  - serial heights, weights, growth percentiles
  - if child growing well and thriving, workup is limited (stool cultures as above, stool reducing substances)
  - red flags: poor growth, chronic rash, other serious infections, hospitalizations for dehydration (require full workup)
    - stool: consistency, pH, reducing substances, microscopy, occult blood, O&P, C&S, *C. difficile* toxin, 3 d fecal fat, α-1-antitrypsin clearance, fecal elastase
    - urinalysis, urine culture
    - CBC, differential, ESR/CRP, smear, electrolytes, total protein, albumin, carotene, Ca^{2+}, PO_4^{3-}, Mg^{2+}, Fe, ferritin, folate, fat-soluble vitamins, PTT, INR
    - sweat chloride, celiac screen, thyroid function tests, urine VMA and HVA, HIV test, lead levels
    - CXR, upper GI series and follow-through
    - specialized tests: endoscopy, small bowel biopsy

Differential Diagnosis

Table 21. Differential Diagnosis of Diarrhea

	Infectious			Non-infectious
Acute	**Viral** Rotavirus Norwalk Enteric adenovirus	**Bacterial** *Salmonella* *Campylobacter* *Shigella* Pathogenic *E. coli* *Yersinia* *C. difficile*	**Parasitic** *Giardia lamblia* *Entamoeba histolytica*	Antibiotic-induced Non-specific: associated with systemic infection Hirschsprung's disease Toxin ingestion Primary disaccharidase deficiency Intussusception
Chronic	**0 – 3 mo**	**3 mo – 3 yr**	**3 – 18 yr**	**Uncommon**
No FTT	GI infection	GI infection Toddler's diarrhea	GI infection Lactase deficiency Irritable bowel syndrome	Drug-induced Chronic constipation UTI
FTT	Disaccharidase deficiency, food protein induced allergic proctocolitis (FPIAP) CF Hirschsprung's Disease	Celiac disease	IBD Endocrine (thyrotoxicosis, Addison's) Neoplastic (pheochromocytoma, lymphoma)	Short bowel syndrome Shwachman-Diamond syndrome HIV Autoimmune Enteropathy Eosinophilic Gastroenteritis

Gastroenteritis

History
- non-specific: diarrhea, vomiting, fever, anorexia, headache, myalgias, abdominal cramps
- viral causes most common, bacterial and parasitic agents more common in older children (2-4 yr)
- recent infectious contacts: symptoms usually begin 24-48 h after exposure

Physical Exam
- febrile
- dehydrated: must assess extent (see *Approach to Infant/Child with Dehydration*, P38)

Investigations
- not usually necessary in young children
- CBC, electrolytes, and stool studies may be indicated in severe cases, if IV hydration required or atypical presentation
- stool analysis: leukocytes/erythrocytes suggests bacterial or parasitic etiology

Complications
- viral gastroenteritis usually self-limiting (lasts 3-7 d in most cases)
- adverse effects related to hypovolemia, shock, tissue acidosis, and rapid onset and over-correction of electrolyte imbalances
- death in severe dehydration (rare in developed countries)

Table 22. Gastroenteritis

	Viral Infection	Bacterial Infection
Etiology	Most common cause of gastroenteritis Commonly: rotaviruses (most common), enteric adenovirus, norovirus (typically older children)	*Salmonella, Campylobacter, Shigella,* pathogenic *E. coli, Yersinia, C. difficile*
Clinical Features	Associated with URTIs Resolves in 3-7 d Slight fever, malaise, vomiting, vague abdominal pain	Severe abdominal pain High fever Bloody diarrhea
Risk Factors	Daycare, young age, sick contacts, immunocompromised Bacterial infection: travel, poorly cooked meat, poorly refrigerated foods, antibiotics	
Management	Prevention and treatment of dehydration most important (see *Approach to Infant/Child with Dehydration*, P38) Early refeeding advisable, with age-appropriate diet upon completion of rehydration Ondansetron for suspected gastroenteritis with mild to moderate dehydration or failed ORT and significant vomiting Antibiotic or antiparasitic therapy when indicated, antidiarrheal medications not indicated Notify Public Health authorities if appropriate Promote regular hand-washing and return to school 24 h after last diarrheal episode to prevent transmission Rotavirus vaccine	

Toddler's Diarrhea

Epidemiology
- most common cause of chronic diarrhea during infancy
- onset between 6-36 mo of age, resolves spontaneously between 2-4 yr

Clinical Features
- diagnosis of exclusion in thriving child
- 4-6 bowel movements per day
- diet history (e.g. excess juice intake overwhelms small bowel resulting in disaccharide malabsorption)
- stool may contain undigested food particles
- excoriated diaper rash

Management
- reassurance that it is self-limiting
- **4F**s (adequate **F**ibre, normal **F**luid intake, 35-40% **F**at, discourage excess **F**ruit juice)

Lactase Deficiency (Lactose Intolerance)

Clinical Features
- chronic, watery diarrhea and abdominal pain, bloating associated with dairy intake
- primary lactose intolerance: crampy abdominal pain with loose stool (older children, more common in East Asian and African descent)
- secondary lactose intolerance: older infant, persistent diarrhea (decreased lactase production post viral/bacterial infection, celiac disease, or IBD)

Diagnosis
- investigations usually not needed, trial of lactose-free diet
- symptom assessment with validated questionnaire after oral lactose load
- positive breath hydrogen test if >6 yr after oral lactose load with simultaneous symptom assessment
- tests for lactase deficiency: small bowel biopsy, genetic testing
  - demonstration of lactose malabsorption should be combined with assessment of intolerance symptoms

Management
- lactose-free diet
- lactase-containing tablets/capsules/drops (e.g. Lacteeze®, Lactaid®)

Irritable Bowel Syndrome

- see Gastroenterology, G26

Celiac Disease

Celiac disease is associated with an increased prevalence of IgA deficiency. Since tTG is an IgA-detecting test, you must order an accompanying IgA level

A Celiac disease diet must avoid gluten present in "**BROW**" foods
Barley
Rye
Oats (controversial)
Wheat

- see Gastroenterology, G21
- in children: presents at any age, often 6-24 mo with the introduction of gluten in the diet
- poor weight gain, poor appetite, irritability, apathy, rickets, wasted muscles, flat buttocks, rarely distended abdomen
- GI symptoms: N/V, edema, anemia, abdominal pain, diarrhea
- non-GI manifestations: iron-deficiency anemia, dermatitis herpetiformis, dental enamel hypoplasia, osteopenia/osteoporosis, short stature, delayed puberty, behavioural changes
- associated with other autoimmune disorders (e.g. T1DM, thyroid disease)

Cow's Milk Allergy

Pathophysiology
- cow's milk allergy (CMA) may be either an IgE-mediated reaction or a non-IgE mediated reaction, which is further classified as a food protein-induced allergic proctocolitis (FPIAP), food protein-induced enterocolitis syndrome (FPIES), or food-protein-induced enteropathy

Clinical Features
- IgE-mediated CMA reactions occur within hours of exposure and are present on the skin (i.e. urticarial, pruritus, etc.), upper and lower resp tract symptoms (i.e. wheeze, cough, etc.), gastrointestinal symptoms (i.e. abdominal pain, nausea/vomiting, diarrhea, etc.)
- non-IgE-mediated CMA reactions occur hours following ingestion, within few mo, presents with:
  - FPIAP: mild diarrhea, small amounts of bloody stools (common in young infant)
  - FPIES: severe vomiting, and diarrhea, anemia, hematochezia
  - food protein-induced enteropathy: FTT, chronic diarrhea, hypoalbuminemia
- up to 50% of children intolerant to cow's milk may be intolerant to soy protein as well

Investigations
- food challenge (gold standard), skin prick test, serum measurement of allergen-specific IgE, patch testing

Management
- IgE-mediated CMA: stop exposure, epinephrine for acute anaphylactic reactions
- non-IgE-mediated CMA: stop, reintroduce milk at 6-8 mo, vast majority (>90%) will outgrow by 1 yr
- casein hydrolysate formula (Nutramigen®, Pregestimil®) or mother may sequentially remove cow's milk protein, all bovine protein, soy protein, legumes (7 d washout), and continue breastfeeding (with adequate calcium and vitamin D intake)

Inflammatory Bowel Disease

- see Gastroenterology, G22

Cystic Fibrosis

- see Respirology, R12

Constipation

- decreased stool frequency (<3 stools/wk) and/or stool fluidity (hard, pellet-like)

FUNCTIONAL CONSTIPATION
- 99% of cases of constipation
- Rome III criteria
  - ≥2 of the following for at least 1 mo:
    - ≤2 defecations/wk
    - history of excessive stool retention
    - history of large-diameter stools
    - history of painful or hard bowel movements
  - in toilet-trained children, the following additional criteria may be used:
    - at least one episode/wk of incontinence after the acquisition of toileting skills
    - history of large-diameter stools that may obstruct toilet

Pathophysiology
- lack of fibre in diet or change in diet, poor fluid intake, behavioural
  - infants: often occurs when introducing cow's milk after breast milk due to high fat and solute content, lower water content
  - toddlers/older children: can occur during toilet training, starting school, or due to pain on defecation, leading to withholding of stool
  - adolescents: often related to school stressors, anxiety/eating disorders

Management
- education: explanation of mechanism of functional constipation for parents/older children
- clean out: PEG 3350 flakes (1-1.5 g/kg/d, max 100 g/d), picosalax, PEGlyte®
- maintenance: adequate fluid intake (if <6 mo, 150 mL/kg/d), adequate dietary fibre (fruit, vegetables, whole grains), stool softening (PEG 3350, mineral oil), appropriate toilet training technique (dedicated time for defecation: 3-10 min, 1-2 x/d)
- children should be treated for at least 3-6 mo, and should not be weaned from maintenance therapy until they are having regular bowel movements without difficulty
- regular follow-up with ongoing support and encouragement is essential

Complications
- pain retention cycle: anal fissures and pain from withholding passing stool, chronic dilatation ± overflow incontinence

HIRSCHSPRUNG'S DISEASE (Congenital Aganglionic Megacolon)
- see General and Thoracic Surgery, GS74

OTHER ORGANIC DISORDERS CAUSING CONSTIPATION
- endocrine: hypothyroidism, DM, hypercalcemia
- neurologic: spinal cord abnormalities/trauma, NF
- anatomic: bowel obstruction, anus (imperforate, atresia, stenosis, anteriorly displaced)
- drugs: lead, chemotherapy, opioids
- celiac disease
- others

Abdominal Pain

ACUTE ABDOMINAL PAIN

History
- description of pain (location, radiation, duration, constant vs. colicky, relation to meals)
- associated symptoms: N/V, diarrhea, fever

Physical Exam
- abdominal exam, rectal exam, rash

Investigations
- may include CBC, differential, liver enzymes, lipase, bilirubin, creatinine, CRP, glucose, blood gas urinalysis to rule out UTI, β-HCG, abdominal, pelvic, and/or testicular imaging

Table 23. Differential Diagnosis of Acute Abdominal Pain

Gastrointestinal	Hepatobiliary Tract	Genitourinary	Hematologic	Metabolic	Drug and Toxins	Pulmonary	Miscellaneous
Gastroenteritis	Hepatitis	UTI	Sickle cell crisis	Diabetic ketoacidosis	Erythromycin	Pneumonia	Functional pain
Appendicitis	Cholecystitis	Urinary calculi	Henoch-Schönlein purpura	Hypoglycemia Porphyria	Salicylates	Diaphragmatic pleurisy	Infantile colic
Mesenteric adenitis	Cholelithiasis	Dysmenorrhea	Hemolytic uremic syndrome		Lead poisoning		Pharyngitis
Constipation	Spleen – infarction, rupture	Mittelschmerz			Venoms		Angioneurotic edema
Ileus	Pancreatitis	PID					Mediterranean fever
Abdominal trauma		Threatened abortion					Neoplasms (i.e. Wilms' tumour, neuroblastoma, etc.)
Intestinal obstruction (incarcerated hernia, intussusception, volvulus)		Ectopic pregnancy					
Peritonitis		Nephrolithiasis					
Peptic ulcer		Testicular torsion					
Meckel's diverticulum		Ovarian torsion					
IBS		Ruptured ovarian cyst					
Food poisoning		Endometriosis					
Lactose intolerance		Hematocolpos					

APPENDICITIS

- see General and Thoracic Surgery, GS35
- most common cause of acute abdomen after age 5
- clinical features: low grade fever, abdominal pain, anorexia, N/V (after onset of pain), peritoneal signs (generalized peritonitis is a common presentation in infants/young children)
- treatment: surgical
- complications: perforation (common in young children), abscess

INTUSSUSCEPTION

- telescoping of segment of bowel into distal segment causing ischemia and necrosis

Epidemiology

- 90% idiopathic, children with CF or GJ tube at significantly increased risk; M:F=3:2
- 60% <12 mo, 80-90% before age 2

Pathophysiology

- usual site: ileocecal junction; jejunum in children with GJ tubes
- lead point of telescoping segment may be swollen Peyer's patches, Meckel's diverticulum, polyp, malignancy, HSP, structural abnormalities

Clinical Features

- "classic triad" (<15% patients) - abdominal pain, vomiting, red currant jelly stools
- often preceded by URTI
- sudden onset of recurrent, paroxysmal, severe periumbilical pain associated with inconsolable crying and raising legs toward abdomen with pain-free intervals
- later vomiting (may be bilious) and rectal bleeding (late finding)
- shock and dehydration; lethargy may be only presenting symptom

Diagnosis

- air enema: both diagnostic and therapeutic
- AXR, U/S

Management

- air or saline/contrast enema can be therapeutic (reduces intussusception in 75% of cases), reduction under hydrostatic pressure, surgery rarely needed
- recurrence rate 10-15%, need to consider pathologic lead point

Chronic Abdominal Pain

Epidemiology
- prevalence: 10% of school children (peak at 8-10 yr), F>M

Etiology
- organic (<10%)
  - gastrointestinal
    - constipation (cause vs. effect), infectious
    - IBD, esophagitis, peptic ulcer disease, lactose intolerance
    - anatomic anomalies, masses
    - pancreatic, hepatobiliary
    - celiac disease
  - genitourinary causes: recurrent UTI, nephrolithiasis, chronic PID, Mittelschmerz
  - neoplastic
- functional abdominal pain (90%): can be diagnosed when there are no alarming signs or symptoms, physical exam is normal; no further testing is required, unless high suspicion for organic cause
  - alarming symptoms include involuntary weight loss, deceleration of linear growth, GI blood loss, significant vomiting, chronic severe diarrhea, persistent upper or right lower quadrant pain, unexplained fever, family history of IBD
  - can be further subclassified into functional dyspepsia (pain in upper abdomen), irritable bowel syndrome (alternating bowel movements), abdominal migraine (paroxysmal abdominal pain, associated with anorexia, nausea, vomiting, pallor), functional abdominal pain syndrome

Clinical Features (Functional Abdominal Pain)
- clustering episodes of vague, crampy periumbilical/epigastric pain, vivid pain description
- seldom awakens child from sleep, less common on weekends
- aggravated by exercise, alleviated by rest
- psychological factors related to onset and/or maintenance of pain, school avoidance
- psychiatric comorbidity: anxiety, somatoform, mood, learning disorders, sexual abuse, eating disorders, elimination disorders
- diagnosis of exclusion

Investigations (Functional Abdominal Pain)
- fecal studies (calprotectin, occult blood) and others based on clinical suspicion (e.g. CBC, ESR, urinalysis, imaging etc.)

Management (Functional Abdominal Pain)
- continue to attend school
- manage any emotional or family problems, counselling, CBT
- trial of high fibre diet, or trial of lactose-free diet may be considered
  - medication rarely used, should be for symptom relief – acid reduction therapy for dyspepsia, antispasmodic agents, smooth muscle relaxants for pain, non stimulating laxatives or antidiarrheals for altered bowel pattern
- possible role for amitriptyline or gabapentin
- reassurance

Prognosis (Functional Abdominal Pain)
- pain resolves in 30-50% of children within 2-6 wk of diagnosis
- 30-50% of children with functional abdominal pain have functional pain as adults (e.g. IBS)

Chronic Abdominal Pain

Rule of 3s
3 episodes of severe pain
Child >**3** y/o
Over **3** mo period

Red Flags for Organic Etiology of Chronic Abdominal Pain
- Age <5
- Fever
- Localizes pain away from midline
- Anemia
- Evidence of GI blood loss
- Rash
- Pain wakes child at night
- Travel history
- Prominent vomiting, diarrhea
- Weight loss or failure to gain weight
- Deceleration in linear growth
- Joint pain
- Family history of IBD
- Abnormal or unexplained physical exam findings

Abdominal Mass

Table 24. Differential Diagnosis for Abdominal Mass

	Non-malignant	Malignant
Renal (note: 50% of abdominal masses in newborns are renal in origin)	Hydronephrosis Polycystic kidney disease Hamartoma	Nephroblastoma (Wilms' tumour) Renal cell carcinoma
Adrenal		Neuroblastoma
Ovarian	Ovarian cysts	Ovarian tumours
Other	Hepatomegaly/splenomegaly Pyloric stenosis Abdominal hernia Teratoma Fecal impaction	Lymphoma Rhabdomyosarcoma Retroperitoneal sarcoma

Table 25. Renal Etiologies of an Abdominal Mass

Abdominal Mass	Benign or Malignant	Clinical Features	Management
Hydronephrosis	Benign	Usually asymptomatic Urinary tract obstruction Vesicoureteral reflux	Genetic counselling Unilateral hydronephrosis >4 mm in second trimester, a follow-up US scan in third trimester is performed Persistent hydronephrosis >10 mm require postnatal evaluation
Polycystic Kidney Disease	Benign	Progressive renal failure, hypertension, urinary tract infection, concentrating defects, hematuria, nephrolithiasis, flank pain	BP control with ACE inhibitors Dietary sodium restrictions Statins Vasopressin receptor antagonists
Hamartoma	Benign	Asymptomatic abdominal swelling Abdominal pain (30-40%) Hematuria (12-25%) Fever and hypertension (25%)	Surgery, chemotherapy, radiation
Wilm's Tumour	Malignant	Asymptomatic abdominal swelling Abdominal pain (30-40%) Hematuria (12-25%) Fever and hypertension (25%)	Surgery, chemotherapy, radiation
Renal Cell Carcinoma	Malignant	Classic triad of flank pain, hematuria and palpable abdominal renal mass	For localized RCC, surgery is curative For advanced RCC, immunotherapy and radiation

Upper Gastrointestinal Bleeding

- see Gastroenterology, G28

Lower Gastrointestinal Bleeding

- see Gastroenterology, G30

Etiology

- acute
  - infectious (bacterial, parasitic)
  - antibiotic-induced (*C. difficile*)
  - NEC in preterm infants
  - anatomic
  - malrotation/volvulus, intussusception
  - Hirschsprung disease
  - Meckel's diverticulitis
  - anal fissures, hemorrhoids
  - vascular/hematologic
  - HSP
  - HUS
  - coagulopathy

- chronic
  - anal fissures (most common)
  - infectious colitis
  - IBD
  - FPIAP
  - allergic (milk protein)
  - structural
  - polyps (most are hamartomas)
  - neoplasms (rare)
  - coagulopathy

Physical Exam
- hemodynamic status, evidence of poor growth, fever
- anal and rectal exam: tags, fissures, anal fistulas, polyps, foreign body, blood per rectum
- stool appearance
- NG aspirate
- lower GI bleed may present as melena (if it involves the small bowel) or hematochezia

Investigations
- stool cultures (C&S, *C. difficile* toxin)
- urinalysis and microscopy
- CBC, smear, differential, ESR, CRP, electrolytes, urea, Cr, INR, PTT, albumin, iron studies, amoeba titers
- radiologic investigations
- Meckel's radionuclide scan
- Colonoscopy

Management
- acute stabilization: ABCs, volume and blood replacement, bowel rest (NPO, NG tube)
- treatment dictated by etiology
- once stable, endoscopy and/or surgery as indicated

Genetics, Dysmorphisms, and Metabolism

- see Medical Genetics, MG4

Hematology

Approach to Anemia

CLASSIFICATION
- mechanism: decreased production (inadequate reticulocyte response) vs. increased destruction or loss (adequate reticulocyte response)
- in the context of anemia, a normal reticulocyte count is inappropriate

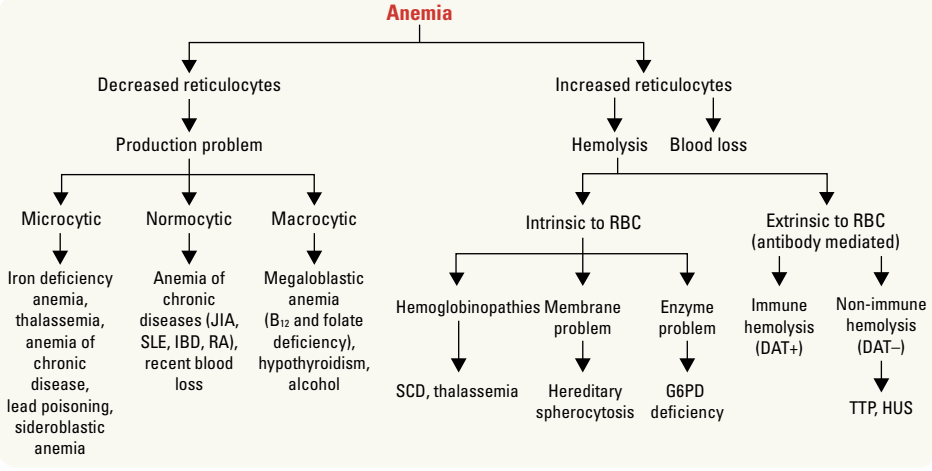

Figure 11. Approach to anemia

Normal Hb Values by Age

Age	Hb Range (g/L)
Newborn	137-201
2 wk	130-200
3 mo	95-145
6 mo-6 yr	105-140
7-12 yr	110-160
Adult female	120-160
Adult male	140-180

Physiologic Anemia

- high Hb (>170 g/L) and reticulocyte count at birth is caused by a relatively hypoxic environment in utero and increased erythropoietin levels
- after birth, levels start to fall due to shorter fetal RBC lifespan, decreased RBC production (during first 6-8 wk of life, there is virtually no erythropoiesis due to new O_2 rich environment), and increasing blood volume secondary to growth
- lowest levels about 100 g/L at 8-12 wk (earlier and more exaggerated in premature infants); levels rise spontaneously with activation of erythropoiesis
  - red flags suggesting non-physiologic anemia may include Hb level lower than expected with physiologic anemia, signs of hemolysis or symptoms of anemia
- usually no treatment required

MCV in childhood varies with age
Rule of thumb: lower normal limit of MCV = 70 + age (yr) until 80 fL (adult standard)

Ferritin is an acute phase reactant, therefore, normal or high ferritin does not exclude iron deficiency anemia during an infection

Iron Deficiency Anemia

- most common cause of childhood anemia
- full term infants exhaust iron reserves by age 6 mo
- premature infants have lower reserves, therefore exhausted by age 2-3 mo
- common diagnosis between 6 mo-3 yr and 11-17 yr due to periods of rapid growth and increased iron requirements; adolescents also have poor diets and menstrual losses

Iron deficiency is rare in children <6 mo in the absence of blood loss or prematurity

Etiology
- children at risk (premature, maternal iron deficiency, LBW, low socioeconomic status (SES), etc.)
- dietary risk factors: cow's milk in first year of life
  - age >6 mo: <2 servings/d of iron-fortified cereal, red meat, or legumes
  - age <12 mo: use of low-iron formula (<10 mg/L); primary diet of cow, goat, or soy milk
  - age 1-5 yr: >500 ml/d of non-iron fortified milk
- malabsorption syndrome (i.e. celiac disease, Crohn's disease, short bowel syndrome, etc.)
- blood loss
  - iatrogenic: repeated blood sampling (especially in hospitalized neonates)
  - allergic: cow's milk protein-induced colitis
  - gastrointestinal: IBD

Clinical Features
- usually asymptomatic until marked anemia
- symptoms may include: pallor, fatigue, pica (eating non-food materials), tachycardia, systolic murmur, angular cheilitis, koilonychia (spoon nails)

Investigations
- CBC: low Hb, MCV, and MCH, reticulocyte count normal or high (absolute number low)
- Mentzer index (MCV/RBC) can help distinguish iron deficiency anemia from thalassemia
  - ratio <13 suggests thalassemia
  - ratio >13 suggests iron deficiency
- blood smear: hypochromic, microcytic RBCs, pencil shaped cells, poikilocytosis
- iron studies: low ferritin, other (low iron, high total iron binding capacity, high transferrin, low transferrin saturation)

Prevention
- breastfed term infants: begin iron supplementation (1 mg/kg/d) at 4-6 mo, continuing until able to eat ≥2 feeds/d of iron-rich foods
- non-breastfed (<50% of diet) term infants: give iron-fortified formula from birth
- premature infants: give iron supplements beginning at 2 wk (2-4 mg/kg/d, max 15 mg), continue at least 2 mg/k/d until 1 yr
- no cow's milk until 12 mo, early introduction of red meat and iron-rich vegetables: total daily iron should be 11 mg (ages 6-12 mo), 7 mg (ages 1-3 yr)
- consider screening Hb levels in infants not receiving iron-fortified formula at 9-12 mo, and earlier if other risk factors present

Management
- encourage diverse, balanced diet, limit homogenized milk to 500 ml/d
- oral iron therapy: 4-6 mg/kg/d elemental iron, divided BID to TID, for 3-6 mo to replenish iron stores
  - increased reticulocyte count in 2-3 d (peaks day 5-7)
  - increased hemoglobin in 4-30 d
  - repletion of iron stores in 1-3 mo
  - repeat hemoglobin levels after 1 mo of treatment
- poor response to oral iron therapy: non-adherence, medication intolerance, ongoing blood loss, IBD, celiac disease, incorrect diagnosis

Complications
- can cause irreversible effects on development if untreated (behavioural and intellectual deficiencies)
- angular cheilitis, glossitis, koilonychia (spoon nails)

Vitamin K Deficiency

Etiology
- most commonly in infants <6 mo due to hepatic immaturity not efficiently utilizing vitamin K (in preterm infants), having poor vitamin K stores, and low vitamin K content in milk, leading to vitamin K deficiency bleeding (VKDB) previously known as hemorrhagic disease of the newborn (HDNB)
- non-classic presentation acquired later in life, often in association with chronic malabsorption (i.e. CF, celiac disease, IBD, biliary atresia, primary biliary cholangitis, primary sclerosing cholangitis, etc.), liver failure, medications (i.e. antibiotics)
  - risk factors for non-classic presentation: maternal medication (i.e. antiepileptic drugs), chronic malabsorption, no prophylaxis

Clinical Features
- VKDB due to relative deficiencies of vitamin K-dependent coagulation factors
  - generalized bleeding; cutaneous bleeding, mucosal bleeding (GI, umbilicus), and/or intracranial hemorrhage
  - early-onset (in first 24 h), classic (2 d to 7 d), and late-onset (2-12 wk up to 7 mo, high occurrence of ICH)
- acquired vitamin K deficiency symptoms may include: easy bruising, mucosal bleeding (i.e. epistaxis, GI bleed, hematuria, etc.)

Management
- VKDB managed urgently with IV/SC vitamin K (1-2 mg). If there is severe bleeding, also administer fresh frozen plasma or prothrombin complex concentrate
- prevented with vitamin K IM injection (0.5-1 mg) at birth, can also be given orally as vitamin K (doses: first feed, 1, 4, 8 wk) for breastfed, term infants but higher risk of VKDB
- bleeding due to vitamin K deficiency of other acquired etiologies managed with PO/IM/SC/IV vitamin K, with dose dependent on condition

Anemia of Chronic Disease

- see Hematology, H16

Sickle Cell Disease

- see Hematology, H21

Thalassemia

- see Hematology, H19

Hereditary Spherocytosis

- see Hematology, H24

Glucose-6-Phosphate Dehydrogenase Deficiency

- see Hematology, H24

G6PD deficiency protects against parasitism of RBCs (i.e. malaria)

Bleeding Disorders

- see Hematology, H28

Table 26. Evaluation of Abnormal Bruising/Bleeding

	PFA	PT	PTT	VIII:C	vWF	Platelets	Fibrinogen
Hemophilia A	N	N	↑	↓	N	N	N
Hemophilia B	N	N	↑	N	N	N	N
von Willebrand Disease	↑	N	N or ↑	↓	N or ↓	N	N
DIC	N or ↑	↑	↑	↓	N	↓	↓
Vitamin K Deficiency	N	↑	↑	N	N	N	N
Thrombocytopenia	↑	N	N	N	N	↓	N

DIC = disseminated intravascular coagulation; PFA = platelet function assay; VIII:C = Factor VIII coagulant activity; vWF = von Willebrand Factor

Extensive bruising in the absence of lab abnormalities: consider child maltreatment

Immune Thrombocytopenic Purpura

Definition
- ITP is isolated thrombocytopenia (platelet count <100000/microL with normal white blood cell count and hemoglobin)

Epidemiology
- most common cause of symptomatic thrombocytopenia in childhood
- peak age: 2-5 yr, M>F (slightly)
- incidence 5 in 100000 children per yr

Etiology
- caused by autoantibodies that bind to platelet membranes ➔ Fc-receptor mediated splenic uptake ➔ destruction of platelets

Clinical Features
- 60% present within 1mo after viral illness (e.g. URTI, chicken pox)
- sudden onset of petechiae, purpura, bleeding in an otherwise well child
- clinically significant bleed in only 3% (severe bleed more likely with platelet count <10) with <0.5% risk of intracranial bleed
- no lymphadenopathy, no hepatosplenomegaly
- diagnosis made in well appearing patients with mucocutaneous bleeding without other systemic symptoms or signs and lab confirmation of ITP (diagnosis of exclusion)
- labs: thrombocytopenia with normal RBC, WBC
- bone marrow aspirate only indicated if red flags on history, exam, or lab studies
- differential diagnosis: leukemia, drug-induced thrombocytopenia, HIV, infection (viral), immunodeficiency syndromes, autoimmune (SLE, autoimmune lymphoproliferative syndrome, autoimmune hemolytic anemia)

Management
- involve family in management; shared decision-making
- no or mild bleeding – watchful waiting
- moderate bleeding (i.e. severe skin manifestations with some mucosal lesions and some troublesome epistaxis or menorrhagia) – IVIg (1 g/kg) or steroids; if Rh-positive or DAT-negative can use anti-D
- severe (i.e. prolonged epistaxis, GI bleeding or intracranial hemorrhage) - immediate treatment with IV steroids and IVIg; may use tranexamic acid as adjunct therapy
- treatment with IVIg or prednisone if mucosal or internal bleeding, platelets <10, or at risk of significant bleeding (surgery, dental procedure, concomitant vasculitis, or coagulopathy)
- life-threatening bleed: additional platelet transfusion ± emergency splenectomy
- persistent (>3-12 mo) or chronic (>12 mo): re-evaluate; treat if symptoms persist
- supportive: avoid contact sports and ASA/NSAIDs

Diagnosis and Management of Typical, Newly Diagnosed Primary Immune Thrombocytopenia (ITP) of Childhood
J Pediatr Child Health 2019; 24(1):54
Recommendations
- Bone marrow examination is unnecessary in children and adolescents with the typical features of ITP
- Bone marrow examination is not necessary in children who fail IVIg therapy
- Children with no bleeding or mild bleeding (defined as skin manifestations only, such as bruising and petechiae) may be managed with observation alone regardless of platelet count
- Children with moderate bleeding may be managed with a single dose of IVIg (0.8-1 g/kg) or a short course of corticosteroids
- Children with severe bleeding (prolonged epistaxis, GI bleeding, or ICH) require immediate management with IV steroids and IVIg as well as consideration for IV tranexamic acid (IV 10mg/kg/dose every 8h)
- IVIg is used if a more rapid increase in the platelet count is desired
- Anti-D therapy is only used in Rh-positive children and not advised in children with a hemoglobin concentration that is decreased due to bleeding, or with evidence of autoimmune hemolysis

Suggestions
- Bone marrow examination is also not necessary in similar patients prior to initiation of treatment with corticosteroids or before splenectomy
- Testing for antinuclear antibodies is not necessary in the evaluation of children and adolescents with suspected ITP

Hemophilia

- see Hematology, H32

von Willebrand's Disease

- see Hematology, H31

Oncology

- cancer is the second most common cause of death after injuries in children >1 yr
- cause is rarely known, but increased risk for children with: chromosomal syndromes (e.g. Trisomy 21), cancer predisposition syndromes (e.g. Li-Fraumeni syndrome), prior malignancies, neurocutaneous syndromes, immunodeficiency syndromes, family history, exposure to radiation, chemicals, biologic agents
- leukemias are the most common type of paediatric malignancy (30%) followed by brain tumours (25%) and lymphomas (15%)
- some malignancies are more prevalent in certain age groups
  - newborns: neuroblastoma, Wilms' tumour, retinoblastoma
  - infancy and childhood: leukemia, neuroblastoma, CNS tumours, Wilms' tumour, retinoblastoma
  - adolescence: lymphoma, leukemia, gonadal tumours, germ cell tumours, thyroid cancers, melanoma, bone tumours
- unique treatment considerations in paediatrics because radiation, chemotherapy, and surgery can impact growth and development, endocrine function, and fertility
- good prognosis: treatments have led to remarkable improvements in overall survival and cure rates for many paediatric cancers (>80%)

Most common cause of acute bilateral cervical lymphadenopathy is viral illness

Lymphadenopathy

Clinical Features

- features of malignant lymphadenopathy: firm, discrete (not often), non-tender, enlarging, immobile, worrisome location (i.e. supraclavicular or generalized), abnormal imaging findings or bloodwork, constitutional symptoms
- fluctuance, warmth, or tenderness are more suggestive of benign nodes (infection)

Differential Diagnosis

- infection
  - viral: URTI, EBV, CMV, adenovirus, HIV, measles, mumps, rubella, Hep B
  - bacterial: *S. aureus*, GAS, anaerobes, *Mycobacterium* (e.g. typical and atypical TB), cat scratch disease (*Bartonella*), *Rickettsia*
  - other: fungal, protozoan
- autoimmune: rheumatoid arthritis, SLE, serum sickness
- malignancy: lymphoma, leukemia, metastatic solid tumours
- storage diseases: Niemann-Pick, Gaucher
- other: sarcoidosis, Kawasaki disease, histiocytoses

Investigations

- assess location, size, consistency, fixation, and tenderness of each node
- generalized lymphadenopathy (≥ 2 body areas)
  - CBC and differential, blood culture
  - inflammatory markers (ESR, CRP)
  - serology: EBV, CMV and others as indicated by history and physical exam (e.g. HIV, fungal, toxoplasmosis)
  - uric acid, LDH, electrolytes
  - CXR
  - tuberculin skin test
  - if indicated other blood work i.e. inflammatory panel (ANA, RF, dsDNA)
  - biopsy: late biopsy (within 4 wk) if increasing in size; or >2 cm and unclear diagnosis or no response to treatment. Do early biopsy if supraclavicular nodes, nodes >4 cm, or groups of nodes with total diameter >3 cm
- regional lymphadenopathy (1 body area)
  - period of observation if asymptomatic
  - trial of oral antibiotics
  - ultrasound
  - biopsy (especially if persistent >4 wk and/or constitutional symptoms)
  - if supraclavicular lymphadenopathy: CXR to rule out mediastinal mass

Leukemia

- see Hematology, H39

Definition

- leukemia is a cancer that starts in the bone-forming tissue (e.g. bone marrow), causing abnormal blood cell production

Epidemiology
- mean age of diagnosis 2-5 yr but can occur at any age
- heterogeneous group of diseases
  - ALL (80%)
  - AML (15%)
  - CML (<5%)
- children with DS are 15 times more likely to develop leukemia

Clinical Features
- infiltration of leukemic cells into bone marrow results in bone pain and bone marrow failure (anemia, neutropenia, thrombocytopenia)
- infiltration into tissues results in lymphadenopathy, hepatosplenomegaly, CNS manifestations, testicular disease
- fever, fatigue, weight loss, bruising, and easy bleeding
- investigations: CBC and differential, peripheral blood smear, uric acid, LDH, extended electrolytes, renal function, and blood culture
- specialized tests: BM ± lymph node biopsy, flow cytometry, cytogenetics, molecular studies
- hyperleukocytosis (total WBC >100 x 10^9/L) is a medical emergency
  - presents clinically with respiratory or neurological distress caused by hyperviscosity of blood and leukostasis
  - risk of ICH, pulmonary leukostasis syndrome, tumour lysis syndrome
  - management: fluids, allopurinol/rasburicase, fresh frozen plasma/platelets to correct thrombocytopenia, induction chemotherapy, avoid transfusing RBCs unless symptomatic (and then use very small volumes), or leukapheresis in some centres

Management
- combination chemotherapy using non-cross resistant chemotherapy agents; allogeneic stem cell transplantation for particular genetic subtypes, poorly responsive disease, or recurrent disease
- supportive care and management of treatment complications
  - febrile neutropenia: see Infectious Diseases, ID44
  - tumour lysis syndrome: see Hematology, H54

Back pain in children must always be investigated!
Unlike adults, back pain in children often points to a pathological process

Prognosis
- 80-90% 5-yr event-free survival for ALL, 50-60% 5-yr survival for AML
- patients are stratified into standard risk and high-risk based on WBC and age; other prognostic factors include presence of CNS/testicular disease, immunophenotype, cytogenetics, and initial response to therapy (most important prognostic variable)

Lymphoma

- see Hematology, H47

Epidemiology
- Hodgkin lymphoma: incidence is bimodal, peaks at ages 15-34 and >50 yr
- non-Hodgkin lymphoma: incidence peaks at 7-11 yr

Constitutional symptoms = fever, chills, night sweats, unexplained weight loss

Clinical Features
- Hodgkin lymphoma
  - most common presentation is persistent, painless, firm, rubbery, cervical or supraclavicular lymphadenopathy
  - can present as persistent cough or dyspnea (secondary to mediastinal mass) or less commonly as splenomegaly, axillary, or inguinal lymphadenopathy
  - constitutional symptoms in 30% of children
  - contiguous spread
- non-Hodgkin lymphoma
  - presents as enlarging, non-tender lymphadenopathy
  - includes most commonly mature B cell lymphoma (Burkitt, diffuse large B cell), T cell lymphoblastic, and mature T cell lymphoma (anaplastic large cell)
  - rapidly growing tumour with distant metastases (unlike adult non-Hodgkin lymphoma)
  - signs and symptoms related to disease site: most commonly abdomen (intussusception), chest (mediastinal mass), head and neck region
- investigations: CBC and differential, peripheral blood smear, extended electrolytes, uric acid, LDH, renal function, liver enzymes and function, ESR, and blood culture if concerns for infection. CXR (AP and lateral) and CT of neck/chest/abdomen/pelvis. Specialized tests: BM aspirate and biopsy ± LN biopsy, LP, PET scan

Management
- Hodgkin lymphoma
  - combination chemotherapy and radiation
  - increasing role for use of PET scanning to assess early disease response and plan therapy
- non-Hodgkin lymphoma
  - combination chemotherapy
  - no added benefit of radiation in paediatric protocols

Prognosis
- Hodgkin lymphoma: >90% 5 yr survival
- non-Hodgkin lymphoma: 75-90% 5 yr survival

Brain Tumours

- see Neurosurgery, NS11

Wilms' Tumour (Nephroblastoma)

Epidemiology
- usually diagnosed between 2-5 yr; M=F
- most common primary renal neoplasm of childhood
- 5-10% of cases both kidneys are affected (simultaneously or in sequence)

Differential Diagnosis
- hydronephrosis, polycystic kidney disease, renal cell carcinoma, neuroblastoma

Clinical Features
- 80% present with asymptomatic, unilateral abdominal mass
- may also present with HTN, gross hematuria, abdominal pain, vomiting, fever, UTI, anemia
- may have pulmonary metastases at time of diagnosis (respiratory symptoms)

Associated Congenital Abnormalities
- **WAGR** syndrome (**W**ilms' tumour, **A**niridia, **G**enitourinary anomalies, mental **R**etardation) with 11p13 deletion
- Beckwith-Wiedemann syndrome:
  - characterized by enlargement of body organs (especially tongue), hemihypertrophy, renal medullary cysts, and adrenal cytomegaly
  - also at increased risk for developing hepatoblastoma, and less commonly adrenocortical tumours, neuroblastomas, and rhabdomyosarcomas
- Denys-Drash syndrome: characterized by gonadal dysgenesis and nephropathy leading to renal failure

Management
- staging ± nephrectomy
- chemotherapy, radiation for higher stages

Prognosis
- 90% 5-yr survival
- prognostic factors include tumour histology and size, molecular and genetic markers, age

Investigations
- CBC, electrolytes, Cr, BUN, urinalysis, coagulation studies
- imaging: U/S, contrast-enhanced CT or MRI chest/abdomen/pelvis

Neuroblastoma

Epidemiology
- most common cancer occurring in first yr of life
- neural crest cell tumour arising from sympathetic tissues (neuroblasts)

Clinical Features
- can originate from any site in sympathetic nervous system, presenting as mass in neck, chest, or abdomen (most common site is adrenal gland)
- signs and symptoms of disease vary with location of tumour
  - thoracic: dyspnea, Horner's syndrome
  - abdomen: palpable mass, pain, constipation, enuresis
  - paravertebral: spinal cord compression, localized back pain, weakness
- metastases are common at presentation (>50% present with advanced stage disease):
  - usually to bone or bone marrow (presents as bone pain, limp)
  - can also present with periorbital ecchymoses, abdominal pain, emesis, fever, weight loss, anorexia, hepatomegaly, "blueberry muffin" skin nodules
- paraneoplastic: HTN, palpitations, sweating (from excessive catecholamines), diarrhea, FTT (from vasoactive intestinal peptide secretion), opsomyoclonus

Management
- depends on prognostic factors and may include combination of: surgery, radiation, chemotherapy, autologous stem cell transplantation, immunotherapy

Prognosis
- prognosis is often poor due to late detection
- good prognostic factors
  - "age and stage" are important determinants of better outcome: <18 mo, stage I, II, IV-S disease ("S" designates a "Special" classification only pertaining to infants)
  - primary site: posterior mediastinum and neck
  - more differentiated histology
  - tumour cell markers: aneuploidy, absent MYCN oncogene amplification

Investigations
- CBC, electrolytes, urinalysis, urine, catecholamine metabolites (HVA and VMA), Cr
- imaging: MRI or CT, MIBG scan
- biopsy: required for definitive diagnosis and classification
- definitive diagnosis needs one of the following:
  - unequivocal histologic diagnosis from tumour tissue
  - evidence of bone marrow metastases on aspirate biopsy with elevation of urinary/serum catecholamines or metabolites

Bone Tumours

- see Orthopaedic Surgery, OR50

Cancer Predisposition Syndromes

- suspected in cases of multiple primary neoplasms, especially early onset for cancer type and/or family history consistent with known cancer predisposition syndrome (critical to obtain family history and refer if syndrome suspected)
- cancer predisposition syndromes with paediatric onset include Li-Fraumeni syndrome (soft tissue sarcomas, osteosarcoma, CNS tumours and adrenal cortical carcinoma), hereditary retinoblastoma, and Fanconi anemia (leukemias)
- early recognition of new malignancies through surveillance limits required therapies

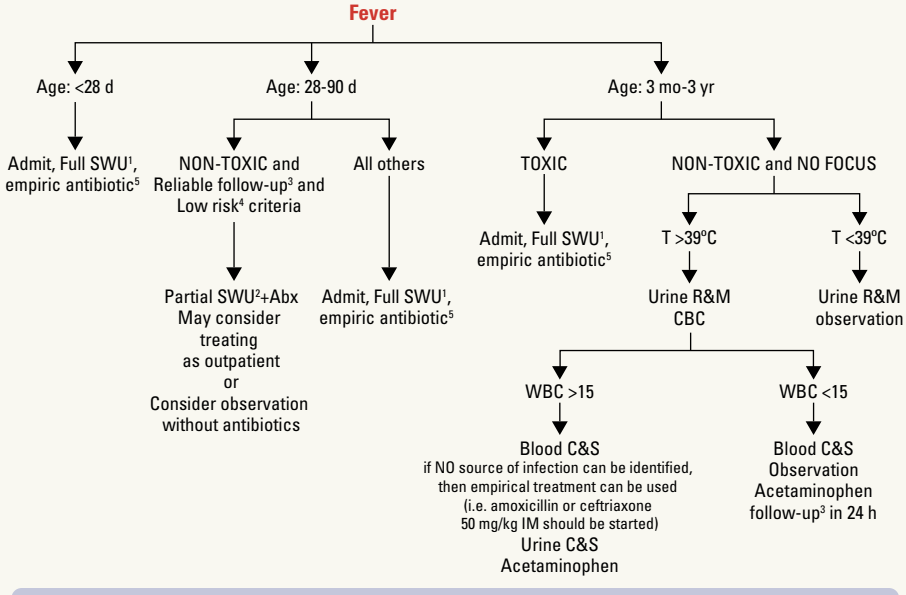
Infectious Diseases

Fever

Definition
- fever: a practical definition is >38°C/100.4°F oral or rectal
- fever without a source/focus: acute febrile illness (typically <10 d duration) with no cause of fever even after careful history and physical
- fever of unknown origin: daily or intermittent fevers for at least 2 consecutive wk of uncertain cause after careful history and physical, and initial laboratory assessment

Etiology
- infectious: anatomic approach (CNS, ears, upper and lower respiratory tract, GI, GU, skin, soft tissue, bones and joints, etc.)
- inflammatory: mainly autoimmune (Kawasaki disease, JIA, IBD, SLE, etc.)
- malignancy: childhood cancers (leukemia, lymphoma, neuroblastoma, etc.)
- miscellaneous: drugs and toxins, post-immunization, familial dysautonomia, factitious disorder, etc.

Diagnosis
- history: duration, height and pattern of fever, associated symptoms, exposures, constitutional symptoms, recent antipyretic use, ethnic or genetic background, daycare, sick contacts, travel, tick bites, age of child
- physical exam: toxic vs. non-toxic, vitals, growth, complete head-to-toe exam to identify any focus of infection
- investigations: guided by history, physical exam, and clinical suspicion



NOTES
1. SWU = Septic Workup
2. Partial SWU – blood C&S, CBC and differential, urine R&M, C&S, LP, CXR if respiratory symptoms, stool C&S if GI symptoms
3. Follow-up is crucial – if adequate follow-up is not assured, a more aggressive diagnostic and therapeutic approach may be indicated
4. Low-risk (Rochester) criteria
5. Considerable practice variation exists in terms of empiric antibiotic treatment
6. Important principles – the younger the child, the greater the difficulty to clinically assess the degree of illness

Figure 12. Approach to the febrile child

Evaluation of Neonates and Infants with Fever
- several protocols exist that attempt to identify neonates and young infants at low-risk of serious bacterial infection (e.g. Rochester Criteria)
  - such protocols are not as sensitive in the 1-28 d age group; therefore, febrile neonates should be considered high-risk regardless of clinical features and laboratory findings

Rochester Criteria – Developed to Identify Infants ≤60 d of Age with Fever at Low-risk of Serious Bacterial Infection

Clinically	Well
WBC Count	5-15 x 10^9/L
Bands	<1.5 x 10^9/L
Urinalysis	<10 WBC/high-power field
Stool (if diarrhea)	<5 WBC/high-power field
Past Health	Born >37 wk Home with/before mom No hospitalizations No prior antibiotic use No prior treatment for unexplained hyperbilirubinemia No chronic disease

Management
- admit to hospital if appropriate
- treat the source if known
- replace fluid losses (e.g. from vomiting, diarrhea); maintenance fluid needs are higher in a febrile child
- reassure parents that most fevers are benign and self-limited
- antipyretics (acetaminophen and/or ibuprofen) may be given if child is uncomfortable

Acute Otitis Media

- all of:
  1. presence of middle ear effusion
  2. presence of middle ear inflammation
  3. acute onset of symptoms of middle ear effusion and inflammation

Epidemiology
- 60-70% of children have at least 1 episode of AOM before age 3
- 6-24 mo is the most common age group
  - commonly develops within a week after a viral URI
- one third of children have had ≥3 episodes by age 3; peak incidence January to April

Etiology
- bacterial – *S. pneumoniae* (decreasing since the introduction of PCV7 and PCV13), *H. influenza, M. catarrhalis*, group A *Streptococcus* (GAS)
- less common - anaerobes (newborns) , Gram-negative enterics (infants)
- viral – more likely to spontaneously resolve

Risk Factors
- Eustachian tube related:
  - dysfunction/obstruction (URTI, allergic rhinitis, chronic rhinosinusitis, adenoid hypertrophy, barotrauma)
  - inadequate tensor veli palatini function (cleft palate)
  - genetic syndromes (DS, Crouzon, Apert)
  - cilia disruption (Kartagener's syndrome, CF)
- genetic predisposition (family history, ethnicity – First Nations peoples and Inuit, low levels of secretory IgA or persistent biofilm in middle ear)
- behavioural and environmental exposures (not breastfed or shorter duration of breastfeeding, prolonged bottle feeding, bottle feeding laying down, pacifier use, second-hand smoke exposure, crowded living conditions/daycare, sick contacts)
- immunosuppression/deficiency (chemotherapy, steroids, DM, hypogammaglobulinemia, CF)

Pathogenesis
- obstruction of Eustachian tube ➔ air absorbed in middle ear ➔ negative pressure (an irritant to middle ear mucosa) ➔ edema of mucosa with exudate/effusion ➔ infection of exudate from nasopharyngeal secretions

Clinical Features
- acute onset of symptoms
- triad of otalgia (best predictor of AOM), fever (especially in younger children), and conductive hearing loss – not all symptoms such as fever or hearing loss may be present
- rarely tinnitus, vertigo, and/or facial nerve paralysis
- otorrhea if tympanic membrane perforated
- infants/toddlers: ear-tugging (this alone is not a good indicator of pathology), hearing loss, balance disturbances (rare), irritable, poor sleeping, vomiting and diarrhea, anorexia
- otoscopy of TM: hyperemia, bulging, pus may be seen behind TM, loss of landmarks (e.g. handle and long process of malleus not visible), discolouration (hemorrhagic, grey, red, yellow)

Diagnosis
- requires middle ear effusion and signs of inflammation (most important is a bulging TM)
- accurate diagnosis of AOM is very important to prevent antibiotic overuse

Pneumococcal Conjugate Vaccines for Preventing Acute Otitis Media in Children
Cochrane DB Syst Rev 2019:CD001480
Purpose: To systematically review the use of pneumococcal conjugate vaccines in preventing AOM in children <13 years of age.
Methods: RCTs comparing the use of pneumococcal conjugate vaccines to placebo or control vaccine were included in this review.
Results: 14 studies based on 11 trials with a total of 60733 children were included in this review. During early infancy administration of licenced CRM197-PCV7 and PHiD-CV10 vaccines is associated with a large relative reduction in pneumococcal AOM. No beneficial effect was seen for all cause AOM in high-risk infants, after early infancy, or in older children with a history of respiratory illness. Mild adverse reactions (local redness or swelling, fever, pain, tenderness) were seen more commonly in the group receiving the pneumococcal conjugate vaccines compared to placebo or control vaccines. No differences in severe adverse effects were seen.

Management of Acute Otitis Media in Children Six Months of Age and Older
J Paediatr Child Health 2016;21(1):39-44
Recommendations
- Milder disease is usually due to viruses or low virulence bacteria
  - Resolves equally quickly with or without antibiotics
- Bulging tympanic membrane (especially if yellow or hemorrhagic) has a high sensitivity for AOM and is a major diagnostic criterion
  - Likely bacterial
- Perforation of the tympanic membrane with purulent discharge indicates bacterial AOM
- Indications for immediate antibiotic treatment:
  - Highly febrile (≥39°C)
  - Moderately to severely systemically ill
  - Very severe otalgia
  - Significant illness for 48 h
- Antibiotic therapy regime:
  - Amoxicillin remains the clear drug of choice
  - 10-d course for children <2 yr
  - 5-d course for children ≥2 yr
- For milder presentations, plan a reassessment at 48 h OR provide an antibiotic prescription to parents to fill if the child does not improve in 48 h

Management

- symptomatic therapy: antipyretics/analgesics (e.g. acetaminophen or ibuprofen)
- watchful waiting if criteria met
- antibiotic therapy if <6 mo or moderate-severe illness:
  - 1st line: high dose amoxicillin 75-90 mg/kg/d dosed BID x 5 d (10 d if age <2 yr, perforated TM, or recurrent AOM) (if penicillin allergic: cefuroxime-axetil, ceftriaxone)
  - 2nd line: amoxicillin-clavulanic acid, cephalosporins: cefuroxime axetil, ceftriaxone, cefaclor, cefixime
    - used when AOM unresponsive and clinical signs/symptoms persist beyond 48 h of antibiotic treatment, or for treatment of otitis-conjunctivitis syndrome
- signs of a perforated TM should always be treated with antimicrobial therapy (most commonly topical Ciprodex) and examined for complications
- prevention: parent education about risk factors, pneumococcal and influenza vaccines, surgery (e.g. tympanostomy tubes)
  - choice of surgical therapy for recurrent AOM depends on whether local factors (Eustachian tube dysfunction) are responsible (use ventilation tubes), or regional disease factors (tonsillitis, adenoid hypertrophy, sinusitis) are responsible

Complications

- extracranial: hearing loss and speech delay (secondary to persistent middle ear effusion), TM perforation, extension of suppurative process to adjacent structures (mastoiditis, petrositis, labyrinthitis), cholesteatoma, facial nerve palsy, middle ear atelectasis, ossicular necrosis, vestibular dysfunction
- intracranial: meningitis, epidural and brain abscess, subdural empyema, lateral and cavernous sinus thrombosis, carotid artery thrombosis

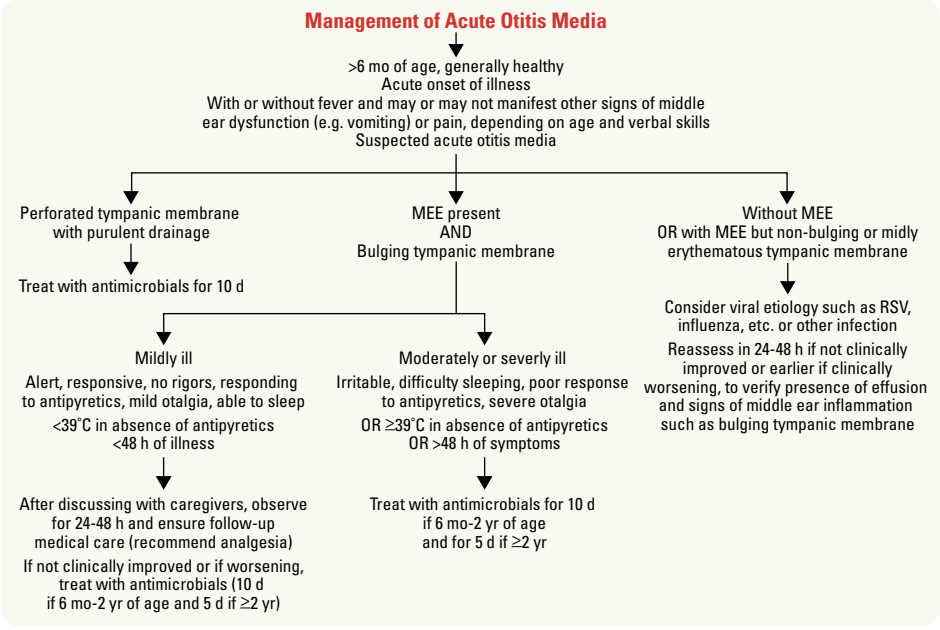


Figure 13. Management of acute otitis media
Flow diagram for the management of children with suspected and confirmed acute otitis media – from CPS statement Feb 2016

Otitis Media with Effusion

Definition
- presence of fluid in the middle ear without signs or symptoms of ear infection

Epidemiology
- most common cause of paediatric hearing loss
- not exclusively a paediatric disease
- follows AOM frequently
- middle ear effusions have been shown to persist following an episode of AOM for 1 mo in 40% of children, 2 mo in 20%, and >3 mo in 10%

Risk Factors
- same as AOM

Clinical Features
- fluctuating conductive hearing loss ± tinnitus
- fullness in ear, balance problems
- ± pain, low grade fever
- otoscopy of TM
  - discolouration – amber or dull grey
  - meniscus fluid level behind TM
  - air bubbles
  - retraction pockets/TM atelectasis
  - flat tympanogram
  - most reliable finding with pneumatic otoscopy is immobility

Treatment
- expectant: 90% resolve by 3 mo
- document hearing loss with audiogram (see Otolaryngology, Figure 16B, OT10 and Figure 17B, OT11)
- no statistical proof that antihistamines, decongestants, antibiotics clear disease faster
- surgery: myringotomy with tympanostomy (ventilation) tubes ± adenoidectomy (if enlarged or on insertion of second set of tubes after first set falls out)
- tympanostomy (ventilation) tubes to equalize pressure and drain ear

Complications
- hearing loss, speech delay, learning problems in young children
- chronic mastoiditis
- ossicular erosion
- cholesteatoma especially when retraction pockets involve pars flaccida
- retraction of tympanic membrane, atelectasis, ossicular fixation

Gastroenteritis

- see Gastroenterology, G15

HIV Infection

- see Infectious Diseases, ID26

Infectious Paediatric Exanthems

Table 27. Common Infectious Paediatric Exanthems

Disease	Pathogen(s)	Incubation Period	Communicability	Mode of Transmission	Rash	Associated Features	Management	Outcomes and Complications
Erythema Infectiosum (i.e. Fifth Disease/ Slapped Cheek)	Parvovirus B19	4-14 d	Low-risk of transmission once symptomatic	Respiratory secretions or infected blood	Appearance: uniform, erythematous, maculopapular 'lacy' rash Timing: 10-17 d after symptoms (immune response) Distribution: bilateral cheeks ('slapped cheeks') with circumoral sparing; may affect trunk and extremities	Initial 7-10 d of flu-like illness and fever Rash may be warm, non-tender, and pruritic Less common presentations include 'gloves and socks syndrome' or STAR complex (sore throat, arthritis, rash)	Supportive	Rash fades over days to week, but may reappear months later with sunlight, exercise Transient Aplastic crisis (especially if chronic hemolytic anemia)
Gianotti-Crosti Syndrome (i.e. Papular Acrodermatitis)	EBV and Hepatitis B virus (majority)	Variable	None	—	Asymptomatic or pruritic Appearance: symmetric papules Distribution: face, cheeks, extensor surfaces of the extremities, spares trunk	Viral prodrome May have lymphadenopathy and/or hepatosplenomegaly	Supportive Pain control	Resolves in 3-12 wk
Hand, Foot, and Mouth Disease	Coxsackie group A	3-5 d	Likely 1-7 d after symptoms but may be up to months	Direct and indirect contact with infected bodily fluids, fecal-oral	Appearance: vesicles and pustules on an erythematous base Distribution: mouth, buttocks, acral, but may extend up the extremity	Enanthem: vesicles in the POSTERIOR oral cavity (pharynx, tongue)	Supportive	Resolves in 1 wk Mainly dehydration
Herpes Simplex	HSV 1, 2	1-26 d		Direct contact, often through saliva, vertical transmission at birth, or sexual contact	Grouped vesicles on an erythematous base	Enanthem: vesicles/ erosions in the ANTERIOR oral cavity (buccal mucosa, tongue) May present with herpetic whitlow (autoinoculation)	Mainly supportive Consider oral or topical antivirals	Local: secondary skin infections, keratitis, gingivostomatitis CNS: encephalitis Disseminated hepatitis, DIC Eczema herpeticum
Kawasaki Disease	See P98							
Measles	Morbillivirus	8-13 d	4 d before and after rash	Airborne	Appearance: erythematous maculopapular Timing: 3 d after start of symptoms Distribution: starts at hairline and spreads downwards with sparing of palms and soles	Prodrome of cough, coryza, conjunctivitis (3 Cs) Enanthem: Koplik's spots 1-2 d before rash Desquamation Positive serology for measles IgM	Infected: supportive, some evidence for vitamin A. Unimmunized contacts: measles vaccine within 72 h of exposure or IgG within 6 d of exposure Respiratory isolation, report to Public Health Prevention: MMR vaccine	Secondary bacterial infections: AOM, sinusitis, pneumonia Encephalitis Rare: myocarditis, pericarditis, thrombocytopenia, Stevens-Johnson syndrome, GN, subacute sclerosing panencephalitis
Non-Specific Enteroviral Exanthems	Enteroviruses	Variable	Variable	Direct and indirect contact with infected bodily fluids	Polymorphous rash (macules, papules, vesicles, petechiae, urticaria)	Systemic involvement is rare, but possible	Supportive Diagnosis confirmed using viral cultures (nasopharyngeal and rectal swabs)	Self-limiting
Roseola	Human herpes virus (HHV) 6	5-15 d	Droplet transmission	Saliva Perinatal: transplacental infection, germline cell integration	Appearance: blanching, pink, maculopapular Timing: appears once fever subsides Distribution: starts at the neck and trunk and spreads to the face and extremities	High grade fever 3-5 d Common: irritability, anorexia, lymphadenopathy, erythematous TM and pharynx, Nagayama spots (erythematous papules on soft palate and uvula) Less common: cough, coryza, bulging fontanelles	Supportive	Self-limiting CNS: febrile seizures (10-25%), aseptic meningitis Thrombocytopenia

Table 27. Common Infectious Paediatric Exanthems

Disease	Pathogen(s)	Incubation Period	Communicability	Mode of Transmission	Rash	Associated Features	Management	Outcomes and Complications
Rubella	Rubivirus	14-21 d	7 d before and after eruptions	Droplet	Appearance: pink, maculopapular Timing: 1-5 d after start of symptoms Distribution: starts on face and spreads to neck and trunk	Prodrome of low grade fever and occipital/ retroauricular nodes STAR complex (sore throat, arthritis, rash) Positive serology for rubella IgM. Caution to pregnant women with exposure	Supportive Report to Public Health Prevention: MMR vaccine	Excellent prognosis with acquired disease Arthritis may last days to weeks Encephalitis Irreversible defects in congenitally infected patients (i.e. congenital rubella syndrome)
Scarlet Fever	See P65							
Varicella	Varicella zoster virus	10-21 d	1-2 d pre-eruptions and 5 d post-eruption	Direct contact, inhalation of lesion aerosols, aerosolized respiratory secretions	Appearance: groups of skin lesions, polymorphic, from macules to papules to vesicles to crusts Timing: 1-3 d after start of symptoms Distribution: generalized	Significant pruritus Malaise, fever Enanthem: vesicular lesions which may become pustular or ulcerate. Caution to pregnant women	Supportive Avoid salicylates (due to risk of Reye syndrome) Consider antivirals Respiratory and contact isolation, report to Public Health Prevention: varicella vaccine	Skin: bacterial suprainfection, necrotizing fasciitis CNS: acute encephalitis and cerebellar ataxia Systemic: hepatitis, DIC Congenital varicella syndrome if intrapartum infection

Infectious Mononucleosis

Definition
- systemic viral infection caused by EBV with multivisceral involvement; often called "the great imitator"

Epidemiology
- peak incidence between 15-19 yr
- ~50% of children in developed countries have a primary EBV infection by 5 yr, but <10% of children develop clinical infection

Etiology
- EBV: a member of herpesviridae
- transmission is mainly through infected saliva ("kissing disease") and sexual activity (less commonly); incubation period of 1-2 mo

Risk Factors
- infectious contacts, sexually active, multiple sexual partners

History
- prodrome: 2-3 d of malaise, anorexia
- infants and young children: often asymptomatic or mild disease
- older children and adolescents: malaise, fatigue, fever, sore throat, abdominal pain (often LUQ), headache, myalgia

Physical Exam
- classic triad: febrile, generalized non-tender lymphadenopathy, pharyngitis/tonsillitis (exudative)
- ± hepatosplenomegaly
- ± periorbital edema, ± rash (urticarial, maculopapular, or petechial) – more common after inappropriate treatment with β-lactam antibiotics
- any "-itis" (including arthritis, hepatitis, nephritis, myocarditis, meningitis, encephalitis, etc.)

Investigations
- heterophil antibody test (Monospot® test)
  - 85% sensitive in adults and older children, but only 50% sensitive if age <4 yr
  - false positive results with HIV, SLE, lymphoma, rubella, parvovirus
- EBV titres
- CBC and differential, blood smear: reactive lymphocytes, lymphocytosis, Downey cells ± anemia ± thrombocytopenia
- throat culture to rule out streptococcal pharyngitis

Management
- supportive: adequate rest, hydration, saline gargles, and analgesics for sore throat
- splenic enlargement is often not clinically apparent so all patients should avoid contact sports for 6-8 wk
- if airway obstruction secondary to nodal and/or tonsillar enlargement is present (especially younger children), admit for steroid therapy

Prognosis
- most acute symptoms resolve in 1-2 wk, though fatigue may last for months
- short-term complications: splenic rupture, Guillain-Barré syndrome

Infectious Pharyngitis/Tonsillitis

Definition
- inflammation of the pharynx, especially the tonsils if present, causing a sore throat

Etiology
- viral (~80%): adenoviruses, enteroviruses, coxsackie, upper respiratory tract viruses, EBV, CMV, COVID-19
- bacterial (~20%): mainly GAS, *M. pneumoniae* (older children), *N. gonorrhoeae* (sexually active), *C. diphtheriae* (unvaccinated), *Fusobacterium necrophorum* (anaerobe causing Lemierre syndrome)
- fungal: *Candida*

Epidemiology
- season: GAS pharyngitis more common in late winter or early spring; viral all year long
- age: GAS pharyngitis peak incidence at 5-12 yr and uncommon <3 yr; viral pharyngitis affects all ages

Presentation
- GAS: sore throat (may be severe), febrile, malaise, headache, abdominal pain, N/V, absence of other URTI symptoms, pharyngeal/tonsillar erythema and exudates, enlarged (>1 cm) and tender anterior cervical lymph nodes, palatal petechiae, strawberry tongue, scarlatiniform rash
- viral: sore throat (often mild), conjunctivitis, cough, rhinorrhea, hoarseness, diarrhea, flu-like symptoms (fever, malaise, myalgias), absent/mild tonsillar exudates, minor and non-tender adenopathy, viral exanthems

Investigations
- scores are used to predict if throat culture will be positive (e.g. m-CENTOR score)
  - these score systems have not been found to be sensitive or specific enough to diagnose GAS in children and adolescents with sore throat
- suspected diagnosis of GAS pharyngitis should be confirmed with a rapid streptococcal antigen test and a follow-up throat culture if the rapid test is negative

Management
- antibiotics (for GAS/*S. pyogenes*)
  - penicillin V or amoxicillin or erythromycin (if penicillin allergy) x 10 d
  - can prevent rheumatic fever if given within 9 d of symptoms; does NOT alter risk of post-streptococcal GN
- supportive: hydration and acetaminophen for discomfort due to pain and/or fever
- follow-up: if uncomplicated course, no follow-up or post-antibiotic throat cultures needed
- prophylaxis: tonsillectomy may be considered for severe, recurrent streptococcal tonsillitis

Complications
- preventable with antibiotics: AOM, sinusitis, cervical adenitis, mastoiditis, retropharyngeal/peritonsillar abscess, sepsis
- immune-mediated complications: scarlet fever, acute rheumatic fever, post-streptococcal GN, reactive arthritis, paediatric autoimmune neuropsychiatric disorder associated with GAS (i.e. PANDAS)

SCARLET FEVER
- diffuse erythematous eruption
- delayed-type hypersensitivity reaction to pyrogenic exotoxin produced by GAS
- requires prior exposure to *S. pyogenes*
- acute onset of fever, sore throat, strawberry tongue
- 24-48 h after pharyngitis, rash begins in the groin, axillae, neck, antecubital fossa; Pastia's lines may be accentuated in flexural areas
- within 24 h, sandpaper rash becomes generalized with perioral sparing, non-pruritic, non-painful, blanchable
- rash fades after 3-4 d, may be followed by desquamation
- treatment is penicillin, amoxicillin, or erythromycin x 10 d

RHEUMATIC FEVER
- inflammatory disease due to antibody cross-reactivity following GAS infection
- affects ~1 in 10000 children in developed world; much more prevalent in developing nations; peak incidence at 5-15 yr
- clinical diagnosis based on Jones Criteria (revised)
  - requires 2 major OR 1 major and 2 minor PLUS evidence of preceding strep infection (history of scarlet fever, GAS pharyngitis culture, positive rapid Ag detection test, ASOTs)
    - major: carditis and valvulitis, arthritis, CNS involvement (Sydenham chorea), subcutaneous nodules, erythema marginatum
    - minor: arthralgia, fever, ↑ESR or CRP, prolonged PR interval
- treatment: penicillin or erythromycin for acute course x 10 d, prednisone if severe carditis
- secondary prophylaxis with daily penicillin or erythromycin
- complications
  - acute: myocarditis, conduction system aberrations (sinus tachycardia, atrial fibrillation), valvulitis (acute mitral regurgitation), pericarditis
  - chronic: valvular heart disease (mitral and/or aortic insufficiency/stenosis), infectious endocarditis ± thromboembolic phenomenon
  - onset of symptoms usually after 10-20 yr latency from acute carditis of rheumatic fever

POST-STREPTOCOCCAL GLOMERULONEPHRITIS
- most common in children ages 4-8 yr; M>F
- antigen-antibody mediated complement activation with diffuse, proliferative GN
- occurs 1-3 wk following initial GAS infection (skin or throat)
- clinical feature varies from asymptomatic, microscopic and macroscopic hematuria (cola-coloured urine) to all features of nephritic syndrome (see *Nephritic Syndrome*, P83)
- diagnosed upon clinical findings of acute nephritis and recent GAS infection. It can be confirmed with elevated serum antibody titres against streptococcal antigens (ASOT, anti-DNAase B), low serum complement (C3)
- management
  - symptomatic: fluid and sodium restrictions; loop diuretics for HTN and edema
  - in severe cases, may require dialysis if renal function significantly impaired
  - treat with penicillin or erythromycin (if penicillin allergy) if evidence of persistent GAS infection
- 95% of children recover completely within 1-2 wk; 5-10% have persistent hematuria

m-CENTOR Score for Probability of Streptococcal Pharyngitis
For patients presenting with sore throat/pharyngitis and URTI symptoms:
Must be >3 yr
Cough — no cough (+1)
Exudates or Swelling — tonsillar exudates/swelling (+1)
Nodes — anterior Cervical adenopathy (+1)
Temperature — history of fever or temperature >38°C (+1)
Only Young — patients <15 y/o (+1)
Rarely Elder — patients >45 y/o (-1)

Interpretation

m-CENTOR Score	Probability of strep pharyngitis	Recommendation
0	1-2.5%	No further testing or antibiotics
1	5-10%	
2	11-17%	Consider rapid strep testing and/or culture
3	28-35%	
≥4	51-53%	Consider rapid strep testing and/or culture. Empiric antibiotics may be appropriate depending on scenario

Meningitis

Definition
- inflammation of the meninges surrounding the brain and spinal cord

Epidemiology
- peak age: <1 yr; 90% of paediatric cases occur in children age <5 yr

Etiology
- viral: enteroviruses, human parechoviruses, HSV
- bacterial: age-related variation in specific pathogens
- fungal and parasitic meningitis also possible
- most often due to hematogenous spread or direct extension from a contiguous site

Risk Factors
- unvaccinated
- immunocompromised: asplenia, DM, HIV, prematurity
- recent or current infections: AOM, sinusitis, orbital cellulitis
- neuroanatomical: congenital defects, dermal sinus, neurosurgery, cochlear implants, recent head trauma
- exposures: daycare centres, household contact, recent travel

History
- signs and symptoms variable and dependent on age, duration of illness, and host response to infection
- infants: fever, lethargy, irritability, poor feeding, vomiting, diarrhea, respiratory distress, seizures
- children: fever, headache, photophobia, N/V, confusion, back/neck pain/stiffness, lethargy, irritability

Physical Exam
- infants: toxic, hypothermia, bulging anterior fontanelle, respiratory distress, apnea, petechial/purpuric rash, jaundice
- children: toxic, decreased LOC, nuchal rigidity, Kernig's and Brudzinski's signs, focal neurologic findings, petechial/purpuric rash

Investigations
- blood work: CBC, electrolytes, Cr, BUN, glucose, C&S, PTT/INR
- LP required for definitive diagnosis
  - Gram stain, bacterial C&S, WBC count and differential, RBC count, glucose, protein concentration
  - acid-fast stain if suspect TB
  - PCR for specific bacteria if available (helpful if already treated with antibiotics)
  - urinalysis and urine C&S in infants, Gram stain and culture of petechial/purpuric lesions
  - HSV and enterovirus PCR if suspected
  - contraindication: thrombocytopenia and/or DIC
  - decision making around LP should NOT delay empiric antibiotic therapy

Table 28. CSF Findings of Meningitis

Component	Normal Child	Normal Newborn	Bacterial Meningitis	Viral Meningitis	Tuberculosis Meningitis
Lymphocytes ($x10^6$/L)	≤5	0-30	Usually <100	10-1000 (can be normal)	50-1000 (can be normal)
Neutrophils ($x10^6$/L)	0	0	100-10000 (can be normal)	Usually <100	Usually <100
Glucose (CSF:Blood)	≥0.6 (or ≥2.5 mmol/L)	≥0.6 (or ≥2.0 mmol/L)	<0.4 (can be normal)	Usually normal	<0.3 (can be normal)
Protein (g/L)	<0.4	<1.0	>1.0 (can be normal)	0.4-1.0 (can be normal)	1-5 (Can be normal)

Modified from https://www.rch.org.au/clinicalguide/guideline_index/CSF_Interpretation/

Management
- supportive care
  - preservation of adequate cerebral perfusion by maintaining normal BP and managing ICP
  - close monitoring of fluids, electrolytes, glucose, acid-base disturbances, coagulopathies
- bacterial meningitis
  - if suspected or cannot be excluded, commence empiric antibiotic therapy while awaiting cultures or if LP contraindicated or delayed
  - adjuvant dexamethasone BEFORE antibiotic for Hib meningitis; consider for those >6 wk with pneumococcal meningitis
  - isolation with appropriate infection control procedures until 24 h after culture-sensitive antibiotic therapy
  - fluid restrict if any concern for SIADH
  - hearing test
  - report to Public Health; prophylactic antibiotics for close contacts of Hib and N. meningitidis meningitis
- viral meningitis
  - mainly supportive (except for HSV)
  - acyclovir for HSV meningitis
  - report to Public Health
- prophylaxis: appropriate vaccinations significantly decrease incidence of bacterial meningitis (see *Routine Immunization*, P5)

Table 29. Antibiotic Management of Bacterial Meningitis

Age	Main Pathogens	Antibiotics
0-28 d	GBS, *E. coli, Listeria* Other: Gram-negative bacilli	Ampicillin + cefotaxime
28-90 d	Overlap of neonatal pathogens and those seen in older children	Cefotaxime + vancomycin (+ ampicillin if immunocompromised)
>90 d	*S. pneumoniae, N. meningitidis, H. influenzae*	Ceftriaxone ± vancomycin If penicillin allergic: vancomycin + rifampin

Signs of Meningismus

BONK on the head
Brudzinski's sign
Opisthotonos*
Nuchal rigidity
Kernig's sign
*Opisthotonos: rigid spasm of the body, with the back fully arched and the heels and head bent back

Complications
- mortality: neonate 15-20%, children 4-8%; pneumococcus > meningococcus > Hib
- acute: SIADH, subdural effusion/empyema, brain abscess, disseminated infection (osteomyelitis, septic arthritis, abscess), shock/DIC
- chronic: hearing loss, neuromotor/cognitive delay, learning disabilities, neurological deficit, seizure disorder, hydrocephalus

Mumps

Definition
- acute, self-limited viral infection that is most commonly characterized by adenitis and swelling of the parotid glands

Epidemiology
- incidence in Ontario has declined since introduction of two-dose MMR vaccination schedule
- average of 25 reported cases per yr
- majority of reported cases in children age 5-10 yr

Etiology
- mumps virus (RNA virus of the genus Rubulavirus in the Paramyxoviridae family)
- transmission via respiratory droplets, direct contact, fomites
- incubation period: usually 14-16 d (range 12-25 d)
- infectivity period: 7 d pre-parotitis to 5 d post-parotitis
- viral replication in upper respiratory tract, drains to local lymph nodes, then spreads to secondary sites (salivary glands, gonads, pancreas, meninges, kidney, heart, thyroid)

History
- non-specific prodrome of fever, headache, malaise, myalgias (especially neck pain)
- usually followed within 48 h by parotid swelling secondary to parotitis (bilateral, preauricular, ear pushed up and out)
- parotid gland is tender and pain worsened with spicy or sour foods
- one third of infections do not cause clinically apparent salivary gland swelling and may simply present as an URTI

Investigations
- clinical diagnosis, but may be confirmed with IgM positive serology within 4 wk of acute infection
  - may also use PCR or viral cultures from oral secretions, urine, blood, and CSF
  - blood work: CBC (leukopenia with relative lymphocytosis), serum amylase (elevated)

Management
- mainly supportive: analgesics, antipyretics, warm or cold packs to parotid may be soothing
- admit to hospital if serious complications (meningitis, pancreatitis)
- droplet precautions recommended until 5 d after onset of parotid swelling
- prophylaxis: routine vaccination (see *Routine Immunization*, P5)

Complications
- common: aseptic meningitis, orchitis/oophoritis
- less common: encephalitis, pancreatitis, thyroiditis, myocarditis, arthritis, GN, ocular complications, hearing impairment

Pertussis

Definition
- prolonged respiratory illness characterized by paroxysmal coughing and inspiratory "whoop"

Epidemiology
- ~10 million children <1 yr affected worldwide, causes up to 400000 deaths per yr
- greatest incidence among children <1 yr (not fully immunized) and adolescents (waning immunity)

Etiology
- *Bordetella pertussis*: Gram-negative pleomorphic rod
- highly contagious; transmitted via respiratory droplets released during intense coughing
- incubation period: 6-20 d; most contagious during catarrhal phase but may remain contagious for weeks after

History
- prodromal catarrhal stage
  - lasts 1-7 d; URTI symptoms (coryza, mild cough, sneezing) with NO or low-grade fever
- paroxysmal stage
  - lasts 4-6 wk; characterized by paroxysms of cough ("100 day cough"), sometimes followed by inspiratory whoop ("whooping cough")
  - infants <6 mo may present with post-tussive apnea, whoop is often absent
  - onset of attacks precipitated by yawning, sneezing, eating, physical exertion
  - ± post-tussive emesis, may become cyanotic before whoop
- convalescent stage
  - lasts 1-2 wk; characterized by occasional paroxysms of cough, but decreased frequency and severity
  - non-infectious, but cough may last up to 6 mo

Investigations
- NP specimen using aspirate or NP swab
  - gold standard: culture using special media (Regan-Lowe agar)
  - PCR to detect pertussis antigens
- blood work: CBC (lymphocytosis) and serology (antibodies against *B. pertussis*)

Management
- admit if paroxysms of cough are associated with cyanosis and/or apnea and give O_2
- supportive care with attention on nutrition in young infants
- antimicrobial therapy indicated if *B. pertussis* isolated or symptoms present for <21 d
  - use macrolide antibiotics (azithromycin, erythromycin, or clarithromycin)
- droplet isolation until 5 d of treatment and report to Public Health
- prophylaxis
  - macrolide antibiotics for all household contacts
  - prevention with vaccination in infants and children (Pentacel®), and booster in adolescents (Adacel®) (see *Routine Immunization*, P5)

Complications
- pressure-related from paroxysms: subconjunctival hemorrhage, rectal prolapse, hernias, epistaxis
- respiratory: sinusitis, pneumonia, aspiration, atelectasis, pneumomediastinum, pneumothorax, alveolar rupture
- neurological: seizures (~3%), encephalopathy, ICH
- mortality: ~0.3%; highest risk in infants <6 mo

Pneumonia

- see Infectious Diseases, ID7 and *Pneumonia*, P93

Periorbital (Preseptal) and Orbital Cellulitis

- see Ophthalmology, OP9

Cardinal Signs of Orbital Cellulitis
- Ophthalmoplegia/diplopia
- Proptosis
- Decreased visual acuity
- Pain with extraocular eye movement

Sexually Transmitted Infections

- see Family Medicine, FM46 and Gynaecology, GY28

Sinusitis

- see Family Medicine, FM47
- complication of ≤10% of URTIs in children
- clinical diagnosis
- diagnostic imaging is NOT required to confirm diagnosis in children
  - routine CT not recommended, but consider if suspect complications of sinusitis, persistent/recurrent disease, need for surgery
- antibiotic therapy (amoxicillin) for all children (although nearly half resolve spontaneously within 4 wk)
- complications: preseptal/orbital (preseptal/orbital cellulitis, orbital abscess, osteomyelitis, etc.), intracranial (meningitis, abscess, etc.), Pott's Puffy tumour (presents with tender soft tissue erythematous swelling of the forehead; symptoms include headache, photophobia, and fever; managed with IV antibiotics and ENT consult)

Urinary Tract Infection

Definition
- infection of the urinary bladder (cystitis) and/or kidneys (pyelonephritis)

Epidemiology
- overall prevalence in infants and young children presenting with fever is 7%
- <4-6 wk: more common in males
- >1 yr: females have 2-4x higher prevalence

Etiology
- majority (>95%) have a single cause (~70% E. coli)
- Gram-negative bacilli: *E. coli, Klebsiella, Proteus, Enterobacter, Pseudomonas, Citrobacter*
- Gram-positive cocci: *S. saprophyticus, Enterococcus*

Risk Factors
- non-modifiable: female gender, White, previous UTIs, FMHx
- modifiable: urinary tract abnormalities (VUR, neurogenic bladder, obstructive uropathy, posterior urethral valve), dysfunctional voiding, repeated bladder catheterization, uncircumcised males, labial adhesions, sexually active, constipation, toilet training

History
- infants and young child: often just fever or non-specific symptoms (poor feeding, irritability, FTT, jaundice if <28 d, vomiting)
- older child: fever, urinary symptoms (dysuria, urgency, frequency, incontinence, hematuria), abdominal, and/or flank pain

Physical Exam
- infants and young child: toxic vs. non-toxic, febrile, FTT, jaundice; look for external genitalia abnormalities (phimosis, labial adhesions) and lower back signs of occult myelodysplasia (e.g. hair tufts), which may be associated with neurogenic bladder
- older child: febrile, suprapubic and/or costovertebral angle (CVA) tenderness, abdominal mass (enlarged bladder or kidney); may present with short stature, FTT, or HTN secondary to renal scarring from previously unrecognized or recurrent UTIs

Investigations
- sterile urine specimen
  - clean catch, catheterization, suprapubic aspiration or 'Tap and Rub' technique
  - urinalysis (leukocyte esterase, nitrites, erythrocytes, hemoglobin), microscopy (bacteria and leukocytes, erythrocytes), C&S
- diagnosis established if urinalysis suggests infection AND if ≥50000 colony-forming units per mL of a uropathogen cultured

Management
- admit if: age <2 mo, urosepsis, persistent vomiting, inability to tolerate oral medication, moderate-severe dehydration, immunocompromised, complex urologic pathology, inadequate follow-up, failure to respond to outpatient therapy
- supportive care: maintenance of hydration and adequate pain control
- antibiotics
  - base on local antimicrobial susceptibility patterns
  - commence broad empiric therapy until results of urine C&S known, and then tailor as appropriate

Features Suggestive of Pyelonephritis
- High-grade fever
- Flank or high abdominal pain
- CVA tenderness on palpation

Bagged urine specimen not useful for ruling in UTI (high false positive rate >85%), but useful for ruling out UTI (high sensitivity)

Prophylaxis After First Febrile Urinary Tract Infection in Children? A Multicentre, Randomized Controlled, Noninferiority Trial
Pediatrics 2008;122:1064-107
Study: Randomized, controlled, open-label, 2 armed, noninferiority trial.
Patients: 338 patients 2 mo to <7 yr who had a first episode of febrile UTI.
Intervention: No prophylaxis vs. prophylaxis.
Outcome: Recurrence rate of febrile UTI and rate of renal scarring.
Results: No significant difference in recurrence rate or in the rate of renal scarring between the prophylaxis and no prophylaxis group.

  - neonates: IV ampicillin and aminoglycoside
  - infants and older children: oral antibiotics (based on local *E. coli* sensitivity) if outpatient; IV ampicillin and gentamicin if inpatient
  - duration 7-10 d
- imaging
  - renal and bladder U/S for all febrile infants (<2 yr), recurrent febrile UTIs (any age) looking for anatomical abnormalities, hydronephrosis, abscess
  - VCUG not recommended after 1st febrile UTI unless U/S reveals hydronephrosis, obstructive uropathies or other signs suggestive of high-grade VUR
- follow-up:
  - outpatients to return in 24-48 h if no clinical response
  - seek prompt medical evaluation for future febrile illnesses
- prophylaxis: generally not recommended unless higher grades of VUR

Complications
- long-term morbidity: focal renal scarring develops in 8% of patients; long-term significance unknown

Neonatology

Gestational Age and Size

Definitions
- classification by GA
  - preterm: <37 wk (extremely preterm <28 wk, very preterm 28-32 wk, moderate-late preterm 32-37 wk)
  - term: 37-42 wk
  - post-term: >42 wk
- classification by birth weight
  - SGA: 2 SD < mean weight for GA or <10th percentile
  - AGA: within 2 SD of mean weight for GA
  - LGA: 2 SD > mean weight for GA or >90th percentile
- classification of preterm infants by birth weight
  - low birthweight (LBW) <2500 g
  - very low birthweight (VLBW) <1500 g
  - extremely low birthweight (ELBW) <1000 g

Dubowitz/Ballard Scores
GA can be determined after birth using Dubowitz/Ballard scores:
- Assessment at delivery of physical maturity (e.g. plantar creases, lanugo, ear maturation) and neuromuscular maturity (e.g. posture, arm recoil) translates into a score from -10 to +50
- Higher score means greater maturity (increased GA)
- -10 = 20 wk; +50 = 44 wk
- Ideal = 35-40, which corresponds to GA 38-40 wk
- Only accurate ± 2 wk
- May be inaccurate in infants who are preterm, postterm, SGA infants

Table 30. Abnormalities of Gestational Age and Size

Features	Causes	Problems
Pre-Term Infants <37 wk	Spontaneous: cause unknown Maternal disease: HTN, DM, cardiac and renal disorders Fetal conditions: multiple pregnancy, congenital abnormalities, macrosomia, RBC isoimmunization, fetal infection Pregnancy issues: placental insufficiency, placenta previa, uterine malformations, previous preterm birth, infection, placental abruption Behavioural and psychological contributors: smoking, alcohol, drug use, psychosocial stressors Sociodemographic factors: advanced age, low socioeconomic status	RDS, apnea of prematurity, chronic lung disease, bronchopulmonary dysplasia Feeding difficulties, NEC Hypocalcemia, hypoglycemia, hypothermia Anemia, jaundice Retinopathy of prematurity ICH/IVH PDA
Post-Term Infants >42 wk Leathery skin Meconium staining	Most cases unknown Increased in first pregnancies Previous post-term birth Genetic factors	Increased risk of stillbirth or neonatal death Increased birthweight Fetal "postmaturity syndrome": impaired growth due to placental dysfunction Meconium aspiration
SGA Infants <10th percentile Asymmetric (head-sparing): late onset, growth arrest	Extrinsic causes: placental insufficiency, poor nutrition, HTN, multiple pregnancies, drugs, alcohol, smoking, familial factors, fibroids	Perinatal hypoxia Hypoglycemia, hypocalcemia, hypothermia, hyperviscosity (polycythemia), jaundice,
SGA Infants Symmetric: early onset, lower growth	Intrinsic causes: maternal infections (TORCH), congenital abnormalities, syndromal, idiopathic	PDA
LGA Infants >90th percentile	Maternal DM Racial or familial factors Increasing parity Previous LGA infant, high BMI, large pregnancy weight gain Certain syndromes	Birth trauma, perinatal depression (meconium aspiration) RDS, TTN Jaundice, polycythemia Hypoglycemia, hypocalcemia

Routine Neonatal Care

- history taking
  - passage of meconium in 24-48 h, urination/number of wet diapers
  - feeding: breast milk or formula, route (breast or bottle), duration, frequency and volume of feeds
  - issues: jaundice, poor feeding, difficulty breathing, cyanosis, seizures
  - weight: discharge weight (close follow-up if >10% below birth weight), initial weight gain (goal 20-25 g/d), number of days until birth weight regained (should regain by day 10-14 of life)
- erythromycin ointment: applied to both eyes for prophylaxis of ophthalmia neonatorum (*N. gonorrhoeae*); no longer recommended by Canadian Paediatric Society but required by law in some provinces/territories
- vitamin K IM: prophylaxis against VKDB
- newborn screening tests in Ontario
  - in Ontario, newborn screening tests for:
    - metabolic disorders (amino acid disorders, organic acid disorders, fatty acid oxidation defects, biotinidase deficiency, galactosemia)
    - blood disorders (sickle cell disease, other hemoglobinopathies)
    - endocrine disorders (CAH, congenital hypothyroidism)
    - others (CF, severe combined immunodeficiency)
    - congenital hearing loss
- if mother Rh negative: send cord blood for blood group and DAT (also consider sending DAT for O positive mothers)
- if household contact is HBsAg positive: start hepatitis B vaccine series (and if mother is positive, give HBIg within 12 h of birth); the US and some Canadian provinces give Hep B vaccine at birth routinely

Neonatal Resuscitation

- assess Apgar score at 1 and 5 min
- if <7 at 5 min then reassess q5 min, until >7
- do not wait to assign Apgar score before initiating resuscitation

Table 31. Apgar Score

Sign	0	1	2
Heart Rate	Absent	<100/min	>100/min
Respiratory Effort	Absent	Slow, irregular	Good, crying
Irritability	No response	Grimace	Cough/cry
Tone	Limp	Some flexion of extremities	Active motion
Colour	Blue, pale	Body pink, extremities blue (acrocyanosis)	Completely pink

Initial Resuscitation

- anticipation: know maternal history, history of pregnancy, labour, and delivery
- steps to take for all infants
  - pre-delivery team debriefing including assigning roles, checking equipment, and discussing possible complications and management plan
  - warm (radiant heater, warm blankets) and dry the newborn (remove wet blankets)
  - stimulate infant: rub lower back gently or flick soles of feet
  - position airway ("sniffing" position) and clear or suction if necessary
  - assess breathing and HR
  - if apneic or ineffective respiration and HR <100: bag and mask ventilation (PPV) with room air (or 30% if preterm infant). Continue until HR >100 and breathing spontaneously
  - if HR <60: establish airway for effective ventilation and start chest compressions; turn oxygen to 100%
  - if meconium present: a team with advanced resuscitation skills should be present. If the newborn is hypotonic with ineffective respirations, routine intubation for tracheal suction is not suggested unless skilled at intubation. Do initial resuscitation and administer PPV as required

Apgar Score

Appearance (colour)
Pulse (heart rate)
Grimace (irritability)
Activity (tone)
Respiration (respiratory effort)
Or: "How Ready Is This Child?"

Use of 100% Oxygen in Neonatal Resuscitation
Circulation 2015;132(suppl 2):S543-S560
Findings from animal and theoretical studies have suggested potential adverse effects with the administration of 100% oxygen. However, given available data is limited in general and only obtained from newborn samples, the 2015 neonatal resuscitation guidelines have provided the following recommendation: "Since an oxygen saturation of 100% may correspond to a PaO_2 anywhere between ~80 and 500 mmHg, in general it is appropriate to wean the FIO_2 for a saturation of 100%, provided the oxyhemoglobin saturation can be maintained ≥94%." (Class IIb, LOE C).

Corrective Actions for PPV in Neonatal Resuscitation

MR SOPA
Mask readjustment
Reposition airway
Suction mouth and nose
Open mouth
Pressure increase
Alternative airway

Table 32. Interventions Used in Neonatal Resuscitation

Intervention	Schedule	Indications	Comments
Epinephrine (adrenaline)	0.1-0.3 mL/kg/dose of 1:10000 (0.01-0.03 mg/kg) IV 0.5-1 mL/kg/dose of 1:10000 (0.05-0.1 mg/kg) endotracheally can be considered while awaiting IV access (IV preferred) Can be repeated q3-5 min PRN	HR <60 and not rising	Side effects: tachycardia, HTN, cardiac arrhythmias
Fluid Bolus (NS, whole blood, Ringer's lactate)	10 mL/kg May need to be repeated Avoid giving too rapidly as large volume rapid infusions can be associated with IVH	Evidence of hypovolemia	

Targeted Preductal SpO_2 After Birth

1 min	60-65%
2 min	65-70%
3 min	70-75%
4 min	75-80%
5 min	80-85%
10 min	85-95%

Approach to the Depressed Newborn

- a depressed newborn has ineffective respiratory effort and cyanosis
- approximately 10% of newborn babies require assistance with breathing after delivery

Table 33. Etiology of Respiratory Depression in the Newborn

Etiology	Examples
Respiratory Problems	RDS/hyaline membrane disease Pulmonary hypoplasia CNS depression MAS Pneumonia Pneumothorax Pleural effusions Congenital malformations
Anemia (severe)	Erythroblastosis fetalis Secondary hydrops fetalis
Maternal Causes	Drugs/anesthesia (opiates, magnesium sulphate) DM
Congenital Malformations/Birth Injury	Nuchal cord, perinatal depression Bilateral phrenic nerve injury Potter's sequence
Shock	Antepartum hemorrhage
CHD	Transposition of the great arteries with intact ventricular septum
Other	Hypothermia Hypoglycemia Infection

Diagnosis

- vital signs including pre- and post-ductal oxygen saturations and 4 limb BP, hyperoxia test
- detailed maternal and labour history: include prenatal care, illnesses, use of drugs, previous high-risk pregnancies, infections during pregnancy (including GBS status), duration of ruptured membranes, maternal fever or signs of chorioamnionitis during labour/delivery, blood type and Rh status, serologies, amniotic fluid status, GA, meconium, Apgar scores
- clinical findings (observe for signs of respiratory distress such as cyanosis, tachypnea, retractions, grunting, temperature instability, poor tone, abnormal movements, no spontaneous movements)
- laboratory results (CBC, blood gas, blood type and DAT, glucose ± blood culture)
- transillumination of chest to evaluate for pneumothorax if sudden change in respiratory status/worsening distress
- CXR, ECG, echocardiogram, MRI, cerebral function monitoring/EEG

Management

- see *Neonatal Resuscitation*, P71, identify and treat underlying cause

Common Conditions of Neonates

Apnea

Definition

- periodic breathing: normal respiratory pattern seen in newborns in which periods of rapid respiration are alternated with pauses lasting 5-10 s
- apnea: absence of respiratory gas flow for >20 s (or less if associated with bradycardia or desaturation)
- three types of apnea
  - central: no chest wall movement, no signs of obstruction
  - obstructive: chest wall movement continues against obstructed upper airway, no airflow
  - mixed: combination of central and obstructive apnea

Differential Diagnosis
- in term infants, apnea requires full septic workup (CBC and differential, blood and urine cultures ± LP, CXR)
- other causes
  - CNS: seizures, ICH
  - apnea of prematurity (<34 wk): combination of CNS immaturity and obstructive apnea; resolves by 36 wk GA; diagnosis of exclusion
  - hypoxic injury
  - infectious: sepsis, meningitis, NEC
  - GI: GERD, aspiration with feeding
  - metabolic: hypoglycemia, hyponatremia, hypocalcemia, inborn error of metabolism
  - cardiovascular: anemia, hypovolemia, PDA, heart failure
  - medications: morphine

Management
- O_2, ventilatory support, maintain normal blood gases
- tactile stimulation
- correct underlying cause
- medications: methylxanthines (caffeine) stimulate the CNS and diaphragm and are used for apnea of prematurity (not in term infants)
- if apnea of prematurity is diagnosed, infants should receive cardiorespiratory monitoring in a neonatal intensive care unit

Bleeding Disorders in Neonates

Clinical Features
- oozing from the umbilical stump, excessive bleeding from peripheral venipuncture/heel stick sites/IV sites, large caput succedaneum, cephalohematomas (in absence of significant birth trauma), subgaleal hemorrhage and prolonged bleeding following circumcision

Etiology
- 4 major categories
  - increased platelet destruction: maternal ITP or SLE, infection/sepsis, DIC, neonatal alloimmune thrombocytopenia, autoimmune thrombocytopenia
  - decreased platelet production/function: pancytopenia, bone marrow replacement, Fanconi anemia, Trisomy 13 and 18
  - metabolic: congenital thyrotoxicosis, inborn error of metabolism
  - coagulation factor deficiencies (see Hematology, H56): hemophilia A/B, VKDB

NEONATAL ALLOIMMUNE THROMBOCYTOPENIA

Definition
- maternal antibodies directed towards neonatal platelets, causing thrombocytopenia (platelets <150000/microL)

Epidemiology
- 1 in 4000-5000 live births

Pathophysiology
- platelet equivalent of Rh disease of the newborn
- occurs when mother is negative for HPA and fetus is positive
- development of maternal IgG antibodies against HPA antigens on fetal platelets

Clinical Features
- petechiae, purpura, thrombocytopenia in otherwise healthy neonate
- severe disease can lead to intracranial bleeding

Diagnosis
- maternal and paternal platelet typing and identification of platelet alloantibodies

Treatment
- IVIg to mother prenatally starts in second trimester ± steroids ± fetal platelet transfusions
- if transfusion required, use washed maternal platelets or donor HPA negative platelets
- treat neonate with IVIg (less effective than platelet transfusions)

AUTOIMMUNE THROMBOCYTOPENIA

Pathophysiology
- caused by antiplatelet antibodies from maternal ITP or SLE
- passive transfer of antibodies across placenta

Clinical Features
- similar presentation to neonatal alloimmune thrombocytopenia, but thrombocytopenia is usually less severe

Treatment
- steroids to mother for 10-14 d prior to delivery or IVIg to mother before delivery
- treat neonate with IVIg (usually if platelets <60000); otherwise close monitoring for platelet recovery, bleeding
- transfusion of infant with maternal/donor platelets only in severe cases, as antibodies will destroy transfused platelets

VITAMIN K DEFICIENCY BLEEDING
- see *Vitamin K Deficiency*, P52

Bronchopulmonary Dysplasia

Definition
- also known as chronic lung disease
- clinically defined as O_2 requirement for >28 d plus persistent need for oxygen and/or ventilatory support at 36 wk corrected GA
- damage to developing lungs with prolonged intubation/ventilation, high levels O_2, infections

Investigations
- CXR findings may demonstrate decreased lung volumes, areas of atelectasis, signs of inflammation, and hyperinflation

Treatment
- no clearly effective treatments
- gradual wean from ventilator, optimize nutrition
- dexamethasone may help decrease inflammation and encourage weaning, but use of dexamethasone is associated with increased risk of adverse neurodevelopmental outcomes

Prognosis
- chronic respiratory failure may lead to pulmonary HTN, poor growth, and right-sided heart failure
- patients with bronchopulmonary dysplasia may continue to have significant impairment and deterioration in lung function late into adolescence
- some lung abnormalities may persist into adulthood including airway obstruction, airway hyper-reactivity, and emphysema
- associated with increased risk of adverse neurodevelopmental outcomes

Cyanosis

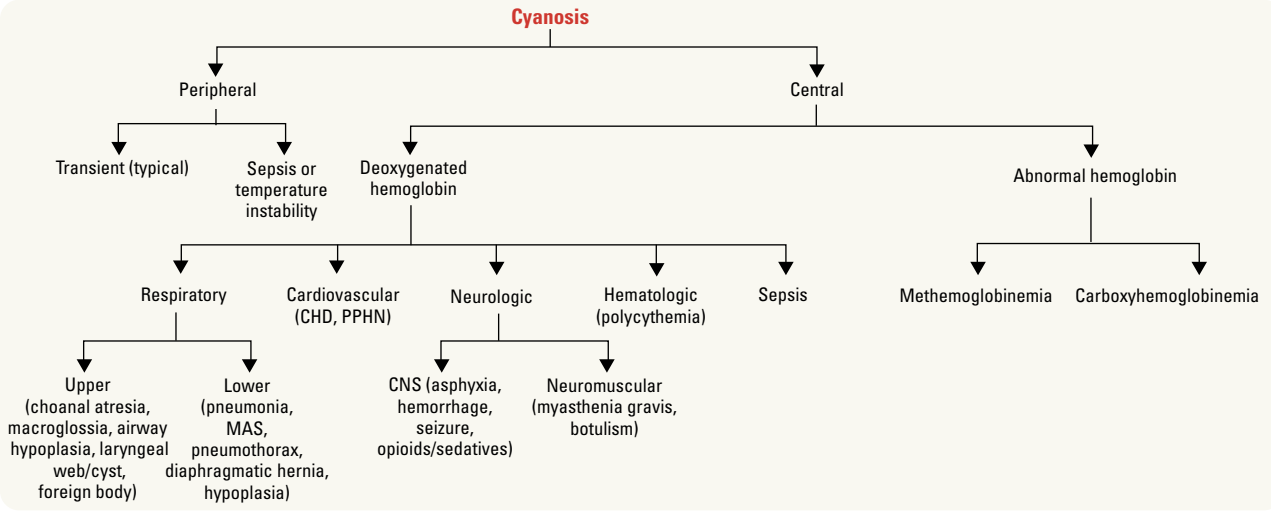

Figure 14. Approach to neonatal cyanosis

Management

- ABGs
  - elevated CO_2 suggests respiratory cause
  - hyperoxia test (to distinguish between cardiac and respiratory causes of cyanosis): get baseline PaO_2 in room air, then PaO_2 on 100% O_2 for 10-15 min
    - PaO_2 <150 mmHg: suggests cyanotic CHD or possible PPHN (see Cardiology and Cardiac Surgery, C19)
    - PaO_2 >150 mmHg: suggests cyanosis likely due to respiratory or non-cardiac cause
- CXR: look for respiratory abnormalities (pneumothorax, respiratory tract malformations, evidence of shunting, pulmonary infiltrates) and cardiac abnormalities (cardiomegaly, abnormalities of the great vessels)

Diaphragmatic Hernia

- see General and Thoracic Surgery, GS73

Definition

- developmental defect of the diaphragm with herniation of abdominal organs into thorax
- associated with pulmonary hypoplasia and PPHN

Clinical Features

- respiratory distress, cyanosis
- scaphoid abdomen and barrel-shaped chest
- affected side dull to percussion and breath sounds absent, may hear bowel sounds instead
- heart sounds shifted to contralateral side, if left sided diaphragmatic hernia
- asymmetric chest movements, trachea deviated away from affected side
- may present outside of neonatal period
- often associated with other anomalies (cardiovascular, neural tube defects, chromosomal abnormalities)
- CXR for diagnosis
- CXR: bowel loops in thorax (usually left side), displaced mediastinum

Treatment

- immediate intubation required at birth: DO NOT bag mask ventilate because air will enter stomach and further compress lungs
- place large bore orogastric tube to decompress bowel
- initial stabilization and management of pulmonary hypoplasia and PPHN if present, hemodynamic support and surgery when stable

Hypoglycemia

Definition
- glucose <2.6 mmol/L within 72 h of birth

Etiology
- decreased carbohydrate stores: premature, SGA, RDS, maternal HTN
- endocrine: hormonal deficiencies (GH, cortisol, epinephrine), insulin excess (infant of diabetic mother, LGA, Beckwith-Wiedemann syndrome/islet cell hyperplasia), hypothalamic-pituitary-adrenal axis suppression (panhypopituitarism)
- inborn errors of metabolism: fatty acid oxidation defects, galactosemia
- miscellaneous: sepsis, hypothermia, polycythemia, perinatal stress (eg. asphyxia)

Clinical Findings
- signs often non-specific and subtle: lethargy, poor feeding, irritability, tremors, apnea, cyanosis, seizures

Management
- identify and monitor infants at risk (pre-feed blood glucose checks) until blood glucose stable and for at least 12 h (for infant of diabetic mother or LGA) or 36 h (if preterm or SGA)
- in a well at-risk infant, begin oral feeds as soon as possible after birth and ensure regular feeds, check glucose at 2 h of age
- if significant and/or symptomatic hypoglycemia, provide glucose IV (D10W) and titrate according to blood sugar levels
- if persistent hypoglycemia (>48 h of life), prolonged glucose IV, severe symptomatic hypoglycemia (coma, lethargy, seizure), or no predisposing cause, send "critical blood work" during an episode of hypoglycemia: ABG, ammonia, β-hydroxybutyrate, cortisol, free fatty acids, GH, insulin, lactate, urine dipstick for ketones

Neonatal Hyperbilirubinemia

Definition
- total serum bilirubin >95th percentile (high-risk zone) on Bhutani nomogram in infants >35 wk GA

Clinical Features
- jaundice typically visible at serum bilirubin levels of 85-120 μmol/L
- visual assessment is misleading, confirm jaundice with blood test

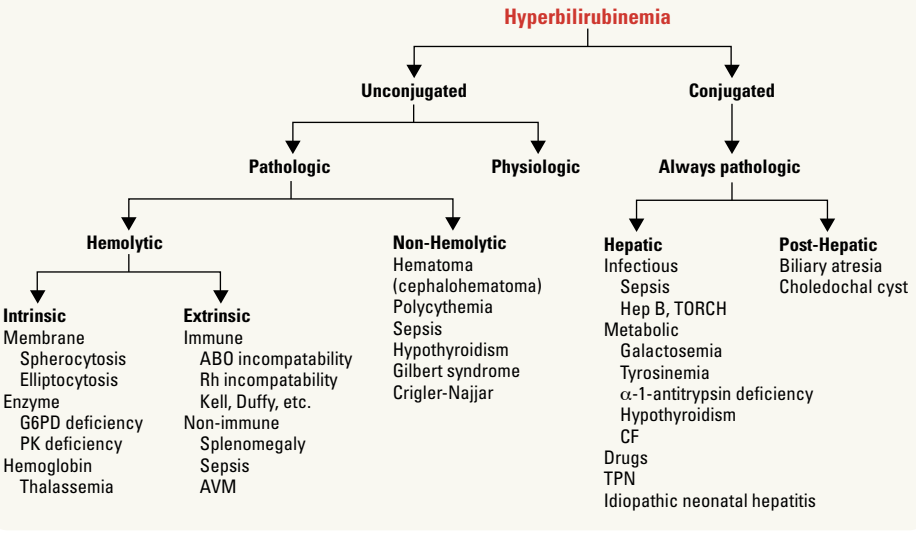

Figure 15. Approach to neonatal hyperbilirubinemia

Jaundice is very common – 60% of term newborns develop visible jaundice

Jaundice in the first 24 h of life and conjugated hyperbilirubinemia are always pathological

Jaundice must be investigated if:
- It occurs within 24 h of birth
- Conjugated hyperbilirubinemia is present
- Unconjugated bilirubin rises rapidly or is excessive for patient's age and weight
- Persistent jaundice lasts beyond 1-2 wk of age

PHYSIOLOGIC JAUNDICE

Epidemiology
- term infants: onset 3-4 d of life, resolution by 10 d of life
- premature infants: higher peak and longer duration

Pathophysiology
- increased hematocrit and decreased RBC lifespan
- immature glucuronyl transferase enzyme system (slow conjugation of bilirubin)
- increased enterohepatic circulation

Breastfeeding Jaundice
- common: due to a lack of milk production ➔ dehydration ➔ exaggerated physiologic jaundice

Breast Milk Jaundice
- 1 in 200 breastfed infants
- glucuronyl transferase inhibitor found in breast milk
- onset 7 d of life, peak at 2-3 wk of life, usually resolved by 6 wk

Table 34. Risk Factors for Jaundice

Maternal Factors	Perinatal Factors	Neonatal Factors
Ethnic group (e.g. Asian, Indigenous)	Birth trauma (cephalohematoma, ecchymoses)	Difficulty establishing breastfeeding
Complications during pregnancy (infant of diabetic mother, Rh or ABO incompatibility)	Prematurity	Infection (sepsis, hepatitis)
Breastfeeding		Genetic factors
FMHx/previous child required phototherapy		Polycythemia
		Drugs
		TPN

Table 35. Causes of Neonatal Jaundice by Age

<24 h	24-72 h	72-96 h	Prolonged (>1 wk)
ALWAYS PATHOLOGIC	Physiologic, polycythemia	Physiologic ± breastfeeding	Breast milk jaundice
Hemolytic	Dehydration (breastfeeding jaundice)	Sepsis	Prolonged physiologic jaundice in preterm
Rh or ABO incompatibility	Hemolysis		Hypothyroidism
Sepsis	G6PD deficiency		Neonatal hepatitis
Congenital infection (TORCH)	Pyruvate kinase deficiency		Conjugation dysfunction
Severe bruising/hemorrhage	Spherocytosis		e.g. Gilbert syndrome,
	Bruising, hemorrhage,		Crigler-Najjar syndrome
	hematoma		Inborn errors of metabolism
	Sepsis/congenital infection		e.g. galactosemia
			Biliary tract obstruction
			e.g. biliary atresia

PATHOLOGIC JAUNDICE
- all cases of conjugated hyperbilirubinemia; some cases of unconjugated hyperbilirubinemia are pathologic

Investigations
- unconjugated hyperbilirubinemia
  - hemolytic workup: CBC, reticulocyte count, blood group (mother and infant), peripheral blood smear, Coombs test (DAT)
  - if baby is unwell or has fever: septic workup (CBC and differential, blood and urine cultures ± LP, CXR)
  - other: G6PD screen (especially in males), TSH
- conjugated hyperbilirubinemia must be investigated without delay
  - consider liver enzymes (AST, ALT), coagulation studies (PT, PTT), serum albumin, ammonia, TSH, TORCH screen, septic workup, galactosemia screen (erythrocyte galactose-1-phosphate uridyltransferase levels), metabolic screen, abdominal U/S, HIDA scan, sweat chloride
- predicting occurrence of severe hyperbilirubinemia
  - measure either total serum bilirubin (TSB) or transcutaneous bilirubin (TcB) concentration in all infants between 24 h and 72 h of life and plot on appropriate hyperbilirubinemia treatment graph. If infant does not require immediate treatment, results should be plotted on predictive nomogram to determine the risk of progression to severe hyperbilirubinemia and need for repeat measurement (refer to: http://www.cps.ca/documents/position/hyperbilirubinemia-newborn)

TREATMENT OF UNCONJUGATED HYPERBILIRUBINEMIA

- to prevent kernicterus
- breastfeeding does not usually need to be discontinued, ensure adequate feeds and hydration
- lactation consultant support, mother to pump after feeds
- treat underlying causes (e.g. sepsis)
- phototherapy (blue-green wavelength, not UV light); standard intensive or multiple intensive protocol depending on severity of hyperbilirubinemia
  - insoluble unconjugated bilirubin is converted to excretable form via photoisomerization
  - serum bilirubin should be monitored during and immediately after therapy (risk of rebound because photoisomerization is reversible when phototherapy is discontinued)
  - contraindicated in conjugated hyperbilirubinemia: results in "bronzed" baby
  - side effects: skin rash, diarrhea, eye damage (eye shield used routinely for prevention), dehydration
  - use published guidelines and nomogram (see Figure 16) to determine appropriateness of phototherapy by stratifying infant risk and assessing if total serum bilirubin level is above cutoff for respective gestational age
- exchange transfusion
  - indications: high bilirubin levels as per published graphs based on age, weeks gestation
  - most commonly performed for hemolytic disease and G6PD deficiency
  - use of IVIg in case of severe hyperbilirubinemia (DAT+) becoming evidence-based practice

"Bronzed" Baby in Infants with Conjugated Hyperbilirubinemia Phototherapy results in the production and accumulation of a toxic metabolite which also imparts a bronze hue on the baby's skin

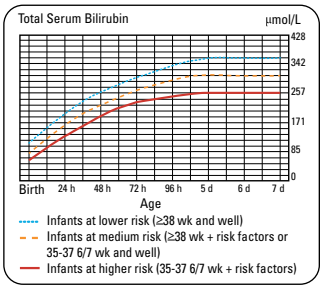

Figure 16. Gold standard in deciding when to initiate phototherapy for unconjugated hyperbilirubinemia
Licence number: 4601410094382

KERNICTERUS

Etiology

- unconjugated bilirubin concentrations exceed albumin binding capacity and bilirubin is deposited in the brain resulting in tissue necrosis and permanent damage (typically basal ganglia or brainstem)
- incidence increases as serum bilirubin levels increase above 340 µmol/L
- can occur at lower levels in presence of sepsis, meningitis, hemolysis, hypoxia, acidosis, hypothermia, hypoglycemia, and prematurity

Clinical Features

- up to 15% of infants have no obvious neurologic symptoms
- early stage: lethargy, hypotonia, poor feeding, emesis (acute bilirubin encephalopathy)
- mid stage: hypertonia, high pitched cry, opisthotonic posturing (back arching), bulging fontanelle, seizures, pulmonary hemorrhage
- late stage (during first year and beyond): hypotonia, delayed motor skills, extrapyramidal abnormalities (choreoathetoid CP), gaze palsy, mitral regurgitation, sensorineural hearing loss

Prevention

- exchange transfusion, IVIg if indicated

BILIARY ATRESIA

Definition

- atresia of the extrahepatic bile ducts which leads to cholestasis and increased conjugated bilirubin after the first wk of life
- progressive obliterative cholangiopathy

Epidemiology

- incidence: 1 in 10000-15000 live births
- associated anomalies in 10-35% of cases: situs inversus, congenital heart defects, polysplenia

Clinical Features

- dark urine, pale stool, jaundice (persisting for >2 wk), abdominal distension, hepatomegaly

Diagnosis

- conjugated hyperbilirubinemia, abdominal U/S, operative cholangiogram
- HIDA scan (may be bypassed in favour of biopsy if timing of diagnosis is critical)
- liver biopsy

Treatment

- surgical drainage procedure
- hepatoportoenterostomy (Kasai procedure; most successful if age <8 wk)
- two-thirds will eventually require liver transplantation
- vitamins A, D, E, and K; diet should be enriched with medium-chain triglycerides to ensure adequate fat ingestion

Necrotizing Enterocolitis

Definition
- intestinal inflammation associated with focal or diffuse ulceration and necrosis
- primarily affecting terminal ileum and colon

Epidemiology
- affects 1-5% of preterm newborns admitted to NICU

Pathophysiology
- postulated mechanism of bowel ischemia: mucosal damage and enteral feeding → bacterial growth → bowel necrosis/gangrene/perforation

Risk Factors
- prematurity (immature defenses)
- asphyxia, shock (poor bowel perfusion)
- hyperosmolar feeds
- enteral feeding with formula (breast milk can be protective)
- sepsis

Clinical Features
- usually presents at age 2-3 wk
- distended abdomen, diminished bowel sounds, feeding intolerance
- increased amount of gastric aspirate/vomitus with bile staining
- frank or occult blood in stool
- signs of bowel perforation (sepsis, shock, peritonitis, DIC)

Investigations
- AXR: pneumatosis intestinalis (intramural air is a hallmark of NEC), free air, fixed loops, ileus, thickened bowel wall, portal venous gas
- CBC, ABG, lactate, blood culture, electrolytes
- high or low WBC, low platelets, hyponatremia, acidosis, hypoxia, hypercapnia

Treatment
- NPO (7-10 d), vigorous IV fluid resuscitation, decompression with NG tube, supportive therapy
- TPN
- antibiotics (usually ampicillin, gentamicin ± metronidazole if risk of perforation x 7-10 d)
- serial AXRs detect early perforation (40% mortality in perforated NEC)
- peritoneal drain/surgery if perforation
- surgical resection of necrotic bowel and surgery for complications (e.g. perforation, strictures)

Influence of Enteral Nutrition on Occurrences of Necrotizing Enterocolitis in Very-Low-Birth-Weight Infants
J Pediatr Gastroenterol Nutr 2015;61(4):445-450
Study: Case-control study of very-low-birth-weight (VLBW) infants and occurrences of NEC within 30 d of life.
Population: 1028 VLBW infants in neonatal intensive care unit Jan 2003-May 2008.
Primary Outcome: NEC defined using stage ≥2 of modified Bell criteria.
Results: 55 infants developed NEC within 30 d of life (5.4%). Those with NEC had higher odds of having been fed breast milk <7 d (OR: 4.02), not having achieved full enteral feeding during the first mo (OR: 3.50), and having had parenteral feeding (OR: 2.70).
Conclusions: Occurrence of NEC can be reduced with breast milk feeding beyond 7 d and early full enteral feeding.

Persistent Pulmonary Hypertension of the Newborn

Definition
- persistence of fetal circulation as a result of persistent elevation of pulmonary vascular resistance
- classified as primary (absence of risk factors) or secondary

Epidemiology
- incidence 1.9 in 1000 live births

Clinical Features
- usually presents within 12 h of birth with severe hypoxemia/cyanosis; some may have only mild respiratory distress

Pathophysiology
- elevated pulmonary pressures cause R → L shunt through PDA, foramen ovale → decreased pulmonary blood flow and hypoxemia → further pulmonary vasoconstriction

Risk Factors
- secondary PPHN: asphyxia, meconium aspiration syndrome, RDS, sepsis, pneumonia, structural abnormalities (e.g. diaphragmatic hernia, pulmonary hypoplasia)
- more common in term or post-term infants

Investigations
- measure pre- and post-ductal oxygen levels
- hyperoxia test to exclude CHD
- ECG (RV strain)
- echo reveals increased pulmonary arterial pressure and a R → L shunt across PDA and patent foramen ovale; also used to rule out other cardiac defects

Treatment
- maintain good oxygenation (SaO_2 >95%) in at-risk infants
- O_2 given early and tapered slowly, minimize stress and metabolic demands, maintain normal blood gases, circulatory support
- mechanical ventilation, high frequency oscillation in a sedated muscle-relaxed infant
- nitric oxide, surfactant
- extracorporeal membrane oxygenation used in some centres when other therapy fails

Respiratory Distress in the Newborn

Clinical Features
- tachypnea: RR >60/min; tachycardia: HR >160/min
- grunting, subcostal/intercostal indrawing, nasal flaring
- duskiness, central cyanosis
- decreased air entry, crackles on auscultation

Differential Diagnosis of Respiratory Distress
- see Table 33 under *Neonatal Resuscitation*, P72

Investigations
- labs: CBC, blood gas, glucose, blood culture
- imaging: CXR
- if indicated: ECG, echo, LP (CSF cell count, culture, and chemistry)

Table 36. Distinguishing Features of RDS, TTN, MAS

	RDS	TTN	MAS
Etiology	Surfactant deficiency → poor lung compliance due to high alveolar surface tension → atelectasis → ↓ surface area for gas exchange → hypoxia + acidosis → respiratory distress "Hyaline membrane disease"	Delayed resorption of fetal lung fluid → accumulation of fluid in peribronchial lymphatics and vascular spaces → tachypnea "Wet lung syndrome"	Meconium is sterile but causes airway obstruction, chemical inflammation, and surfactant inactivation leading to chemical pneumonitis
Gestational Age	Preterm	Usually term and late preterm	Term and post-term
Risk Factors	Maternal DM Preterm delivery Male sex LBW Acidosis, sepsis Hypothermia Second born twin	Maternal DM Maternal asthma Male sex Macrosomia (>4500 g) Elective Cesarean section or short labour Late preterm delivery	Meconium-stained amniotic fluid Post-term delivery
Clinical Features	Respiratory distress within first few hours of life, worsens over next 24-72 h Hypoxia Cyanosis	Tachypnea within the first few hours of life ± retractions, grunting, nasal flaring Often NO hypoxia or cyanosis	Respiratory distress within hours of birth Small airway obstruction, chemical pneumonitis tachypnea, barrel chest with audible crackles Hypoxia
CXR Findings	Homogenous infiltrates Air bronchograms Decreased lung volumes May resemble pneumonia (GBS) If severe, "white-out" with no differentiation of cardiac border	Perihilar infiltrates "Wet silhouette;" fluid in fissures	Hyperinflation Patchy atelectasis Patchy and coarse infiltrates 10-20% have pneumothorax
Prevention	Prenatal corticosteroids (e.g. Celestone® 12 mg q24 h x 2 doses) if risk of preterm delivery <34 wk Monitor lecithin:sphingomyelin (L/S) ratio with amniocentesis, L/S >2:1 indicates lung maturity	Where possible, avoidance of elective Cesarean delivery, particularly before 38 wk GA	If infant is depressed at birth, intubate and suction below vocal cords Avoidance of factors associated with in utero passage of meconium (e.g. post-term delivery)
Treatment	Resuscitation Oxygen Ventilation Surfactant (decreases alveolar surface tension, improves lung compliance, and maintains functional residual capacity)	Supportive Oxygen if hypoxic Ventilator support (e.g. CPAP) IV fluids and NG tube feeds if too tachypneic to feed orally	Resuscitation Oxygen Ventilatory support Surfactant Inhaled nitric oxide Extracorporeal membrane oxygenation for PPHN
Complications	In severe prematurity and/or prolonged ventilation, increased risk of bronchopulmonary dysplasia	Hypoxemia Hypercapnia Acidosis PPHN	Hypoxemia Hypercapnia Acidosis PPHN Pneumothorax Pneumomediastinum Chemical pneumonitis Secondary surfactant inhibition Respiratory failure
Prognosis	Dependent on GA at birth and severity of underlying lung disease; long-term risks of chronic lung disease	Recovery usually expected in 24-72 h	Dependent on severity, mortality up to 20%

PNEUMONIA

- see *Respirology*, P93
- consider in infants with prolonged (≥18 h) or premature rupture of membranes, maternal fever or other signs and symptoms of chorioamnionitis, or if mother is GBS positive
- suspect if infant exhibits respiratory distress, temperature instability, or WBC is low (<5 x 10^9/L), elevated (>30 x 10^9/L), or left-shifted
- symptoms may be non-specific (e.g. lethargy, apnea, tachycardia, poor perfusion, poor feeding)
- investigations: CXR (hazy lung and/or distinct infiltrates, may be difficult to differentiate from RDS), blood and CSF cultures
- neonates with pneumonia should be admitted to the NICU and given empiric antibiotics for management

Retinopathy of Prematurity

- see Ophthalmology, OP40

Sepsis in the Neonate

Table 37. Sepsis Considerations in the Neonate

Early Onset (<72 h)	Late Onset (72 h - 28 d)
Vertical transmission, 95% present within 24 h after birth Risk factors: Maternal infection: UTI, GBS positive, previous child with GBS, sepsis, or meningitis Maternal fever/leukocytosis/chorioamnionitis Prolonged rupture of membranes (>18 h) Preterm labour Pathogens: GBS, *E. coli, Listeria* are most common Pneumonia more common with early-onset sepsis	Acquired after birth Most common in preterm infants in NICU (most commonly due to coagulase-negative *Staphylococcus*) Other pathogens implicated include GBS, anaerobes, *E. coli, Klebsiella*

Chronic Perinatal Infections

CHEAP TORCHES
Chicken pox/shingles
Hepatitis B/C/D/E
Enteroviruses
AIDS (HIV)
Parvovirus B19 (erythema infectiosum)
Toxoplasmosis
Other
Rubella virus
Cytomegalovirus/Coxsackievirus
HSV
Every STI
Syphilis

Clinical Features

- no reliable absolute indicator of occult bacteremia in infants <3 mo, most specific result has been WBC <5x10^9/L
- temperature instability (hypo/hyperthermia)
- respiratory distress, cyanosis, apnea
- tachycardia/bradycardia
- lethargy, irritability
- poor feeding, vomiting, abdominal distension, diarrhea
- hypotonia, seizures, lethargy
- jaundice, hepatomegaly, petechiae, purpura

Investigations

- suspicion of neonatal sepsis requires "full septic workup"
  - CBC, blood and urine cultures, LP (CSF analysis: cell count, glucose, protein, culture, and PCR for viruses) ± CXR
  - LP must be conducted if blood culture is positive due to increased risk of meningitis

Management

- supportive care
- IV antibiotics: typically ampicillin + cefotaxime or ampicillin + gentamicin chosen as first-line empiric therapy
- choice of antibiotic and duration of treatment dependent on symptoms, culture results, maternal GBS status, and local resistance patterns
- if meningitis suspected, consider IV ampicillin + cefotaxime ± vancomycin at meningitic doses
- addition of IV acyclovir if HSV infection suspected

Skin Conditions of the Neonate

Table 38. Common Neonatal Skin Conditions

Neonatal Skin Condition	Description
Vasomotor Response (Cutis Marmorata, Acrocyanosis)	Transient mottling when exposed to cold; usually normal, particularly if premature
Vernix Caseosa	Soft, creamy, white layer covering baby at birth
Congenital Dermal Melanocytosis	Slate grey patches over lower back, buttocks, and lower limbs (may look like bruises); prevalence varies with ethnicity (Asian > Black > Hispanic > White); typically fades within first 2 yr of life
Capillary Hemangioma	Raised red lesion, which increases in size after birth and involutes; 50% resolved by 5 yr, 90% by 9 yr
Erythema Toxicum Neonatorum	Yellow-white papules/pustules surrounded by erythema, eosinophils within the lesions; common rash, resolves in 5-7 d
Milia	1-2 mm firm white pearly papules on nasal bridge, cheeks, and palate; self-resolves within first few weeks of life
Transient Pustular Melanosis	Hyperpigmented macular base with pustules, seen more commonly in Black infants; may be present at birth; no treatment needed
Nevus Simplex (Salmon Patch)	Transient macular vascular malformation of the eyelids and/or neck ("Angel Kiss" or "Stork Bite"); most lesions disappear by 1 yr
Neonatal Acne	Inflammatory papules and pustules mainly on face; self-resolving usually within 4 mo

Nephrology

Common Paediatric Renal Diseases

Table 39. Common Manifestations of Renal Disease

Age	Symptoms	Common Causes
Neonate	Flank Mass	Hydronephrosis, polycystic disease (autosomal dominant or recessive subtypes), tumour
	Hematuria	Renal vein thrombosis, asphyxia, malformation, trauma
	Anuria/Oliguria	Bilateral renal agenesis, obstruction, asphyxia
Child and Adolescent	Cola/Red-Coloured Urine	Acute GN (e.g. post-streptococcal, HSP, IgA nephropathy, etc.), hemoglobinuria (hemolysis), myoglobinuria (rhabdomyolysis)
	Gross Hematuria	Urologic disease (e.g. nephrolithiasis, trauma, etc.), UTI, acute GN
	Edema	Nephrotic syndrome, nephritis, acute/chronic renal failure, consider cardiac or liver disease
	Hypertension	GN, renal failure, dysplasia (consider coarctation, drugs, endocrine causes)
	Polyuria	DM, central and nephrogenic DI, renal Fanconi's syndrome (genetic/metabolic/acquired causes), hypercalcemia, polyuric renal failure (renal dysplasia)
	Proteinuria	Orthostatic, nephrotic syndrome (MCD, etc.), GN
	Oliguria	Dehydration, ATN, interstitial nephritis, acute or chronic kidney disease (i.e. renal failure)
	Urgency	UTI, vulvovaginitis

Hemolytic Uremic Syndrome

Definition

- simultaneous occurrence of the triad of:
  1. non-immune microangiopathic hemolytic anemia
  2. thrombocytopenia
  3. acute renal injury

Epidemiology

- annual incidence of 1-2 in 100000 in Canada
- most common cause of acute renal failure in children

Etiology

- STEC-HUS: 90% of paediatric HUS; caused by Shiga toxin-producing *E. coli* (usually O157:H7)
- atypical HUS: 10% of paediatric HUS; caused by hereditary mutations, non-Shiga toxin infections (e.g. *S. pneumoniae*, HIV), and drugs

Pathophysiology
- toxin binds, invades, and destroys colonic epithelial cells, causing bloody diarrhea
- toxin enters the systemic circulation, attaches to, and injures endothelial cells (especially in the kidney), causing a release of endothelial products (e.g. von Willebrand factor, platelet aggregating factor)
- platelet/fibrin thrombi form in multiple organ systems (e.g. kidney, pancreas, brain) resulting in thrombocytopenia
- RBCs are forced through occluded vessels, resulting in fragmented RBCs (schistocytes) that are removed by the reticuloendothelial system (hemolytic anemia)

Clinical Features
- initial presentation of abdominal pain and diarrhea, followed by bloody diarrhea; within 5-7 d begins to show signs of anemia, thrombocytopenia, and renal insufficiency
- pallor, jaundice (hemolysis), edema, petechiae, HTN, decreased urine output

Investigations
- CBC (anemia, thrombocytopenia), blood smear (schistocytes), electrolytes (due to fluid loss), renal function, urinalysis (microscopic hematuria), stool cultures, and verotoxin/shigella toxin assay

Management
- mainly supportive: nutrition, hydration, ventilation (if necessary), blood products
- dialysis if symptomatic uremia, refractory electrolyte abnormality (e.g. hyperkalemia), or severe fluid overload
- STEC-HUS: avoid antibiotics, NSAIDs, and antidiarrheal agents; no treatments associated with improved outcomes
- atypical HUS: plasma exchange or eculizumab

Prognosis
- STEC-HUS: <5% mortality rate, 30% develop long-term renal damage (e.g. HTN, proteinuria, decreased GFR)
- atypical HUS: worse prognosis compared to STEC-HUS, 50% of cases result in death or dialysis-dependent renal disease

Nephritic Syndrome

Nephritic Syndrome

PHAROH
Proteinuria (<50 mg/kg/d)
Hematuria
Azotemia
RBC casts
Oliguria
HTN

Definition
- acute or chronic syndrome affecting the kidney, characterized by glomerular injury and inflammation
- defined by hematuria (>5 RBCs per high-powered microscope field), presence of dysmorphic RBCs, and RBC casts on urinalysis
- often accompanied by at least one of: proteinuria (<50 mg/kg/d), edema, HTN, azotemia, and oliguria

Epidemiology
- highest incidence in children ages 5-15 yr

Etiology
- humoral immune response to a variety of etiologic agents ➔ immunoglobulin deposition ➔ complement activation, leukocyte recruitment, release of growth factors/cytokines ➔ glomerular inflammation and injury ➔ porous podocytes ➔ hematuria + RBC casts ± proteinuria
- HTN secondary to fluid retention and increased renin secretion by ischemic kidneys

Table 40. Major Causes of Nephritic Syndrome

	Decreased C3	Normal C3
Primary (idiopathic)	Post-infectious GN (streptococcal infection is the most common) Membranoproliferative Type I (50-80%) Type II (>80%)	IgA nephropathy Idiopathic rapidly progressive GN Anti-GBM disease
Secondary (systemic disease)	SLE Bacterial endocarditis Abscess or shunt nephritis Cryoglobulinemia	HSP (very common) Polyarteritis nodosa Granulomatosis with polyangiitis Goodpasture's syndrom

Clinical Features
- often asymptomatic; some overlap in clinical findings for nephritic and nephrotic syndrome
- gross hematuria, mild-moderate edema, oliguria, HTN
- signs and symptoms suggestive of underlying systemic causes (e.g. fever, arthralgias, rash, dyspnea, pulmonary hemorrhage)

Investigations
- urine
  - dipstick (hematuria, 0 to 2+ proteinuria) and microscopy (>5 RBCs per high-powered microscope field, acanthocytes, RBC casts)
  - first morning urine protein/creatinine ratio (<200 mg/mmol)
- blood work
  - CBC, electrolytes, Cr, BUN, albumin
  - impaired renal function (↑ Cr and BUN) resulting in ↑ pH and electrolyte abnormalities (hyperkalemia, hyperphosphatemia, hypocalcemia)
  - mild anemia on CBC (secondary to hematuria)
  - hypoalbuminemia (secondary to proteinuria)
  - appropriate investigations to determine etiology: C3/C4 levels, serologic testing for recent streptococcal infection (ASOT, anti-hyaluronidase, anti-streptokinase, anti-NAD, anti-DNAse B), ANA, anti-DNA antibodies, ANCA, serum IgA levels, anti-GBM antibodies
- renal biopsy should be considered only in the presence of acute renal failure, no evidence of streptococcal infection, normal C3/C4

Management
- treat underlying cause
- symptomatic
  - renal insufficiency: supportive (dialysis if necessary), proper hydration
  - HTN: salt and fluid restriction (but not at expense of renal function), ACEI or ARBs for chronic persistent HTN (not acute cases because ACEI or ARBs may decrease GFR further)
  - edema: salt and fluid restriction, possibly diuretics (avoid if significant intravascular depletion)
- corticosteroids if indicated: IgA nephropathy, lupus nephritis, etc.
- post-streptococcal GN should be monitored for complications long term (annual BP, urinalysis)

Prognosis
- dependent on underlying etiology
- complications include HTN, heart failure, pulmonary edema, chronic kidney injury (requiring renal transplant)

Nephrotic Syndrome

Definition
- clinical syndrome affecting the kidney, characterized by significant proteinuria, peripheral edema, hypoalbuminemia, and hyperlipidemia

Nephrotic Syndrome - HELP
Hypoalbuminemia (<20 g/L)
Edema
Lipids elevated
Proteinuria (>50 mg/kg/d)

Epidemiology
- highest incidence in children 2-6 yr, M>F

Etiology
- primary (idiopathic): nephrotic syndrome in the absence of systemic disease (most common cause in paediatrics)
  - glomerular inflammation ABSENT on renal biopsy: MCD (85%), focal segmental glomerulosclerosis
  - glomerular inflammation PRESENT on renal biopsy: membranoproliferative GN, IgA nephropathy
- secondary: nephrotic syndrome associated with systemic disease or due to another process causing glomerular injury (<10% in paediatrics)
  - autoimmune: SLE, DM, rheumatoid arthritis
  - genetic: sickle cell disease, Alport syndrome
  - infections: hepatitis B/C, post-streptococcal, infective endocarditis, HUS, HIV
  - malignancies: leukemia, lymphoma
  - medications: captopril, penicillamine, NSAIDs, antiepileptics
  - vasculitides: HSP, granulomatosis with polyangiitis
- congenital: congenital nephropathy of the Finnish type, Denys-Drash syndrome, etc.

Clinical Features

- edema
  - often first sign; detectable when fluid retention exceeds 3-5% of body weight
  - starts periorbital and often pretibial → edematous areas are white, soft, and pitting
  - gravity dependent: periorbital edema ↓ and pretibial edema ↑ over the day
  - anasarca may develop (i.e. marked periorbital and peripheral edema, ascites, pleural effusions, scrotal/labial edema)
- non-specific symptoms such as irritability, malaise, fatigue, anorexia, or diarrhea
- decrease in effective circulating volume (e.g. tachycardia, HTN, oliguria, etc.)
- foamy urine is a possible sign of proteinuria

Daily protein excretion can be estimated from a random urine protein/creatinine ratio

Investigations

- urine
  - urine dipstick (3 to 4+ proteinuria, microscopic hematuria) and microscopy (oval fat bodies, hyaline casts)
  - first morning urine protein/creatinine ratio (>300 mg/mmol)
- blood work
  - diagnostic: hypoalbuminemia (<25 g/L), hyperlipidemia/hypercholesterolemia (total cholesterol >5 mmol/L)
  - secondary: electrolytes (hypocalcemia, hyperkalemia, hyponatremia), renal function (↑ BUN and Cr), coagulation profile (↓ PTT)
  - appropriate investigations to rule out secondary causes: CBC, blood smear, C3/C4, ANA, hepatitis B/C titres, ASOT, HIV serology, etc.
- consider renal biopsy if: HTN, gross hematuria, ↓ renal function, low serum C3/C4, no response to steroids after 4 wk of therapy, frequent relapses (>2 in 6 mo), presentation before first yr of life (high likelihood of congenital nephrotic syndrome), presentation ≥12 yr (rule out more serious renal pathology than MCD)

Side Effects of Long-Term Steroid Use

GOOD CUSHINGS
Growth impairment
Obesity
Osteoporosis
Dorsal hump

Changes in behaviour
Ulcers
Striae
Hypertension
Immunosuppression; infection
Need to eat
Glucose elevation
Salt and water retention

Management

- MCD: oral prednisone 2 mg/kg/d (or equivalent) for up to 12 wk → varicella status should be known before starting
- consider cytotoxic agents, immunomodulators, or high-dose pulse corticosteroid if steroid resistant
- symptomatic
  - edema: salt and fluid restriction, possibly diuretic (avoid if significant intravascular depletion); furosemide + albumin for anasarca
  - hyperlipidemia: generally resolves with remission; limit dietary fat intake; consider statin therapy if persistently nephrotic
  - hypoalbuminemia: IV albumin and furosemide not routinely given; consider if refractory edema
  - abnormal BP: control BP; fluid resuscitation if severe intravascular depletion; ACEI or ARBs for persistent HTN
- diet: no added salt; monitor caloric intake and supplement with Ca^{2+} and vitamin D if on corticosteroids
- daily weights and BP to assess therapeutic progress
- secondary infections: treat with appropriate antimicrobials; antibiotic prophylaxis not recommended; pneumococcal vaccine at diagnosis and varicella vaccine after remission; varicella Ig + acyclovir if exposed while on corticosteroids
- secondary hypercoagulability: mobilize, avoid hemoconcentration due to hypovolemia, prompt sepsis treatment; heparin if thrombi occur

Prognosis

- generally good: 80% of children responsive to corticosteroids
- up to 2/3 experience relapse, often multiple times; sustained remission with normal kidney function usually by adolescence
- complications: ↑ risk of infections (spontaneous peritonitis, cellulitis, sepsis); hypercoagulability due to decreased intravascular volume and antithrombin III depletion (PE, renal vein thrombosis); intravascular volume depletion, leading to hypotension, shock, renal failure; drug side effects

Hypertension in Childhood

Definition

- HTN: sBP and/or dBP ≥95th percentile for sex, age, and height on ≥3 occasions
- pre-HTN: sBP and/or dBP ≥90th percentile but <95th percentile or BP ≥120/80 irrespective of age, sex, and height

Table 41. 95th Percentile Blood Pressures (mmHg)

	Female		Male	
Age (Yr)	**50th Percentile for Height**	**75th Percentile for Height**	**50th Percentile for Height**	**75th Percentile for Height**
1	103/60	104/61	103/55	104/56
6	111/72	112/73	111/71	112/72
12	122/78	124/79	121/78	124/78
17	127/81	128/82	135/85	137/86

Flynn JT, Kaelber DC, Baher-Smith CM, et al. Clinical practice guideline for screening and management of high blood pressure in children and adolescents. Pediatrics 2017;140(3):e20171904

Epidemiology

- prevalence: 3-5% for HTN, 7-10% for pre-HTN; M>F
- increasing prevalence of pre-HTN over the last 25+ yr

Etiology

- primary HTN
  - diagnosis of exclusion
  - most common in older children (≥10 yr), especially if positive family history, overweight, and only mild HTN
  - responsible for ~90% of cases of HTN in adolescents, rarely in young children
- secondary HTN
  - identifiable cause of HTN (most likely etiology depends on age)
  - responsible for majority of childhood HTN
- always consider white coat HTN for all ages

Table 42. Etiology of HTN by Age Group

System	Neonates	1 mo-6 yr	7-12 yr	>13 yr
Endocrine/Metabolic	CAH	Wilms' tumour (↑ renin) Neuroblastoma (↑ catecholamines)	Endocrinopathies* Essential hypertension	Endocrinopathies* Essential hypertension
Renal	Congenital renal disease Renal artery thrombosis	Renal parenchymal disease	Renal parenchymal disease	Renal parenchymal disease
Vascular	Coarctation of the aorta Renal artery thrombosis	Coarctation of the aorta RAS	Renovascular abnormalities	Renovascular disease
Drugs		Corticosteroids Cyclosporine and tacrolimus	Corticosteroids OCP Cyclosporine and tacrolimus	Corticosteroids OCP Cyclosporine and tacrolimus Recreational drugs (amphetamines, cocaine, etc.)

*Note: may include hyperthyroidism, hyperparathyroidism, Cushing's syndrome, primary hyperaldosteronism/Conn's syndrome, pheochromocytoma

Risk Factors

- primary HTN: obesity, male sex, African ethnicity, family history of HTN, LBW
- secondary HTN: prepubertal age, no family history of HTN, history of renal disease, family history of autoimmune disease

Clinical Features

- often asymptomatic, but can include FTT, fatigue, epistaxis
- symptoms of hypertensive emergency
  - neurologic: headache, seizures, focal complaints, change in mental status, visual disturbances
  - cardiovascular: symptoms of MI or heart failure (chest pain, palpitations, cough, SOB)
- symptoms of secondary HTN: guided by etiology; ask about medications and recreational drugs (current and past)
- physical exam: upper and lower limb BP with correct cuff size, BMI, full neurologic exam, ophthalmoscopy, precordial exam, peripheral pulses, perfusion status

Signs of Secondary HTN
- Edema (renal parenchymal disease)
- Abdominal or renal bruit (RAS)
- Differential 4 limb BP/diminished femoral pulses (coarctation)
- Abdominal mass (Wilms', neuroblastoma)
- Goitre/skin changes (hyperthyroidism)
- Ambiguous genitalia (CAH)

Paediatric BP Calculation
sBP= age x 2 + 90
dBP= 2/3 x sBP

Investigations
- laboratory
  - BUN, creatinine, electrolytes, urinalysis, fasting lipid profile
  - obese patients: HbA1c, AST, ALT
  - further investigations based on history and physical
- imaging: renal ultrasound (with doppler), echo (coarctation, LVH)
- 24 h ambulatory blood pressure monitoring (if assessing white coat HTN)

Management
- treat underlying cause
- non-pharmacologic: modify concurrent cardiovascular risk factors (e.g. weight reduction, exercise, salt restriction, smoking and drug cessation)
- pharmacologic: gradual lowering of BP using thiazide diuretics; no antihypertensives have been formally studied in children; if hypertensive emergency use hydralazine, labetalol, sodium nitroprusside
- management of end-organ damage (e.g. retinopathy, LVH)
- consider referral to specialist

Prognosis
- end-organ damage (similar to adults) including LVH, CHF, cerebrovascular insults, renal disease, retinopathy

Neurology

Cerebral Palsy

Definition
- non-progressive central motor impairment syndrome due to CNS anomaly or neural injury at the prenatal, perinatal, or postnatal stage
- incidence: 1.5-2.5 in 1000 live births (industrialized nations)
- life expectancy is dependent on the degree of mobility and intellectual impairment, not on severity of CNS lesion

Etiology
- no known cause identified in 1/3 of cases
- prenatal causes: TORCH infections, maternal disorders (e.g. epilepsy), congenital CNS anomaly
- perinatal causes: prematurity, LBW, ischemic stroke
- postnatal causes: infections (e.g. meningitis), asphyxia, IVH, trauma, severe jaundice

Clinical Features
- general signs: delay in motor milestones, developmental delay, learning disabilities, visual/hearing impairment, seizures, microcephaly, uncoordinated swallow (aspiration)

Table 43. Types of Cerebral Palsy

Type	Characteristics	Area of Brain Involved
Spastic (70-80%)	Truncal hypotonia in first yr Increased tone, increased reflexes, clonus Can affect one limb (monoplegia), one side of body (hemiplegia), both legs (diplegia), or both arms and legs (quadriplegia)	UMN of pyramidal tract Hemiplegia most commonly caused by middle cerebral artery stroke Diplegia associated with periventricular leukomalacia in premature babies Quadriplegia associated with HIE (asphyxia), higher incidence of intellectual disability
Athetoid/Dyskinetic (10-15%)	Athetosis ± chorea or hypotonia Can involve face, tongue (results in dysarthria)	Basal ganglia (may be associated with kernicterus)
Ataxic (<5%)	Poor coordination, poor balance (wide based gait) Can have intention tremor	Cerebellum
Mixed (10-15%)	More than one of the above motor patterns	Some combination of the above

Investigations
- neuroimaging (MRI), may include metabolic screen, chromosome studies, serology, EMG, EEG (if seizures), ophthalmology assessment, audiology assessment

Management
- maximize potential through multidisciplinary services (e.g. primary care physician, OT, PT, SLP, school supports, etc.)
- orthopaedic and/or neurosurgical management (e.g. dislocations, contractures, rhizotomy)
- management of symptoms: spasticity (baclofen, Botox®), constipation (stool softeners)

Febrile Seizures

Epidemiology
- most common cause of seizures in children (3-5% of children)
- M>F; age 6 mo-6 yr

Clinical Features
- otherwise well, neurotypical child
- fever often with associated illness (source of fever), family history, past history of simple febrile seizures
- no evidence of CNS infection/inflammation before or after seizure; no history of non-febrile seizures

Table 44. Comparison of Typical and Atypical Febrile Seizures

Simple/Typical (70-80%)	Complex/Atypical (20-30%)
All of the following: Duration <15 min (95% <5 min) Generalized tonic-clonic No recurrence in 24 h period No neurological impairment or developmental delay before or after seizure Very small risk of developing epilepsy (2% vs. 1% in general population)	At least one of the following: Duration >15 min Focal onset or focal features during seizure Recurrent seizures (>1 in 24 h period) Previous neurological impairment or neurological deficit after seizure Increased risk of developing epilepsy

Investigations
- history: determine focus of fever, description of seizure, medications, trauma history, developmental history, FMHx
- physical exam: LOC, signs of meningitis, neurological exam, head circumference, focus of infection
- septic workup including LP if suspecting meningitis (strongly consider if child <12 mo; consider if child is 12-18 mo; only if meningeal signs present in child >18 mo)
- if typical febrile seizure, investigations only for determining focus of fever
- EEG/CT/MRI brain not warranted unless atypical febrile seizure or abnormal neurologic findings

Management
- counsel and reassure patient and parents
  - febrile seizures do not cause brain damage
  - very small risk of developing epilepsy in simple febrile seizures
  - 33% chance of recurrence (mostly within 1 yr of first seizure and in children <1 yr)
- antipyretics and fluids for comfort (though neither prevent seizure)
- no prophylaxis with antiepileptic drugs
- if high-risk for recurrent or prolonged seizures, have rectal or sublingual lorazepam at home
- treat underlying cause of fever

Hypotonia

Definition
- decreased resistance to passive movements – "floppy baby"

Differential Diagnosis
- central: genetic (DS, Prader-Willi, Fragile X syndrome), metabolic (hypoglycemia, kernicterus), perinatal problems (HIE, ICH), endocrine (hypothyroidism, hypopituitarism), systemic illness (TORCH infection, sepsis, dehydration), CNS malformations, dysmorphic syndromes
- peripheral: motor neuron (spinal muscular atrophy, polio), peripheral nerve (Charcot-Marie-Tooth syndrome), neuromuscular junction (myasthenia gravis), muscle fibre (mitochondrial myopathy, muscular dystrophy, myotonic dystrophy)

Clinical Features
- history: GA, onset/progression, family history of neuromuscular abnormalities, obstetrical history, birth trauma
- physical exam:
  - general: dysmorphic features, weight, length, head circumference
  - MSK: postural movements including traction response, axillary suspension, ventral suspension (see Figure 17)
  - neurological: spontaneous posture, muscle bulk, presence of fasciculations
    - UMN lesion (60-80%): increased deep tendon reflexes and clonus; floppy and strong; + Babinski; neonatal reflexes present
    - LMN lesion (15-30%): lack of deep tendon reflexes; floppy and weak; - Babinski; neonatal reflexes absent

Causes of Hypotonia that Respond to Rapid Treatment

H4I2SAD
Hypokalemia
Hypermagnesemia
Hypoglycemia
Hydrocephalus
Infection
ICH
Seizure
Acidemia
Drugs/toxins

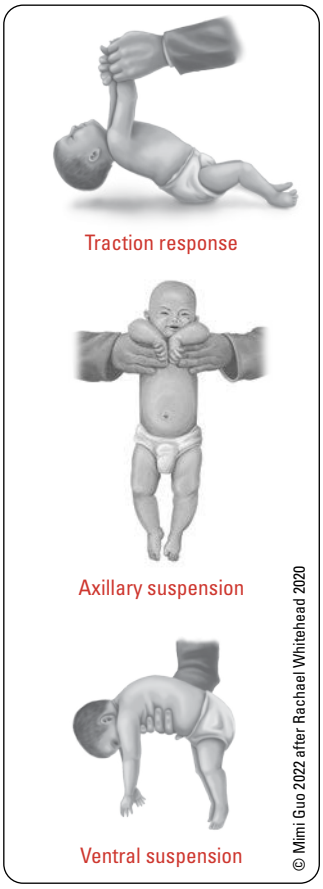

Figure 17. Hypotonia

Investigations
- rule out systemic disorders (e.g. electrolytes, ABG, blood glucose, CK, and serum/urine investigations for multiple etiologies including mitochondrial causes)
- neuroimaging: MRI/MRA when indicated
- EMG, muscle biopsy/NCS
- chromosome analysis, genetic testing, metabolic testing, neuromuscular testing

Management
- depends on etiology: some treatments available for specific diagnosis
- counsel parents on prognosis and genetic implications
- refer patients for specialized care including: rehabilitation, OT, PT, assess feeding ability

Neurocutaneous Syndromes

Definition
- characterized by skin colour changes and tendency to form tumours of the CNS, PNS, viscera, and skin

In neurocutaneous syndromes, the younger the child at presentation, the more likely they are to develop intellectual disability

NEUROFIBROMATOSIS TYPE I (VON RECKLINGHAUSEN DISEASE)
- autosomal dominant but 50% are the result of new mutations
- incidence 1 in 3000, mutation in NF1 gene on 17q11.2 (codes for neurofibromin protein)
- learning disorders, abnormal speech development, and seizures are common
- diagnosis of NF-1 requires 2 or more of:
  - ≥6 café-au-lait spots (>5 mm if prepubertal, >1.5 cm if postpubertal)
  - ≥2 neurofibromas of any type or one plexiform neurofibroma
  - ≥2 Lisch nodules (hamartomas of the iris)
  - optic glioma
  - freckling in the axillary or inguinal region
  - a distinctive bony lesion (e.g. sphenoid dysplasia, cortical thinning of long bones)
  - a first degree relative with confirmed NF-1
- management involves treatment of disease manifestations as they occur, as well as genetic counselling, OT, PT, and speech therapy as needed

NEUROFIBROMATOSIS TYPE II
- autosomal dominant but >50% are the result of new mutations
- incidence 1 in 33000, mutation in NF2 gene on chromosome 22 (codes for merlin protein)
- characterized by predisposition to form intracranial, spinal tumours
- diagnosed when (a) bilateral vestibular schwannomas are found, OR (b) patient has a first-degree relative with NF-2 AND EITHER unilateral vestibular schwannoma OR any two of the following: meningioma, glioma, schwannoma, neurofibroma, posterior subcapsular lenticular opacities
- treatment consists of monitoring for tumour development and surgery

Recurrent Headache

- see Neurology, N46

Differential Diagnosis
- primary headache: tension, migraine, cluster
- secondary headache: see Neurology, N47
- anxiety or life stress (e.g. recent move, bullying, parents' divorce, domestic abuse)

General Assessment
- if unremarkable history and physical exam, most likely diagnosis is migraine or tension headache
- CT or MRI if red flags present
- inquire about level of disability, academic performance, after-school activities

Headache – Red Flags
- First and worst headache of their life
- Sudden onset
- Focal neurological deficits
- Constitutional symptoms
- Worse in morning
- Worse with bending over, coughing, straining
- Change in LOC
- Sudden mood changes
- Pain that wakes patient
- Fatigue
- Affecting school attendance

Seizure Disorders

- see Neurology, N18

Differential Diagnosis of Seizures in Children
- benign febrile seizure
- CNS: infection, tumour, HIE, trauma, hemorrhage
- metabolic: hypoglycemia, hypocalcemia, hyponatremia
- idiopathic epilepsy and epileptic syndromes
- others: neurocutaneous syndromes, AVM, drug ingestions/withdrawal
- seizure mimics

Heart problems, such as long QT syndrome and hypertrophic cardiomyopathy, are often misdiagnosed as epilepsy. Include cardiac causes of syncope in your differential diagnosis, particularly when the episodes occur during physical activity

Investigations
- lab tests: CBC, electrolytes, calcium, magnesium, glucose
- toxicology screen
- EEG
- CT/MRI if indicated (focal neurological deficit or has not returned to baseline several hours after seizure)
- consider LP if first-time non-febrile seizure (not indicated for determining recurrence risk of benign febrile seizures, seizure type, or epileptic syndrome)

Seizure Mimics
- Benign paroxysmal vertigo
- Breath holding
- Hypoglycemia
- Narcolepsy
- Night terror
- Pseudoseizure
- Syncope
- TIA
- Tic

CHILDHOOD EPILEPSY SYNDROMES

Infantile Spasms
- paediatric emergency as can lead to developmental regression in previously well child and therefore must be identified and investigated early
- brief, repeated symmetric contractions of neck, trunk, and extremities (flexion and extension) lasting 10-30 s
- occur in clusters; often associated with developmental delay; onset 4-8 mo
- 20% unknown etiology (usually good response to treatment); 80% due to metabolic or developmental abnormalities, encephalopathies, or associated with neurocutaneous syndromes (usually poor response to treatment)
- can develop into West syndrome (infantile spasms, psychomotor developmental arrest, and hypsarrhythmia) or Lennox-Gastaut (see below)
- typical EEG: hypsarrhythmia (high voltage slow waves, spikes and polyspikes, background disorganization)
- management: ACTH, vigabatrin, benzodiazepines

Ketogenic Diet and Other Dietary Treatments for Epilepsy
Cochrane DB Syst Rev 2012;3:CD001903
Purpose: Systematic review of all studies of ketogenic and related diets. Included the review of 4 RCTs, 6 prospective studies, and 5 retrospective studies.
Population: Adults and children with diagnosed epilepsy of any type.
Intervention: Ketogenic diet, control (placebo diet, any treatment with known antiepileptic properties). Main Outcome Measure: Seizure control at 3, 6, 12 mo.
Results: Studies showed a response rate of at least 38-50% seizure reduction at 3 mo. This response was maintained for up to a year. A range of side effects were reported. The most frequent were gastrointestinal effects (30%).
Conclusion: The ketogenic diet is a valid option for people with medically-intractable epilepsy.

Lennox-Gastaut
- characterized by triad of:
  1. multiple seizure types
  2. diffuse cognitive dysfunction
  3. slow generalized spike and slow wave EEG
- onset commonly 3-5 yr
- seen with underlying encephalopathy and brain malformations
- management: valproic acid, benzodiazepines, vagal nerve stimulator, and ketogenic diet; however, response often poor

Juvenile Myoclonic Epilepsy (Janz Syndrome)
- myoclonus particularly in morning; frequently presents as generalized tonic-clonic seizures
- adolescent onset (12-16 yr); autosomal dominant with variable penetrance
- typical EEG: 3.5-6 Hz irregular spike and wave, increased with photic stimulation
- management: lifelong treatment (valproic acid); excellent prognosis

Childhood Absence Epilepsy
- multiple daily absence seizures lasting <30 s without postictal state that may resolve spontaneously or become generalized in adolescence
- peak age of onset 6-7 yr, F>M, strong genetic predisposition
- typical EEG: 3 Hz spike and wave
- management: valproic acid or ethosuximide

Benign Focal Epilepsy of Childhood with Rolandic/Centrotemporal Spikes
- focal motor seizures involving tongue, mouth, face, and upper extremity usually occurring in sleep-wake transition states; remains conscious, but aphasic postictally
- onset peaks at 5-10 yr; 16% of all non-febrile seizures; remits spontaneously in adolescence without sequelae
- typical EEG: repetitive spikes in centrotemporal area with normal background
- management: frequent seizures controlled by carbamazepine, no medication if infrequent seizures

General Approach to Treatment
- education for patient and parents including education and precautions in daily life (e.g. buddy system, showers instead of baths)
- medication
  - initiate: treat with drug appropriate to seizure type; often if >2 unprovoked afebrile seizures within 6-12 mo
  - optimize: start with one drug and increase dosage until seizures controlled
  - if no effect, switch over to another before adding a second antiepileptic drug
- continue antiepileptic drug therapy until patient free of seizures for >2 yr, then wean over 4-6 mo
- ketogenic diet (high fat diet): used in patients who do not respond to polytherapy or who do not wish to take medication (valproic acid contraindicated in conjunction with ketogenic diet because may increase hepatotoxicity)
- legal obligation to report to Ministry of Transportation if patient wishes to drive

Generalized and Partial Seizures
- see Neurology, N18

Respirology

Asthma

Definition
- see Respirology, R7
- inflammatory disorder of the airways characterized by recurrent episodes of reversible small airway obstruction resulting from airway hyperresponsiveness to endogenous and exogenous stimuli
- in Canada, the lifetime prevalence in childhood is 10-15% and presents most often in early childhood
- associated with other atopic diseases such as allergies and/or atopic dermatitis

Clinical Features
- episodic bouts of wheezing, dyspnea, tachypnea, cough (usually at night/early morning, with activity, or with cold exposure)
- physical exam may reveal hyper-resonant chest, prolonged expiration, wheeze, or 'quiet'/tight chest when airflow limited
- symptoms may be exacerbated by "triggers": URTI (viral or Mycoplasma), weather (e.g. cold exposure, humidity changes), allergens (e.g. pets), irritants (e.g. cigarette smoke), exercise, emotional stress, drugs (e.g. ASA, β-blockers)

Classification
- mild: occasional attacks of wheezing or coughing (<2/wk); symptoms respond quickly to inhaled bronchodilators alone and seldomly need inhaled corticosteroids
- moderate: more frequent episodes with symptoms persisting and chronic cough; decreased exercise tolerance; requires inhaled bronchodilator and inhaled corticosteroids; sometimes needs systemic corticosteroids
- severe: daily and nocturnal symptoms; frequent ED visits and hospitalizations; usually needs systemic corticosteroids

Management
- acute
  - O_2 (keep O_2 saturation >94%) and fluids if dehydrated
  - β2-agonists: salbutamol (Ventolin®) MDI + spacer (nebulized or IV in very severe episodes with impending respiratory failure), 5 puffs (<20 kg) or 10 puffs (>20 kg) q20 min for first h
  - ipratropium bromide (Atrovent®) if severe: MDI + spacer, 3 puffs (<20 kg) or 6 puffs (>20 kg) q20 min with salbutamol, or add to first 3 salbutamol masks (0.25 mg if <20 kg, 0.5 mg if >20 kg)
  - steroids: prednisone (1-2 mg/kg/d x5 d) or dexamethasone (0.3 mg/kg/d x5 d or 0.6 mg/kg/d x2 d); in severe disease, use IV steroids
  - if no response, add magnesium sulphate
  - continue to observe; can discharge patient if asymptomatic for 2-4 h after last dose
  - discharge home with inhaled corticosteroids (e.g. fluticasone)
- chronic
  - education, emotional support, avoid triggers, develop an "action plan", exercise program (e.g. swimming)
  - monitor respiratory function with peak flow metre (improves self-awareness of status)
  - reliever therapy: short acting β2-agonists (e.g. salbutamol)
  - controller therapy (first line therapy for all children): low dose daily inhaled corticosteroids
  - second line therapy for children <12 yr: moderate dose of daily inhaled corticosteroids
  - second line therapy for children >12 yr: leukotriene receptor antagonist OR long acting β2-agonist in conjunction with low dose inhaled corticosteroids; leukotriene receptor antagonist monotherapy may be considered an alternative second line therapy
  - severe asthma unresponsive to first and second line treatments: injection immunotherapy
  - aerochamber for children using daily inhaled corticosteroids
- indications for hospitalization
  - ongoing need for supplemental O_2
  - persistently increased work of breathing
  - β2-agonists are needed more often than q4 h after 4-8 h of conventional treatment
  - patient deteriorates while on systemic steroids

Updated Guidance for Palivizumab Prophylaxis among Infants and Young Children at Increased Risk of Hospitalization for Respiratory Syncytial Virus Infection
Pediatrics 2014;134(2):415-420
Palivizumab prophylaxis is recommended for the first yr of life for infants born before 29 wk gestation, and preterm infants with chronic lung disease of maturity (born at <32 wk gestation and requiring >21% oxygen for at least 28 d after birth). Such prophylaxis may be administered in the first yr of life to infants with hemodynamically significant heart disease, and a maximum of 5 monthly 15 mg/kg doses may be administered during the RSV season to infants requiring it; infants born during the RSV season may need fewer doses. Prophylaxis may be considered in the first yr of life for children with pulmonary abnormalities or neuromuscular disease impairing the ability to clear secretions from the upper airway, and may be considered for children younger than 24 mo who are profoundly immunocompromised during the RSV season. Palivizumab prophylaxis is only recommended in the second year of life for children who required at least 28 d of supplemental oxygen after birth with ongoing medical intervention needs. Monthly prophylaxis should be discontinued in children experiencing breakthrough RSV hospitalizations. Insufficient evidence exists to support the use of prophylaxis for children with cystic fibrosis or Down's syndrome.

Canadian Paediatric Asthma Consensus Guidelines for Assessing Adequate Control of Asthma
CMAJ 2005;173(6 Suppl):S12-14
- Daytime symptoms <4 d/wk
- Night time symptoms <1 night/wk
- Normal physical activity
- Mild and infrequent exacerbations
- No work/school absenteeism
- Need for β-agonist <4 doses/wk
- FEV1 or peak expiratory flow ≥90% of personal best
- Peak expiratory flow diurnal variation <10-15%

Bronchiolitis

Definition
- LRTI, usually in children <2 yr, that has wheezing and signs of respiratory distress

Epidemiology
- the most common LRTI in infants, affects 50% of children in first 2 yr of life; peak incidence at 6 mo, winter or early spring
- increased incidence of asthma later in life

Etiology
- RSV (>50%), parainfluenza, influenza, rhinovirus, adenovirus, M. pneumoniae (rare)

Clinical Features
- prodrome of URTI with cough and/or rhinorrhea, possible fever
- feeding difficulties, irritability
- wheezing, crackles, respiratory distress, tachypnea, tachycardia, retractions, poor air entry; symptoms often peak at 3-4 d

Investigations
- routine investigations are not required when bronchiolitis is suspected (Choosing Wisely)
- CXR (only in poor response to therapy or atypical disease): air trapping, peribronchial thickening, atelectasis, increased linear markings

Management
- self-limiting disease with peak symptoms usually lasting 2-3 wk
- mild to moderate distress
  - supportive: PO or IV hydration, oral/nasal suctioning as needed, antipyretics for fever, regular or humidified high flow O_2
- severe distress
  - as above ± humidified high flow O_2 or intubation and ventilation as needed
  - consider palivizumab (targets F-glycoprotein of RSV) as a prophylaxis in high-risk infants: bronchopulmonary dysplasia, CHD, congenital lung disease, immunodeficient
- bronchodilators, corticosteroids, and antibiotics have no therapeutic value (unless there is secondary bacterial pneumonia)
- indications for hospitalization
  - hypoxia: O_2 saturation <92% on initial presentation or increasing O_2 requirements
  - signs of severe distress (tachypnea >80/min, tachycardia >180/min, grunting, nasal flaring, marked chest retractions, lethargy) despite several salbutamol masks
  - past history of chronic lung disease, hemodynamically significant cardiac disease, neuromuscular problem, immunocompromised
  - high-risk infants: history of prematurity (<34 wk), weight <4 kg, age <7 wk
  - significant feeding problems
  - socioeconomic barriers to improvement (e.g. inadequate care at home)

Bronchodilators for Bronchiolitis
Cochrane DB Syst Rev 2010;12:CD001266
Purpose: To assess the effects of bronchodilators in infants with acute bronchiolitis.
Methods: Meta-analysis of placebo-controlled RCTs evaluating bronchodilators for bronchiolitis. Oxygen saturation was the main outcome.
Results: 30 trials with 1992 infants with bronchiolitis were included. Oxygen saturation did not improve with bronchodilators (mean difference (MD) -0.43, 95% CI -0.92 to 0.06). Neither outpatient (11.9% vs. 15.9%, OR 0.75, 95% CI 1.21) nor inpatient (MD 0.06, 95% CI -0.27 to 0.39) reduced hospitalization rates. Effects on oximetry seen in inpatients (MD -0.62, 95% CI -1.40 to 0.16) were slightly larger than for outpatients (MD -0.25, 95% CI -0.61 to 0.11). No change in average clinical score was seen in inpatients (standardized MD -0.14, 95% CI -0.41 to 0.12), while a statistically significant decrease was seen in outpatients (MD -0.42, 95% CI -0.79 to -0.06). Adverse events included tachycardia, oxygen desaturation, and tremors.
Conclusions: Bronchodilators do not improve oxygen saturation, rates of hospital admission, duration of hospitalizations, or durations to resolution of illness. They are not considered effective in routine management of bronchiolitis, especially given their adverse effects.

Children with bronchiolitis do not respond to salbutamol, ipratropium bromide (Atrovent®), or steroids

Cystic Fibrosis

- see Respirology, R12

Etiology
- 1 in 3000 live births, mostly White individuals
- autosomal recessive, mutation in CFTR gene found on chromosome 7 (ΔF508 mutation in 70%, but >1600 different mutations identified) resulting in a dysfunctional chloride channel on the apical membrane of cells
- leads to relative dehydration of airway secretions, resulting in impaired mucociliary transport and airway obstruction

Clinical Features
- neonatal: meconium ileus, prolonged jaundice, antenatal bowel perforation
- infancy: pancreatic insufficiency with steatorrhea and FTT (despite voracious appetite), anemia, hypoproteinemia, hyponatremia
- childhood: heat intolerance, wheezing or chronic cough, recurrent chest infections (*S. aureus, P. aeruginosa, H. influenzae*), hemoptysis, nasal polyps, distal intestinal obstruction syndrome, rectal prolapse, clubbing of fingers
- older patients: COPD, infertility (males), decreased fertility (female)

CF Presenting Signs

CF PANCREAS
Chronic cough and wheezing
FTT
Pancreatic insufficiency (symptoms of malabsorption such as steatorrhea)
Alkalosis and hypotonic dehydration
Neonatal intestinal obstruction (meconium ileus)/Nasal polyps
Clubbing of fingers/Chest radiograph with characteristic changes
Rectal prolapse
Electrolyte elevation in sweat, salty skin
Absence or congenital atresia of vas deferens
Sputum with *S. aureus* or *P. aeruginosa* (mucoid)

Investigations
- neonatal screening
- sweat chloride test x 2 (>60 mEq/L)
  - false positive tests: malnutrition, atopic dermatitis, hypothyroidism, hypoparathyroidism, GSD, adrenal insufficiency, G6PD, Klinefelter syndrome, technical issues, autonomic dysfunction, familial cholestasis syndrome
  - false negative tests: technical problem with test, malnutrition, skin edema, mineralocorticoids
- CFTR gene mutation analysis: genetic screening panels or gene sequencing if clinically suspicious for rare mutation, useful when sweat chloride test is equivocal
- disease often detected during newborn genetic screening; positive result requires DNA testing and subsequent sweat chloride testing

Management
- nutritional counselling: high calorie diet, pancreatic enzyme replacements, fat soluble vitamin supplements
- management of chest disease: physiotherapy, postural drainage, exercise, bronchodilators, aerosolized DNase and inhaled hypertonic saline, antibiotics (e.g. cephalosporin, cloxacillin, ciprofloxacin, inhaled tobramycin depending on sputum C&S), lung transplantation
- genetic counselling

Complications
- respiratory failure, pneumothorax (poor prognostic sign), cor pulmonale (late), pancreatic fibrosis with DM, gallstones, cirrhosis with portal HTN, infertility (male), recurrent respiratory infections
- early death (current median survival in Canada is 46.6 yr)

Pneumonia

Etiology
- inflammation of pulmonary tissue, associated with consolidation of alveolar spaces

Clinical Features
- incidence is greatest in first year of life with viral causes being most common in children <5 yr
- fever, cough, tachypnea
- CXR: diffuse, streaky infiltrates bilaterally
- bacterial causes may present with cough, fever, chills, dyspnea, more dramatic CXR changes (e.g. lobar consolidation, pleural effusion)

Management
- supportive therapy: hydration, antipyretics, humidified O_2

Table 45. Common Causes and Treatment of Community-Acquired Pneumonia

Age	Bacterial	Viral	Treatment
Neonates	GBS *E. coli* *Listeria*	HSV CMV Enterovirus	Ampicillin AND gentamicin
1-3 mo	*S. aureus* *S. pneumoniae* *Chlamydia trachomatis*	RSV Influenza Human metapneumovirus Adenovirus Parainfluenza virus	Ampicillin OR ceftriaxone Azithromycin (if *Chlamydia trachomatis* suspected)
3 mo-5 yr	*S. pneumoniae* *S. aureus* *S. pyogenes*	RSV Influenza Human metapneumovirus Adenovirus Parainfluenza virus	Amoxicillin OR ampicillin OR ceftriaxone
>5 yr	*S. pneumoniae* *Mycoplasma pneumoniae* *Chlamydophila pneumoniae*	Influenza	Amoxicillin OR ampicillin OR ceftriaxone Azithromycin OR clarithromycin (if *Mycoplasma/Chlamydophila pneumoniae* suspected)

Respiratory Distress

APPROACH TO DYSPNEA
- determine if patient is sick or not sick; ABCs
- history: onset, previous episodes, precipitating events, associated symptoms, past medical/family history of respiratory disease
- physical exam: vitals, SpO_2, evidence of cyanosis, respiratory, cardiovascular
- investigations: CBC and differential, electrolytes, BUN, Cr, NP swab, ABG, CXR, ECG (based on clinical findings)

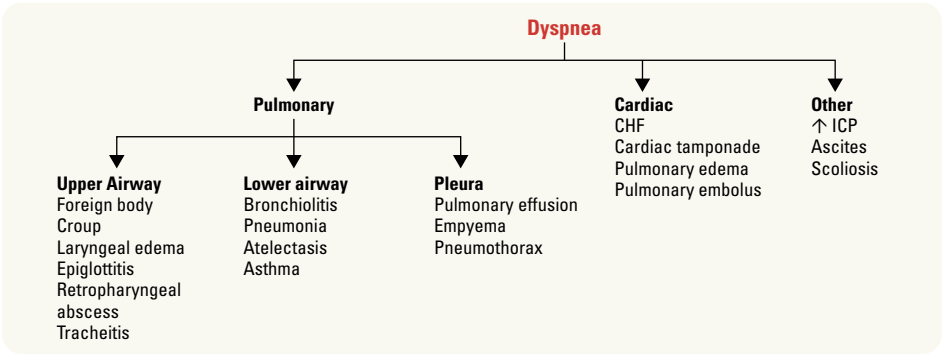

Figure 18. Approach to dyspnea in childhood

APPROACH TO WHEEZING

- caused by obstruction of airways below thoracic inlet

Differential Diagnosis of Wheezing

- common: asthma (recurrent wheezing episodes, identifiable triggers, typically >6 yr), bronchiolitis (first episode of wheezing, usually <1 yr), recurrent aspiration (often neurological impairment), pneumonia (fever, cough, malaise)
- uncommon: foreign body (acute unilateral wheezing and coughing), CF (prolonged wheezing, unresponsive to therapy), bronchopulmonary dysplasia (often develops after prolonged ventilation in the newborn)
- rare: CHF, mediastinal mass, bronchiolitis obliterans, tracheobronchial anomalies

APPROACH TO STRIDOR

- caused by obstruction above the thoracic inlet and may also present with hoarseness and suprasternal retractions
- stridor at rest is an emergency
- differential diagnosis of stridor: croup, bacterial tracheitis, epiglottitis, foreign body aspiration, subglottic stenosis (congenital or iatrogenic), laryngomalacia/tracheomalacia (collapse of airway cartilage on inspiration), retropharyngeal abscess

Table 46. Common Upper Respiratory Tract Diseases in Children

	Croup (Laryngotracheitis)	Bacterial Tracheitis	Epiglottitis	Choanal Atresia
Affected Site	Subglottis	Trachea	Supraglottis	Posterior nasal aperture(s)
Epidemiology	Common in children 6-36 mo Increased incidence in fall and winter months	Rare Usually seen in children 3 mo to 6 yr	Decreased incidence due to Hib vaccination Common in children 2-6 yr	1 in 7000 live births 2 in 3 are unilateral F>M
Etiology	Parainfluenza (75%) Influenza A and B RSV Adenovirus	*S. aureus* *S. pneumoniae* *H. influenzae* α-hemolytic *Strep* *M. catarrhalis*	*H. influenzae* *S. pneumoniae* β-hemolytic *Strep* *S. aureus*	Oronasal membrane persists preventing the nose joining the oropharynx
Clinical Presentation	Non-toxic appearance Barking cough Stridor Viral prodrome (rhinorrhea, pharyngitis, cough ± low-grade fever) Hoarseness	Toxic appearance Rapid progression Cough Biphasic stridor No response to corticosteroids and nebulized epinephrine	Toxic appearance Rapid progression 4 **D**s: **d**rooling, **d**ysphagia, **d**ysphonia, **d**istress Stridor Tripod position No cough Fever (>39°C)	Unilateral: diagnosed later in life, unilateral discharge or obstruction Bilateral: diagnosed during infancy, noisy breathing, cyanosis that worsens with feeds and improves when crying
Investigations	Clinical diagnosis CXR: "steeple sign" from subglottic narrowing	Clinical diagnosis Endoscopy: definitive diagnosis	Clinical diagnosis Perform physical exam cautiously to avoid exacerbating respiratory distress	Inability to pass NG tube through nares CT: definitive diagnosis
Management	Mild-to-moderate: corticosteroids, supportive care Severe: corticosteroids, nebulized epinephrine, humidified oxygen, intubation if necessary	Intubation IV antibiotics	Intubation IV antibiotics	Acute (bilateral choanal atresia): place oral airway, initiate gavage feedings Long-term: referral to otolaryngology

Rheumatology

Growing Pains

Epidemiology
- age 2-12 yr, M=F

Clinical Features
- diagnosis of exclusion
- intermittent, non-articular pain in childhood with normal physical exam findings
- pain at night, often bilateral and limited to the calf, shin, or thigh; typically short-lived
- relieved by heat, massage, mild analgesics
- child is well, asymptomatic during the day, no functional limitations
- possible family history of growing pains

Management
- lab investigations not necessary if typical presentation; reassurance and supportive management

Juvenile Idiopathic Arthritis

- a heterogenous group of conditions characterized by persistent arthritis in children <16 yr
- diagnosis: arthritis in ≥1 joint(s); duration ≥6 wk; onset age <16 yr; exclusion of other causes of arthritis; classification defined by features/number of joints affected in the first 6 mo of onset

Systemic Arthritis (Still's Disease)
- onset at any age, M=F
- once or twice daily fever spikes (>38.5°C) ≥2 d/wk with temperature returning rapidly to baseline; children usually acutely unwell during fever episodes
- extra-articular features: erythematous "salmon-coloured" maculopapular rash, lymphadenopathy, hepatosplenomegaly, leukocytosis, thrombocytosis, anemia, serositis, pericarditis
- arthritis may occur weeks to months later
- high ESR, CRP, WBC, platelet count

Oligoarticular Arthritis (1-4 joints)
- most common type of JIA
  - onset early childhood (<5 yr), F>M
- persistent: affects no more than 4 joints during the disease course
- extended: affects more than 4 joints after the first 6 mo
- typically affects large joints: knees (most common), ankles, elbows, wrists; hip involvement unusual
- ANA positive ~60-80%, RF negative
- screening eye exams for asymptomatic anterior uveitis (occurs in ~30%)
- complications: knee flexion contracture, quadriceps atrophy, leg-length discrepancy, growth disturbances, uveitis

Polyarticular Arthritis (5 or more joints)
- ANA positive in 50%, uveitis in 10%
- RF negative (more common)
  - onset: 2-4 yr and 6-12 yr, F>M
  - symmetrical involvement of large and small joints of hands and feet, TMJ, cervical spine
- RF positive
  - onset: late childhood/early adolescence, F>M
  - similar to the aggressive form of adult rheumatoid arthritis and has a similar course progressing into adulthood in most cases
  - severe, rapidly destructive, symmetrical arthritis of large and small joints
  - may have rheumatoid nodules at pressure points (elbows, knees)

Enthesitis-Related Arthritis
- onset: late childhood/adolescence, M>F
- RF negative arthritis and/or enthesitis (inflammation at the site where tendons or ligaments attach to the bone)
- weight bearing joints, especially hip and intertarsal joints, or sacroiliitis
- risk of developing ankylosing spondylitis in adulthood
- asymmetric involvement of lower limb joints, associated with HLA-B27 and development of symptomatic uveitis/iritis

Psoriatic Arthritis
- onset: 2-4 yr and 9-11 yr, F>M
- arthritis and psoriasis OR arthritis and at least two of:
  - dactylitis, nail pitting or other abnormalities, or family history of psoriasis in a 1st degree relative
  - asymmetric or symmetric small or large joint involvement (usually knees and small joints in the hands and feet)
- erythematous, scaly lesions on scalp, post-auricular area, peri-umbilicus, or over extensor surfaces of elbows and knees

Management
- goals of therapy: eliminate inflammation, prevent joint damage, promote normal growth and development as well as normal function, minimize medication toxicity
- moderate-intensity exercise (aerobic fitness, flexibility and strengthening exercises) to maintain range of motion (ROM) and muscle strength
- multidisciplinary approach: OT/PT, social work, orthopaedics, ophthalmology, rheumatology
- 1st line drug therapy: NSAIDs, intra-articular corticosteroids
- 2nd line drug therapy: DMARDs (methotrexate, sulfasalazine, leflunomide), corticosteroids (acute management of severe arthritis, systemic symptoms of JIA, topical eye drops for uveitis), biologic agents (IL-1/IL-6 inhibition for systemic arthritis, TNF antagonist for polyarticular JIA)

Limb Pain

Evaluation of Limb Pain

Table 47. Differential Diagnosis of Limb Pain

Cause	<3 yr	3-10 yr	>10 yr
Trauma	x	x	x
Infectious			
Septic arthritis	x	x	x
Osteomyelitis	x	x	x
Inflammatory			
Transient synovitis	x	x	
JIA	x	x	x
Spondyloarthritis		x	x
SLE		x	x
Dermatomyositis		x	x
HSP		x	x
Anatomic/Orthopaedic			
Legg-Calvé-Perthes disease		x	x
Slipped capital femoral epiphysis			x
Osgood-Schlatter disease			x
Neoplastic			
Leukemia	x	x	x
Neuroblastoma	x	x	
Bone tumour		x	x
Hematologic			
Hemophilia (hemarthrosis)	x	x	x
Sickle cell anemia	x	x	x
Pain Syndromes			
Growing pains		x	x
Fibromyalgia		x	x
Complex regional pain syndrome			x

Must rule out infection, malignancy, and acute orthopaedic conditions

History
- pattern of onset and progression of symptoms (including acuity and chronicity)
- morning stiffness, limp/weight-bearing status, night pain
- joint involvement (type, distribution) ± spine (axial) involvement
- extra-articular manifestations and systemic symptoms
- functional status: activities of daily living
- family history (arthritis, IBD, psoriasis, spondyloarthropathies, uveitis, bleeding disorders, sickle cell anemia)
- past medical illness, intercurrent infection, travel, sick contact history, joint injury

Physical Exam
- growth parameters
- screening examination (paediatric gait, arms, legs, spine exam)
- joint exam: inspection/palpation (swelling, erythema, warmth, tenderness, deformity), ROM
- adjacent structures (bone, tendon, muscle, skin)
- leg length
- neurologic exam

Investigations
- basic: CBC and differential, blood smear, ESR, CRP, x-ray
- as indicated: blood (ANA, RF, culture, viral/bacterial serology, CK, PTT, sickle cell screen, immunoglobulins, complement), urinalysis, synovial fluid (cell count, Gram stain, culture), TB skin test, imaging, bone marrow aspiration, slit lamp exam

Red Flags for Limb Pain
- Fever
- Pinpoint pain/tenderness
- Pain out of proportion to degree of inflammation
- Night pain
- Weight loss
- Erythema
- Unexplained fractures

Lyme Arthritis
- see Infectious Diseases, ID22
- caused by spirochete *Borrelia burgdorferi*
- incidence highest among 5-10 yr
- do not treat children <8 yr with doxycycline (may cause permanent tooth discolouration)

Reactive Arthritis
- see Rheumatology, RH27
- arthritis (typically the knee) follows bacterial infection, especially with *Salmonella, Shigella, Yersinia, Campylobacter, Chlamydia*, and most commonly *Streptococcus* (post-streptococcal reactive arthritis)
- typically resolves spontaneously
- may progress to chronic illness or Reiter's syndrome (urethritis, conjunctivitis)

Septic Arthritis and Osteomyelitis
- MEDICAL EMERGENCY: prompt intravenous antibiotics, followed by 4 wk of oral antibiotics or 4-6 wk of oral antibiotics if the hip is involved
- see Orthopaedic Surgery, OR11

Table 48. Microorganisms and Treatment Involved in Septic Arthritis/Osteomyelitis

Age	Pathogens	Treatment
Neonate	GBS, *S. aureus*, Gram negative bacilli	Cloxacillin + gentamicin OR cloxacillin + cefotaxime
Infant (1-3 mo)	*Kingella kingae*, *Strep.* spp., *Staph.* spp. Pathogens as per neonate	Cefazolin (IV), then cephalexin (PO) OR cloxacillin + cefotaxime OR cefuroxime
Child	*Kingella kingae* (<4 yr), *S. aureus* (>4 yr), *S. pneumoniae*, GAS	Cefazolin (IV), then cephalexin (PO)
Adolescent	As above; also *N. gonorrhoeae*	Ceftriaxone OR cefixime + azithromycin

GAS = group A *Strep*; GBS = group B *Strep*
Adapted from La Saux N, Canadian Paediatric Society, Infectious Diseases and Immunization Committee. Paediatr Child Health 2018;23(5):336-343

Systemic Lupus Erythematosus
- see Rheumatology, RH11
- autoimmune illness affecting multiple organ systems
- incidence 1 in 1000, more commonly age >10, F:M = 10:1
- childhood-onset SLE vs. adult-onset SLE: children have more active disease, are more likely to have renal disease, and receive more intensive drug therapy and have a poorer prognosis compared to adults

Transient Synovitis of the Hip
- benign, self-limited inflammatory joint disorder, usually occurs after URTI, pharyngitis, AOM
- key is to differentiate from septic arthritis

Epidemiology
- 3-10 yr, M>F, more common on right side

Clinical Features
- afebrile or low-grade fever; pain typically occurs in hips or knees (referred from hip) suddenly; painful limp but full ROM (pain not as pronounced as in joint or bone infections); child does not look "toxic"
  - pain is not disabling and gradually worsens over few days, can have sudden onset of symptoms
- symptoms self-resolve over 7-10 d

Investigations
- WBC within normal limits; ESR and CRP may be mildly elevated
- joint effusions may be seen on ultrasound
  - aspirate joint and examine synovial fluid if suspicious for septic arthritis
  - MRI if suspicious for osteomyelitis or periarticular pyomyositis
- diagnosis of exclusion

Management
- goal is to manage symptoms (anti-inflammatory medications and bedrest)
  - usually resolves within 24-48 h

Complications
- Legg-Calvé-Perthes disease

Vasculitides

HENOCH-SCHÖNLEIN PURPURA
- most common childhood vasculitis, peak incidence 4-10 yr, M:F=2:1
- vasculitis of small vessels
- often have history of URTI 1-3 wk before onset of symptoms

Clinical Features
- clinical triad: 1) palpable purpura, 2) abdominal pain, 3) arthritis
- skin: palpable, non-thrombocytopenic purpura in lower extremities and buttocks, edema, scrotal swelling
- joints: arthritis/arthralgia involving large joints associated with painful edema
- GI: abdominal pain, GI bleeding, intussusception
- renal: microscopic hematuria, IgA nephropathy, proteinuria, HTN, renal failure in <5%

Investigations
- no routine investigations performed – diagnosis is mainly based on clinical features
- urinalysis (blood, protein creatinine ratio), serum (urea/electrolytes, creatinine, albumin, elevated IgA)
- skin/renal biopsy – IgA deposition
- ultrasound – intussusception/perforation, testicular pain/swelling
- rule out other autoimmune conditions/vasculitides

Management
- mainly supportive (e.g. elevation for edema)
- anti-inflammatory medications for joint pain, corticosteroids for select patients
- monitor for protein on urinalysis and hypertension every month for 6 mo to check for renal disease, which may develop late (immunosuppressive therapy if severe)

Prognosis
- self-limited, resolves within 4 wk
- recurrence in about one-third of patients
- long-term prognosis dependent on severity of nephritis

KAWASAKI DISEASE
- acute vasculitis of unknown etiology (likely triggered by infection)
- medium-sized vasculitis with predilection for coronary arteries
- most common cause of acquired heart disease in children in developed countries
- peak age: 3 mo-5 yr; Asian people>Black people>White people

Kawasaki Diagnostic Criteria

Warm CREAM
Warm: >5 d fever
Conjunctival injection
Rash
Edema of hands and feet
Adenopathy
Mucosal changes

Diagnostic Criteria
- fever persisting ≥5 d AND ≥4 of the following features
  1. bilateral, non-exudative conjunctival injection
  2. oral mucous membrane changes (fissured lips, strawberry tongue, injected pharynx)
  3. changes of the peripheral extremities
     - acute phase: extremity changes including edema of hands and feet or erythema of palms or soles
     - subacute phase: periungual desquamation

4. polymorphous rash
5. cervical lymphadenopathy >1.5 cm in diameter (usually unilateral)

- exclusion of other diseases (e.g. scarlet fever, measles)
- incomplete Kawasaki disease: fever persisting ≥5 d and 2-3 of the above criteria
  - further evaluation dictated by CRP, ESR, and supplemental laboratory criteria

Management

- initial therapy: IVIg (2 g/kg) and high dose of ASA (30-50 mg/kg/d, max 4 g/d)
- once afebrile >48 h: low dose of ASA (3-5 mg/kg/d) until platelets normalize, or longer if coronary artery involvement (usually a minimum of 6 wk)
- IVIg within 10 d of fever onset reduces risk of coronary aneurysm formation
- if fever persists 24-36 h after IVIg, repeat IVIg treatment at the same dose; if second dose fails, trial a third IVIg treatment or IV pulse methylprednisolone
- baseline 2D-echo and follow-up periodic 2D-echo (usually at 2, 6 wk)

Complications

- coronary artery vasculitis with aneurysm formation occurs in 20-25% of untreated children, <5% if receive IVIg within 10 d of fever
- 50% of aneurysms regress within 2 yr
- anticoagulation for multiple or large coronary aneurysms

Common Medications

Table 49. Commonly Used Medications in Paediatrics

Drug Name	Dosing Schedule	Indications	Comments
acetaminophen	10-15 mg/kg/dose PO q4-6 h PRN	Analgesic, antipyretic	Not to exceed 60 mg/kg/d in neonates or 75 mg/kg/d in older children to a max of 4 g/d Causes hepatotoxicity at high doses
amoxicillin	80-90 mg/kg/d PO divided q8h	Otitis media	
dexamethasone	0.6 mg/kg PO x1 0.6 mg/kg/d PO for 2 d	Croup Acute asthma	
fluticasone (Flovent®)	Moderate dose – 250-500 µg/d divided BID High dose – >500 µg/d divided BID		
ibuprofen	5-10 mg/kg/dose PO q6-8 h	Analgesic, antipyretic	Use cautiously in patients with liver impairment, history of GI bleeding or ulcers
iron	6 mg/kg/d elemental iron PO once daily or divided TID	Anemia	Side effects: dark stool, constipation, dark urine
polyethylene glycol 3350 (PEG)	Disimpaction: 1-1.5 g/kg/d x3 d Maintenance: starting dose at 0.4-1 g/kg		
prednisone/prednisolone	1-2 mg/kg/d PO x5 d 3-4 mg/kg/d PO then taper to 1-2 mg/kg/d PO once platelet count >30 x 109/L 60 mg/m^2/d PO	Asthma ITP Nephrotic syndrome	Oral prednisone is bitter tasting, consider using prednisolone
salbutamol (Ventolin®)	0.01-0.03 mL/kg/dose in 3 mL NS via nebulizer q0.5-4h PRN 100-200 µg/dose prn, max 4-8 puffs frequency q4 h	Acute asthma Maintenance treatment for asthma	Can cause tachycardia, hypokalemia, restlessness

Landmark Paediatric Trials

Trial Name	Reference	Clinical Trial Details
NUTRITION		
LEAP	NEJM 2015;372(9):803-813	Prevalence of peanut allergy at 60 months of age was significantly reduced in the consumption group, regardless of whether the infant had an initially positive skin-prick test. Increased levels of peanut-specific IgG4 antibody was prevalent in the consumption group. Raised titres of peanut-specific IgE antibody were prevalent in the avoidance group.
DIABETES		
TODAY	NEJM 2012;366(24):2247	699 patients participated. Failure rates were 51.7% for metformin alone, 38.6% for metformin plus rosiglitazone, and 46.6% for metformin plus lifestyle intervention. Metformin plus rosiglitazone was significantly better than metformin alone. Metformin plus lifestyle intervention was not significantly different from metformin alone or metformin plus rosiglitazone.
ELLIPSE	NEJM 2019;381(7):637	After 26 weeks, youth in the liraglutide plus placebo group had a mean glycated hemoglobin level decrease by 0.64 percentage points, while youth in the placebo plus metformin group saw an increase of 0.42 percentage points. Youth taking liraglutide reported increased overall adverse events and gastrointestinal adverse events.

PM Palliative Medicine

Brian Hyung and **Jack Su,** chapter editors
Ming Li and **Jacqueline van Warmerdam,** associate editors
Vrati Mehra and **Sarah House,** EBM editors
Dr. Risa Bordman, Dr. Adam Rapoport, and **Dr. Donna Spaner,** staff editors

Acronyms

ADLs	activities of daily living	CPR	cardiopulmonary resuscitation	EOL	end-of-life
AND	allow natural death	DNR	do not resuscitate	SDM	substitute decision maker

Palliative Approach to Care

Palliative Care

Definition

- an approach that seeks to improve the quality of life of patients and their families, facing a life-threatening illness through the prevention and relief of suffering
- applicable at any time during a life-limiting illness, and may be delivered in conjunction with life-prolonging or curative intervention
- palliative approach to care is not just for EOL

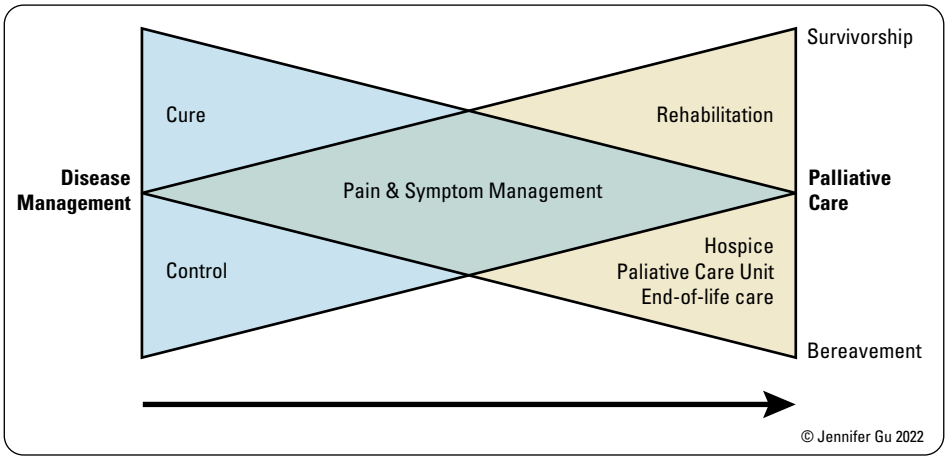

Figure 1. Palliative care enhanced model
Courtesy Dr. Philippa Hawley

Palliative Care Assessment

- comprehensive and includes physical, psychosocial, and spiritual domains of care
- complete medical history – includes determining patient's knowledge of their illness and their goals of care
- physical symptom assessment – patient's opinion of severity is the gold standard, and may be measured using assessment tools such as the Edmonton Symptom Assessment System (ESAS)
- functional status assessment – ability to perform ADLs, measured using tools such as the Palliative Performance Scale (PPS)
- psychosocial symptom assessment – anxiety, depression, family/caregiver distress, and cultural and financial status
- spiritual assessment – religious beliefs, coping mechanisms, and distress
- medication review – limit polypharmacy

See Landmark Palliative Care Trials table for more information on the study by Temel et al., 2010 which details the benefits of early palliative care for patients with metastatic Non–Small-Cell Lung Cancer.

See Landmark Palliative Care Trials table for more information on the ENABLE II trial, which details the effect of a nursing-led intervention on quality of life (QoL), symptom intensity, mood, and resource use in patients with advanced gastrointestinal tract, lung, genitourinary tract, or breast cancer.

See Landmark Palliative Care Trials table for more information on study by Back et al., 2007 which details the efficacy of communication skills training for giving bad news and discussing transitions to palliative care.

Pain and Symptom Management

Assessment Tools

- **Edmonton Symptom Assessment System (ESAS):** a tool used to screen for common symptoms seen in palliative care. Patients/caregivers are asked to rate the intensity of symptoms from 0 to 10 on a numeric rating scale where 0 represents the absence of the symptom and 10 represents the worst severity of the symptom. Assesses: pain, tiredness, nausea, depression, anxiety, drowsiness, appetite, well-being, shortness of breath, and "other problems" associated with specific conditions such as pruritus in liver disease and cough in lung disease. The ESAS gives a measure of symptom burden and allows for tracking of the efficacy of interventions over time

Patient's Name _____

Date _____ Time _____ AM / PM

On a scale of 0 to 10 please circle the number that best applies each of the following. (0 = best or none and 10 = worst)

No pain	1	2	3	4	5	6	7	8	9	10	Worst possible pain
Not tired	1	2	3	4	5	6	7	8	9	10	Worst possible tiredness
No nauseated	1	2	3	4	5	6	7	8	9	10	Worst possible nausea
Not depressed	1	2	3	4	5	6	7	8	9	10	Worst possible depression
Not anxious	1	2	3	4	5	6	7	8	9	10	Worst possible anxiety
Not drowsy	1	2	3	4	5	6	7	8	9	10	Worst possible drowsiness
Best appetite	1	2	3	4	5	6	7	8	9	10	Worst possible appetite
Best feeling of wellbeing	1	2	3	4	5	6	7	8	9	10	Worst possible feeling of wellbeing
No shortness of breath	1	2	3	4	5	6	7	8	9	10	Worst possible shortness of breath
Other problem	1	2	3	4	5	6	7	8	9	10	

Completed by (please check one): Patient ☐ Caregiver ☐ Caregiver assisted ☐

Figure 2. Edmonton Symptom Assessment System (ESAS)
Adapted from: Hui D, Bruera D, The Edmonton Symptom Assessment System 25 Years Later: Past, Present, and Future Developments, J Pain Symptom Manage 53(3):632

- **Palliative Performance Scale (PPS):** a tool used to assess functional status. Assesses 5 components: ambulation, activity and evidence of disease, self-care, intake, and consciousness level. Has prognostic value in patients with advanced cancer

Table 1. Palliative Performance Scale

PPS Level	Ambulation	Activity and Evidence of Disease	Self-Care	Intake	Conscious Level
100%	Full	Normal activity and work No evidence of disease	Full	Normal	Full
90%	Full	Normal activity and work Some evidence of disease	Full	Normal	Full
80%	Full	Normal activity with effort Some evidence of disease	Full	Normal or reduced	Full
70%	Reduced	Unable to do normal job/work Significant disease	Full	Normal or reduced	Full
60%	Reduced	Unable to do hobby/housework Significant disease	Occasional assistance necessary	Normal or reduced	Full or confusion
50%	Mainly sit/lie	Unable to do any work Extensive disease	Occasional assistance necessary	Normal or reduced	Full or confusion
40%	Mainly in bed	Unable to do most activities Extensive disease	Mainly assisted	Normal or reduced	Full or drowsy ± confusion
30%	Totally bed bound	Unable to do any activities Extensive disease	Total care	Normal or reduced	Full or drowsy ± confusion

Adapted from: Medical care of the dying, 4th ed. Victoria: Victoria Hospice Society, 2006. Version 2

Table 1. Palliative Performance Scale

PPS Level	Ambulation	Activity and Evidence of Disease	Self-Care	Intake	Conscious Level
20%	Totally bed bound	Unable to do any activities Extensive disease	Total care	Minimal to sips	Full or drowsy ± confusion
10%	Totally bed bound	Unable to do any activities Extensive disease	Total care	Mouth care only	Drowsy or coma ± confusion
0%	Death	—	—	—	—

Adapted from: Medical care of the dying, 4th ed. Victoria: Victoria Hospice Society, 2006. Version 2

Table 2. Symptom Management

Symptom	Non-Pharmacologic Management	Pharmacologic Management
Constipation	Rule out obstruction, impaction, anorectal disease, and spinal cord pathology Hydration, orally where possible Increase mobility	Stimulant laxatives (senna), osmotic laxatives (lactulose) Titrate to bowel movement at least q3 d
Dyspnea	Elevate head of bed, eliminate allergens, and open window/use fan	Oxygen, bronchodilators, opioids (e.g. morphine, hydromorphone)
Hiccups	Swallow 1 tsp of dry sugar, or dry bread (nasopharyngeal stimulation/vagus nerve stimulation) Rebreathing into paper bag (increases partial pressure of CO_2)	Dopamine antagonists (e.g. chlorpromazine, haloperidol, metoclopramide) Smooth muscle relaxants (e.g. hyoscine butylbromide (Buscopan®), baclofen)
Nausea and Vomiting	Frequent and small meals, avoid offensive strong odours, and treat constipation if present	Raised ICP: dexamethasone Anticipatory nausea, anxiety: lorazepam Vestibular disease, vertigo: dimenhydrinate Drug induced, hepatic, or renal failure: prochlorperazine, haloperidol Gastroesophageal reflux disease: proton pump inhibitor (PPI), H2 antagonist Gastric stasis: metoclopramide Bowel obstruction: metoclopramide, dexamethasone, octreotide
Pain	Hot and cold compresses, art/music therapy, relaxation techniques, physical therapy, massage therapy, acupuncture, and cognitive behavioural therapy (CBT)	Nociceptive pain: non-opioids (NSAIDs, acetaminophen), weak opioids (codeine, tramadol), strong opioids (e.g. morphine, hydromorphone, oxycodone, fentanyl) Neuropathic pain: anticonvulsants (gabapentin, pregabalin), antidepressants (tricyclic antidepressants (TCAs)), selective serotonin reuptake inhibitors (SSRIs), steroids (dexamethasone) Bony pain: NSAIDs, acetaminophen and/or opioids, depending on pain severity; bisphosphonates, radiation therapy For more information on pain management, see Anesthesia, A25
Pruritus	Bathe with tepid water, and avoid soap and bath oils	Antihistamines, phenothiazines, topical low potency corticosteroids, calamine lotion
Fatigue	Modify environment and activities to decrease energy expenditure Optimize fluid and electrolyte intake Educate and support patient and family Exercise	Treat underlying condition(s) if present, (eg. methylphenidate, dexamethasone)
Psychiatric	CBT, support groups, art/music therapy	Agitation: neuroleptics Confusion/Delirium: treat underlying etiology if possible. Otherwise manage with neuroleptics (e.g. haloperidol) Depression: standard SSRIs, serotonin and norepinephrine reuptake inhibitors (SNRIs) may be too slow depending on patient prognosis, may consider psychostimulants (e.g. methylphenidate, ketamine)
Oropharyngeal Secretions (Death Rattle)	Reassure family that patient is not in respiratory distress Oral suctioning, avoid deep suctioning Discontinue unnecessary IV solutions Re-positioning (on side, elevated) Monitor for adverse effects (xerostomia, delirium, sedation)	Anticholinergic agents used to dry secretions Hyoscine hydrobromide (scopolamine) SC or transdermal, glycopyrronium (glycopyrrolate) SC

Care of the Dying Patient

General Predictors of Decline in the Final Months of Life

- decreasing activity – functional performance status declining, limited self-care, in bed or chair 50% of day, and increasing dependence in most ADLs
- co-morbidity – biggest predictive indicator of mortality and morbidity
- general physical decline and increasing need for support
- advanced disease – unstable, deteriorating complex symptom burden
- decreasing response to treatments, decreasing reversibility
- choice of no further active treatment
- progressive weight loss (>10%) in the past six months
- repeated unplanned/crisis admissions
- sentinel event (e.g. serious fall, bereavement, transfer to nursing home)
- serum albumin <25 g/L
- considered eligible for terminal illness disability benefits

Changes in Last Hours of Life

- decreased level of consciousness
- changes in breathing pattern (Cheyne-Stokes breathing)
- airway secretions causing noisy breathing
- inability to swallow safely and increased risk of aspiration
- delirium (terminal restlessness)
- mottling of the hands, feet, and legs
- cool extremities

Care of the Patient in the Final Days of Life

- educate the family on the physiological changes in the dying process and discuss potentially difficult decisions (e.g. hydration)
- have a plan in place for an expected death in the home (EDITH), who to call (not 911), and how the death certificate will be made available to the funeral home
- if patient is unable to swallow, administer essential medications by non-oral routes (e.g. subcutaneous, gastrostomy tube, intravenous, nasal and oral transmucosal, rectal, transdermal), with subcutaneous being the preferred option
- discontinue non-essential and potentially inappropriate medications (e.g. for primary and secondary prevention); review other measures such as IV/SC hydration and consider stopping if no longer beneficial

Psychosocial and Spiritual Needs

- palliative care assessment includes addressing psychosocial and spiritual well-being
- psychosocial needs pertain to the psychological and emotional well-being of patients and their carers, including concerns such as self-esteem, adaptation to illness, communication, and social functioning
- patient's psychosocial experience is further shaped by the experience of pain and other symptoms related to the condition and its treatment
- spiritual needs pertain to the manner in which the patient expresses meaning, value, and purpose in life. May include, but is not limited to, religious practices or philosophical reflection

Approach to Assessing Psychosocial and Spiritual Needs

- holistic psychosocial assessment can help identify supports a person might need during their illness. Psychosocial issues can manifest as physical symptoms (e.g. pain, constipation, nausea). Therefore, it is important to be aware of physiological symptoms that may indicate depression and anxiety
- mental and emotional needs – fear, worry, insomnia, panic, anxiety, nervousness, or lack of energy
- social needs – family dynamics, communication, social and cultural networks, perceived social support, finances, intimacy, living arrangements, caregiver availability, etc.
- cultural needs – beliefs and preferences, linguistic needs, health behaviours, traditions, rituals, and cultural barriers to accessing health
- to further explore questions about spirituality, the FICA spiritual assessment tool may be used
- **FICA** – the four components to cover during a spiritual care assessment are: Faith or beliefs, Importance of those beliefs, patient's participation in a religious or spiritual Community, and how healthcare providers should Address the patient's healthcare issues

Interprofessional Care Plan for Psychosocial and Spiritual Needs

- interprofessional team of care providers including physicians, nurse practitioners, nurses, social workers, psychologists, chaplains, spiritual advisors, pharmacists, and physical and occupational therapists assist in the following interventions:
  - home care, respite care, social networks and activities, problem-solving and education, one-on-one therapy, and group work

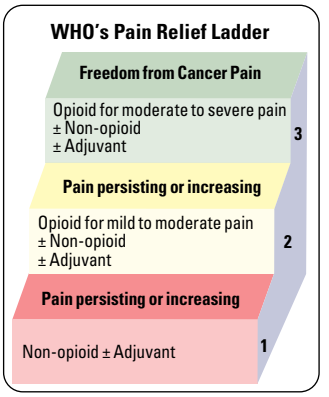

Figure 3. WHO's Pain Relief ladder
WHO's Pain Relief Ladder, available from: https://www.who.int/cancer/palliative/painladder/en/"

5 Dimensions of a Good Death
Quality End-Of-Life Care: Patients' Perspectives JAMA 1999;281:163-168

- Pain/symptom management
- Avoiding prolongation of dying
- Achieving a sense of control
- Relieving burden on others
- Strengthening relationships with loved ones

See Landmark Palliative Care Trials table for more information on the study by Naylor et al., 1999, which details the effectiveness of advanced practice nurse-centered discharge planning and home follow-up intervention for older aged individuals at risk for hospital readmissions.

See Landmark Palliative Care Trials table for more information on study by Christakis et al., 2000, which details doctors' prognostic accuracy in terminally ill patients and to evaluate the determinants of that accuracy.

End-of-Life Decision Making

Types of Discussions

Advance Care Planning Discussion
- it involves a mentally capable patient:
  1. identifying their substitute decision maker (SDM) by preparing a Power of Attorney. If no Power of Attorney is chosen, then the SDM hierarchy list in the Health Care Consent Act applies
  2. a discussion about one's values, beliefs, and wishes for future health care, should one become incapable of making health care decisions

Goals of Care Discussion
exploratory discussion where the health care provider and patient discuss the patient's current medical issues, their understanding of their illness, and possible treatments and outcomes. May or may not include discussion about code status.

Code Status Discussion
- discussion with patient about level of intervention they would want in the event of cardiac or respiratory arrest
  - **full code** - patient would like to receive CPR, defibrillation, and life support
  - **Do Not Resuscitate (DNR)** - patient would not like to receive CPR or life support, only active medical management
  - comfort measures - patient would not like to receive CPR, life support, or active medical management
  - **Allow Natural Death (AND)** - alternative term to DNR. Often a gentler term to help with the discussion

- CPR is rarely effective in the patient with advanced incurable illness
- DNR order is almost always consistent with palliative goals of care

When to Initiate EOL Care Discussions
- recent hospitalization for serious illness, or during a transition in care
- severe progressive medical condition(s)
- death expected within 6-12 mo
- patient rewritten will and/or spiritual wishes
- if the patient requests medical assistance in dying (MAID)

Power of Attorney for Personal Care
- see Ethical, Legal, and Organizational Medicine, ELOM14

Communication

- strong communication is critical in all forms of medicine. This is especially true in palliative care, where difficult decisions must be made regarding goals of care, EOL care, and disclosure of information
- be cognizant of how a patient's (and their family's) beliefs, values, and spirituality may impact their decision making and/or their emotional response during palliative care conversations
- use both verbal and non-verbal means of communicating empathy and caring to build rapport, and help de-escalate the intense emotions the patients may experience including anger, grief, and feeling overwhelmed

Approach to Communicating Bad News

SPIKES
S – Setting up the interview: create privacy by bringing the patient to a quiet comfortable environment. Ensure you have enough time to have an extended conversation with the patient. Ask them if they wish for family members or other supports to be present
P – assess Perception: what does the patient and/or their family understand about their illness at present? Use open-ended questions and fill any major gaps to ensure mutual understanding
I – Invitation: how does the patient wish to hear the information? How much details do they want? Do they want to first understand the process that led the care team to their diagnosis/prognosis/treatment decision, or do they just want to hear the news upfront?
K – Knowledge sharing: provide the information based on the preferences expressed in the "invitation" section in small segments using non-technical terms
E – Emotions: respond to the patient's/family's emotions. Allow them time to process the information. Silence is okay. Offer to answer any questions they may have, but also recognize that some patients may wish to discuss further details at a later time
S – Strategy and Summary: if the patient and their family are comfortable, summarize the conversation and discuss next steps

Estimating Life Expectancy
- when asked about prognosis, be wary of being overly specific
- use time frames such as hours to days, days to weeks, weeks to many weeks, or months
- clinicians consistently overestimate survival when prognosticating

Collaboration

Interprofessional Team
- interprofessional team may include the following members:
  - physicians: may be primary care providers, or have specialty training in palliative care; they provide medical management and symptom relief
  - nurses: provide patient education in addition to clinical nursing; often with advanced practices in setting of hospice or home care
  - social workers/case managers: facilitate advance care planning conversations and other psychosocial interventions for patients and their families
  - pharmacists: timely provision of medications, assessment of medication plans
  - occupational therapists: identify important life roles and activities to patients, and address barriers to performing these activities
  - physiotherapists: optimize patient comfort by maintaining physical function during disease progression
  - dieticians: optimize a nutritional plan focused on the patient's needs and wishes
  - spiritual care workers: provide spiritual and religious care for persons with life-limiting disease
- all members of the palliative care team provide assessment of palliative care needs through the use of validated tools such as the ESAS and the PPS
- palliative care team collaborates through ongoing care conversations with the patient and their family to discuss patient's condition, course of illness, treatment options, goals, and plan of care

Suffering

Definition
- a multidimensional experience of severe distress that diminishes an individual's ability to find peace in their present situation, with contributions from physical symptoms, psychological distress, existential concerns, and social-relational worries

Key Points
- suffering can occur at any moment within the palliative context
- suffering is subjective and unique to the patient
- anguish and despair are justifiable responses to difficult human situations
- patients may suffer not only from illness, but also from treatments
- suffering is not confined to physical symptoms
- it is impossible to anticipate the source of another's suffering

Sources of Suffering
- **physical concerns**
  - impaired activities
  - loss of physical independence
  - symptoms (e.g. pain, tiredness, poor sleep, loss of appetite)
- **social-relational concerns**
  - family distress or dysfunction
  - burden on others
- **psychological concerns**
  - fear or dread of the unknown
  - loss of balance and control
  - difficulty accepting the situation
  - overwhelmed by life circumstances
  - comorbid depression and anxiety
- **spiritual concerns**
  - unfulfilled needs of love, virtue, faith, and/or hope
  - questioning meaning of life or death
  - anger towards a higher being (as defined by the individual)
  - viewing illness as punishment
- **existential concerns**
  - loss of dignity
  - desire for death
  - loss of will to live

Options to Relieve Refractory Suffering

- **palliative sedation therapy**: the use of pharmacological agents to reduce consciousness. Only considered in patients who have been diagnosed with advanced progressive illnesses and reserved for treatment of intolerable and refractory symptoms
- **medical assistance in dying (MAID):** in Canada, a specific process that occurs when a mentally competent patient makes a written request to end one's life. The patient is interviewed by 2 different clinicians, one of which is the MAID provider. A physician or nurse practitioner administers medications that cause a person's death or the patient is prescribed medications to self-administer that will cause one's own death. Note: who is eligible and the ability to consent in advance is still an ongoing federal government process

https://www.justice.gc.ca/eng/cj-jp/ad-am/bk-di.html

Types of Grief

- **anticipatory grief** – feelings of grief occurring before an impending loss, including being concerned for the dying person, balancing conflicting demands, and preparing for death
- **acute grief** – immediate reaction to the death of a loved one. In the majority of cases, support from family and friends over time will help the bereaved accept the loss
- **complicated grief** – unanticipated progression of grief, which severely interferes with a person's ability to function. Characterized by prolonged duration, maladaptive thoughts, dysregulated emotions, and dysfunctional behaviours; depression and anxiety may be prevalent

Self-Care

Definition

- proactive, holistic pursuit of personal well-being in tandem with professional responsibility for patient wellbeing

Benefits

- balances compassion for oneself and compassion for others
- translates improvements in professionals' quality of life to improvements in patients' care
  - positively predicts competence in coping with death and achieving compassion satisfaction
  - negatively predicts risk of fatigue and burnout
- requires and cultivates self-awareness, i.e. the culmination of knowledge of and empathy for oneself
- promotes sustainable resilience through the development of coping skills, the balance between professional demands and personal needs, and the commitment to overall well-being

Strategies

- within the workplace: individual regulation of workload demands and establishment of boundaries, opportunity for team bonding/debriefing, promotion of resources/supports that can attend to professionals' needs, and development of a culture supportive of and conducive to self-care
- beyond the workplace: a range of health-promoting behaviours (e.g. balanced diet, sleep hygiene, exercise, meditation, interpersonal fulfilment, spiritual practice)

Paediatric Palliative Care

Unique Considerations for Paediatric Patients

- the unit of care in paediatric palliative care is always the family, and the afflicted child. This includes siblings, who are often affected in various ways
- ideally should be offered early after diagnosing a potential life-limiting or life-threatening disease and continued through the course of treatment, along with standard/curative care
- respite services for families is a key aspect of palliative care for medically complex and technology-dependent children
- bereavement support to parents and siblings after the death of a child is a standard offering
  - emotional maturity and cognitive abilities vary between children and adults, and are determined by the developmental level of the child rather than their chronological age
  - unique pediatric life-threatening illnesses
  - emotional and psychological issues differ for children
  - unique challenge of dealing with the child, parents, and siblings
  - decision-making authority, even in matters related to end of life, depends on the young person's capacity. However, many decisions are family-centred, and made with the pediatric patient and the parents together

Predominant Pediatric Conditions Receiving Palliative Care:
1. Genetic/congenital disease (40.8%)
2. Neuromuscular disease (39.2%)
3. Cancer (19.8%)
4. Respiratory disease (12.8%)
5. Gastrointestinal disease (10.7%)

Table 3. Categories of Paediatric Patients Who May Benefit From Palliative Care

Category 1	**Life-threatening conditions for which curative treatment may be feasible but can fail** Palliative care is involved when treatment fails or during acute crisis Palliative care is no longer required upon achieving long-term remission or successful treatment e.g. cancer, irreversible organ failure
Category 2	**Conditions in which premature death is inevitable** Intensive treatment over a long period of time to prolong life and allow normal activities e.g. cystic fibrosis, Duchenne muscular dystrophy
Category 3	**Progressive conditions without curative treatment options** Treatment is exclusively palliative and can extend over many years e.g. Batten disease
Category 4	**Irreversible but non-progressive conditions causing severe disability** e.g. severe cerebral palsy, multiple disabilities after brain or spinal cord injury

Source: A guide to children's palliative care: supporting babies, children and young people with life-limiting and life-threatening conditions and their families. Together for Short Lives 2018

Assessment Tools

Symptom Screening in Paediatrics Tool (SSPedi)
- used in children age 8-18 yr to assess symptoms over time and the efficacy of interventions
- symptoms rated on a five-point descriptive Likert scale
- assesses depression, anxiety, irritability, memory/cognition, changes in appearance, fatigue, mouth sores, headache, pain, tingling/numbness of extremities, N/V, appetite, changes in taste, constipation, and diarrhea

Mini-SSPedi
- a revised SSPedi geared towards children 4-7 y/o
- assesses the same 15 symptoms
- uses a three-point, face-based Likert scale
- keep in mind the child's stage of development when interpreting these tools
  - children 4-5 y/o old can describe concrete aspects of their own health
  - introspection develops around ages 6-8 y/o

Memorial Symptom Assessment Scale (MSAS)
- used in children 7+ y/o
- measures frequency, severity, and distress associated with 32 common physical and psychological symptoms
- uses a five-point Likert scale
- used in both clinical and research settings

Symptom Management

- children are often aware of their condition, and open communication with the child in regard to diagnosis and prognosis is encouraged to reduce anxiety and fear
  - child's stage of development and cognitive abilities should be considered when discussing concepts of illness, treatment decisions, EOL, and dying
- symptoms encountered near EOL, and their respective management are similar to that in adult care (see Table 1, PM3). However, the following are unique in paediatric management:
  - shared decision making involving the child (to the extent possible or desired), the parents, and the healthcare providers typically guides treatment and EOL care
  - symptom management may be over the course of years and therefore may require a transition plan into adult palliative services
  - play therapy and unstructured play reduces anxiety, depression, and aggression
  - creating a sense of normality in the child's life aids in emotional wellbeing (e.g. seeing friends, attending school, parental discipline)
  - the patient's pain and anxiety often correlate with parental anxiety and quality of life, and therefore managing these symptoms benefits the family unit
  - siblings should also be offered psychological supports

Landmark Palliative Medicine Trials

Trial Name	Reference	Clinical Trial Details
PALLIATIVE APPROACH TO CARE		
Temel et al., 2010	NEJM 2010; 363:733-742	**Title**: Early Palliative Care for Patients with Metastatic Non-Small-Cell Lung Cancer **Purpose**: To examine the effect of introducing early palliative care after diagnosis of metastatic non–small-cell lung cancer on patient-reported outcomes and end-of-life care. **Methods**: Patients (n= 322) were randomized to receive either an early nurse-led palliative care intervention addressing physical and psychosocial needs in addition to usual oncologic care v.s. routine oncology care. Primary outcomes included QoL, symptom intensity, and mood. **Results**: Of 151 randomized patients, 27 passed away, and 107 (86% of the remaining patients) completed assessments. Patients assigned to early palliative care had a better QoL, lower depressive symptoms, and longer median survival v.s. standard care (11.6 mo v.s. 8.9 mo, P=0.02). **Conclusions**: Early palliative care led to significant improvements in both QoL and mood among patients. Despite lesser aggressive EOL care, the intervention group had longer survival.
ENABLE II	JAMA 2009;302:741–749	**Title**: Effects of a Palliative Care Intervention on Clinical Outcomes in Patients with Advanced Cancer: the Project ENABLE II Randomized Controlled Trial **Purpose**: To determine the effect of a nursing-led intervention on QoL, symptom intensity, mood, and use of resources in patients with advanced cancer. **Methods**: Patients were randomized to receive multi-component intervention v.s. usual care (n= 322). Intervention included telephone-based care by advanced palliative care trained nurses, who provide structured educational and problem-solving sessions, to encourage patient activation, self-management, and empowerment and follow-up at least monthly with every patient. Primary outcomes included QoL, symptom intensity, and mood. Intensity of service was measured using days in the hospital and number of ED visits. **Results**: Longitudinal intention-to-treat analyses for the total sample revealed higher quality of life, lower depressed mood, and a trend toward lower symptom intensity. Similar results were seen among patients who passed away, except there was no change in symptom intensity. No differences were noted in the number of days in the hospital, ICU, or ED visits. **Conclusions**: A nurse-led, palliative care-focused intervention addressing physical and psychosocial care along with oncology care improved scores for QoL and mood.
Back et al., 2007	JAMA Intern. Med. 2007; 167:453-460	**Title**: Efficacy of Communication Skills Training for Giving Bad News and Discussing Transitions to Palliative Care **Purpose**: To evaluate the efficacy of a residential communication skills workshop (Oncotalk) for medical oncology fellows in changing observable communication behaviours. **Methods**: A cohort of 115 medical oncology fellows took part in Oncotalk which emphasized skills practice in small groups. The primary outcomes included participant communication skills measured during standardized patient encounters before and after the workshop in giving bad news and discussing transitions to palliative care. Comparisons were made using each participant as his or her own control. **Results**: Post-workshop encounters showed that participants improved in bad news skills (P<0.001) and transition skills (P<0.001). **Conclusions**: Oncotalk was a successful teaching model for improving communication skills for postgraduate medical trainees.
PATIENT ASSESSMENT		
Naylor et al., 1999	JAMA 1999;281:613–620	**Title**: Comprehensive Discharge Planning and Home Follow-up of Hospitalized Elders: A Randomized Clinical Trial **Purpose**: To examine effectiveness of advanced practice nurse-centered discharge planning and home follow-up intervention for elders at risk for hospital readmissions. **Methods**: Patients aged >64 yr were randomized to receive comprehensive discharge planning and home follow-up v.s. routine discharge. Primary outcome was time to first readmission. **Results**: Intervention group had longer time to first readmission, fewer multiple readmissions, fewer hospital days per patient, and lower healthcare costs. Control group patients were more likely than intervention group patients to be readmitted at least once. No significant differences were noted in postdischarge acute care visits, functional status, depression, or patient satisfaction. **Conclusions**: Intervention demonstrated great potential in promoting positive outcomes for hospitalized elders at high risk for rehospitalization while reducing costs.
Christakis et al., 2000	BMJ 2000;320:469	**Title**: Extent and Determinants of Error in Doctors' Prognoses in Terminally Ill Patients: Prospective Cohort Study **Purpose**: To describe doctors' prognostic accuracy in terminally ill patients and to evaluate the determinants of that accuracy. **Methods**: Prospective cohort study involving 343 doctors who provided survival estimates for 468 terminally ill patients at the time of hospice referral. Main outcome measures were the estimated and actual survival of patients. **Results**: Median survival was 24 days. Only 20% (92/468) of predictions were accurate (within 33% of actual survival); 63% (295/468) were overly optimistic and 17% (81/468) were overly pessimistic. Overall, doctors overestimated survival by a factor of 5.3. **Conclusions**: Doctors are systematically optimistic in estimating prognosis for terminally ill patients. This phenomenon may adversely affect the quality of care given to patients near the EOL.

Acronyms

ABI	ankle-brachial index
ABG	arterial blood gas
AIN	anterior interosseous nerve
APL	abductor pollicis longus
ARDS	acute respiratory distress syndrome
ATLS	advanced trauma life support
BIA-ALCL	breast implant-associated anaplastic large cell lymphoma
BMR	basal metabolic rate
CK	creatine kinase
CMC	carpometacarpal
CO	carbon monoxide
D5W	5% dextrose in water
DIEP	deep inferior epigastric perforator
DIP	distal interphalangeal joint
ENT	ear, nose, throat
EOM	extraocular movement
EPB	extensor pollicis brevis
FDP	flexor digitorum profundus
FDS	flexor digitorum superficialis
FTSG	full thickness skin graft
GAS	group A β-hemolytic Streptococcus
GBS	group B Streptococcus
GnRH	gonadotropin-releasing hormone
ICP	intracranial pressure
IGAP	inferior gluteal artery perforator
IP	interphalangeal
IVIg	intravenous immunoglobulin
MAP	mean arterial pressure
MC	metacarpal
MCP	metacarpophalangeal joint
NAC	nipple-areola complex
NCS	nerve conduction studies
NPWT	negative pressure wound therapy
NS	normal saline
OM	otitis media
ORIF	open reduction internal fixation
OT	occupational therapy
PIP	proximal interphalangeal joint
PMN	polymorphonuclear
PT	physiotherapy
PVD	peripheral vascular disease
RA	rheumatoid arthritis
RL	Ringer's lactate
ROM	range of motion
SGAP	superior gluteal artery perforator
SIADH	syndrome of inappropriate antidiuretic hormone
SIEA	superficial inferior epigastric artery
SLP	speech-language pathology
SOF	superior orbital fissure
STSG	split thickness skin graft
TBSA	total body surface area
TMJ	temporomandibular joint
UCL	ulnar collateral ligament
UV	ultraviolet
VCA	vascularized composite allotransplantation

Skin Lesions and Masses

Differential Diagnosis of Skin Lesions/Masses

- for background information see Dermatology, D4 and D8
- for biopsy techniques, see *Skin Biopsy Types and Techniques*, PL7

Surgical Management of Malignant Skin Lesions

- surgical treatment for all malignant skin lesions involves total excision of the primary lesion
- for pathophysiology and diagnosis see Dermatology, D40
- excision margin of lesion depends on the type of lesion, the lesion diameter, and the lesion depth
- for decisions regarding reconstruction using flaps or skin grafts, see *Reconstruction*, PL12

Precursors of Malignant Lesions

Table 1. Precursors

Basal Cell Carcinoma	Squamous Cell Carcinoma	Malignant Melanoma
Nevus sebaceous of Jadassohn	Actinic keratosis	Lentigo maligna
	Bowen's disease	Giant congenital nevus
	Bowenoid papulosis	Dysplastic nevus
	Leukoplakia	
	Erythroplasia	

Surgical Margins

Table 2. Surgical Margins for Basal Cell Carcinoma

Type of Lesion	Surgical Margins
Low-Risk	>2-3 mm
High-Risk*	3-5 mm

*High-risk features include: diameter and location (>20 mm trunk, >6 mm face, hands, and feet), poorly defined borders, recurrent lesion, poor differentiation, and type of lesion (e.g. sclerosing basal cell carcinoma), determined via initial biopsy

Table 3. Surgical Margins for Squamous Cell Carcinoma

Type of Lesion	Surgical Margins
Low-Risk	>5 mm
High-Risk*	>10 mm

*High-risk features include: depth >2 mm, facial lesions, poorly defined borders, recurrent lesion, perineural invasion, poor differentiation, and type of lesion (e.g. morpheaform), determined via biopsy

Table 4. Surgical Margins for Malignant Melanoma

Depth of Lesion*	Surgical Margins
In situ	0.5 cm
<1 mm***	1 cm
1-1.99 mm***	1-2 cm
≥2 mm***	2 cm**

*Determined via excisional biopsy
**Or more as long as it doesn't interfere with reconstruction
***with or without ulceration

Basic Surgical Techniques

Sutures and Suturing

ANESTHESIA

- irrigate before injecting anesthetic, followed by debridement and more vigorous irrigation

Table 5. Toxic Limit and Duration of Action (1 cc of 1% solution contains 10 mg lidocaine)

	Without Epinephrine	With Epinephrine (vasoconstrictor, limits bleeding)
Lidocaine (Xylocaine®)*	5 mg/kg, lasts 45-60 min	7 mg/kg, lasts 2-6 h
Bupivicaine (Marcaine®)	2 mg/kg, lasts 2-4 h	3 mg/kg, lasts 3-7 h

* Lidocaine toxicity symptoms include: circumoral numbness, light-headedness, and drowsiness followed by tremors and seizures. Cardiac and respiratory signs are late findings

- e.g. when using 1% lidocaine without epinephrine in a 70 kg patient:
  - 1% = 1g/100 cc = 1000 mg/100 cc = 10 mg/cc
  - toxic limit = 5 mg/kg x 70 kg = 350 mg
  - max bolus injection = 350 mg ÷ 10 mg/cc = 35 cc (may add more after 30 min)

Traumatic tattoos are permanent discolourations resulting from new skin growth over foreign material or dirt left behind in the dermis. Copious irrigation and debridement should be done ASAP in order to prevent traumatic tattoos, as they are very difficult to treat later

IRRIGATION AND DEBRIDEMENT

- irrigate copiously with a physiologic solution such as RL or NS to remove surface clots, foreign material, and bacteria
- debride all obviously devitalized tissue; irregular or jagged wounds must be excised to produce sharp wound edges that will assist healing when approximated
- wounds left unapproximated ≥8 h should be debrided and copiously irrigated to ensure wound edges are optimized for healing
- there is high-risk of infection for any wound closed primarily after 8 h

SUTURES

- use of a particular suture material is dependent on surgeon preference; however, skin should be closed with a non-absorbable, monofilament suture material when traumatic mechanisms are involved to prevent harboring bacteria in suture material

Table 6. Suture Materials: Absorbable vs. Non-absorbable and Monofilament vs. Multifilament

Suture Materials	Uses	Examples	Notes
Absorbable	Deep sutures under short-term tension Skin closure in children	Plain gut®, Vicryl®, Polysorb®, Biosyn®, Monocryl®, Caprosyn®, chromic gut, fast absorbing gut	Loses at least 50% of their strength in 4 wk; eventually absorbed
Non-Absorbable	Skin closure Sites of long-term tension	Nylon, polypropylene (Prolene®), stainless steel, silk, Ticron®, Ethibond®	Lower likelihood of wound dehiscence, more difficult to tie, makes track marks
Monofilament	Everyday use and optimal for contaminated and infected wounds (lower likelihood of bacterial trapping in suture material)	Monosof®, Monocryl®, Biosyn®, Prolene®	Slides through tissue with less friction; more memory/stiffness; more difficult to tie; requires multiple throws (lower knot security)
Multifilament	Used to close deep layers, such as in traumatic degloving injuries	Vicryl® and silk, Ticron®, Ethibond®	Less memory/stiffness, thus easier to work with (higher knot security); greater infection risk

BASIC SUTURING TECHNIQUES

Basic Suture Methods

- simple interrupted: can be used in almost all situations
- sub-cuticular: good cosmetic result but weak, used in combination with deep sutures; not used in trauma
- vertical / horizontal mattress: for areas difficult to evert (e.g. volar hand)

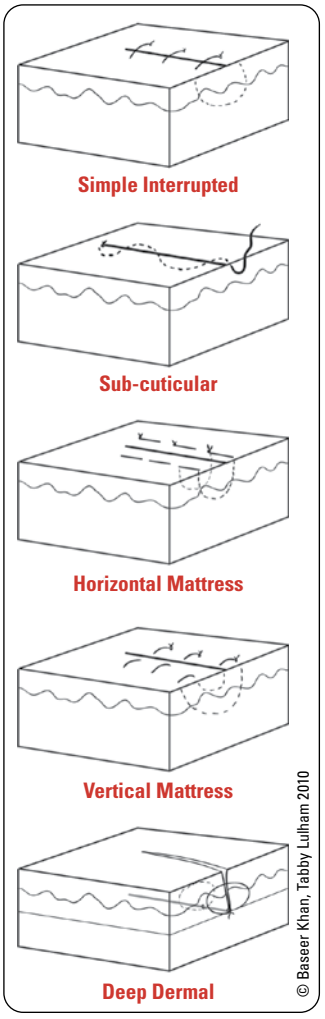

Figure 13. Basic suture methods

- continuous over and over (i.e. "running," "baseball stitch"): time-saving, good for hemostasis
- deep / buried dermal: simple interrupted sutures placed in dermal layer, reduces skin tension for improved healing and are the only sutures that close the wound

Other Skin Closure Materials

- tapes: may be indicated for superficial wounds and those with opposable edges; tape cannot be used on actively bleeding wounds; when placed across the incision, will prevent surface marks and can be used as the primary closing material or as additional reinforcement after primary surface sutures have been removed
- skin adhesives: e.g. 2-octyl cyanoacrylate (e.g. Dermabond®) works well on small areas without much tension or shearing; may cause irreversible tattooing
- staples: steel-titanium alloys that incite minimal tissue reaction (healing is comparable to wounds closed by suture)

Excision

- plan your incision along relaxed skin tension lines to minimize appearance of scar
- use elliptical incision to prevent standing cone deformity (heaped up skin at end of incision), so the length of the ellipse should be approximately 3x the width
- if needed, undermine skin edges (separate skin from underlying fascia to allow wound edge manipulation and decrease tension)
- use layered closure including deep dermal sutures (decreases tension)

Skin Biopsy Types and Techniques

SHAVE BIOPSY

- used for superficial lesions where sampling of the full thickness of the dermis is not necessary or practical
- most suitable lesions for shave biopsies are benign lesions either elevated above the skin or have pathology confined to the epidermis (e.g. seborrheic or actinic keratoses, skin tags, and warts)
- high-risk of recurrence with shave biopsy for any lesions, including actinic or seborrheic keratoses
- rapid, requires little training, and does not require sutures for closure (caution in patients on anticoagulant treatment)
- heals by secondary intent (moist dressings should be used)
- should not be used for pigmented lesions – an unsuspected melanoma cannot be properly staged if partially removed

NEEDLE BIOPSY

- 21 G for lymph node biopsy
- Trucut® needle biopsy for breast masses suspected for carcinoma
  - needle biopsy has fallen out of favour for lymph node biopsies; excisional biopsy is the preferred method in this circumstance

INCISIONAL BIOPSY

- can be a punch biopsy, or an ellipse within the lesion (normal tissue must be included in biopsy)
- gives pathologists a portion of the lesion and the border with normal skin
- punch biopsies involve the removal of a full thickness core of tissue to allow sampling of the epidermis, dermis, fat, and potentially muscle depending on the area; performed with a round, disposable circular cutting surface on a plastic handle ranging in diameter from 2-10 mm
- punch biopsy wounds can be closed with suture or left to heal by secondary intention

EXCISIONAL BIOPSY

- performed for lesions that require complete removal for diagnostic purposes
- performed for lesions that cannot be adequately punch biopsied due to depth of lesion below surface
- for small pigmented lesions and atypical moles; if concerned about melanoma, can do a narrow margin excision for diagnosis and treatment (depending on depth in the case of melanoma)
- best for small lesions that are easily removed and primarily closed
- requires the greatest amount of expertise and time
- always requires sutures for closure

TECHNIQUE

General

- all shave and punch biopsies performed in clinic are done using aseptic technique, but are not sterile
- sterile gloves are indicated for biopsies and excisions in all patients

Steps to Ensuring an Optimized Scar

- Incisions should be made along resting skin tension lines
- Attain close apposition of wound edges
- Minimize tension on skin by closing in layers
- Evert wound edges
- Use appropriately sized suture for skin closure (5-0 on face; 3-0, 4-0 elsewhere)
- Ensure equal width and depth of tissue on both sides
- Remove sutures within 5-7 d from the face, 10-14 d from scalp/torso/extremities

Relaxed Skin Tension Lines

Natural skin/wrinkle lines with minimal linear tension. Placing incisions parallel to resting skin tension lines minimizes widening/hypertrophy and helps to camouflage scars. Relaxed skin tension lines are usually parallel to any existing wrinkle lines and perpendicular to the orientation of underlying muscle fibres (perpendicular to lines of maximum extensibility)

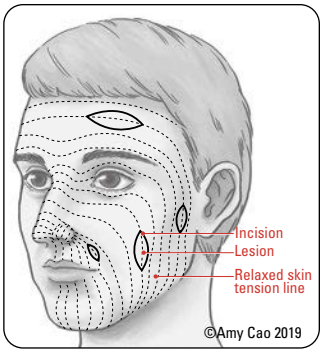

Figure 14. Incision of lesions along relaxed skin tension lines

Preparing the Site

- common skin antiseptics (Betadine®, chlorhexidine) can be used to prepare the biopsy site
- chlorhexidine is used in concentrations ranging from 0.5-4%. It is not typically used on the face, as it could get into the eyes or ears and may burn or cause damage. Most chlorhexidine preps also contain alcohol, which can be flammable, so allow to dry before the biopsy and certainly before using any cautery
- Betadine® (7.5% povidone–iodine) is safer for the head and neck (as to avoid the above problems with chlorhexidine) and around the eyes and ears. It is also used in "contaminated" areas such as the feet and groin
- mark the intended lesion and surgical margins with a surgical marker as the first step, since they may be temporarily obliterated following injection of the anesthetic
- for all biopsies, a sterile drape technique is indicated. Sterile towels are placed around the biopsy site after the area is cleansed and anesthetized

Anesthesia

- most commonly used local anesthetic is 1% or 2% lidocaine (with epinephrine)
- small amounts of epinephrine are added to constrict blood vessels, decrease bleeding, prolong anesthesia, and limit lidocaine toxicity. The local with epinephrine can be injected directly into the lesion
- local anesthetics with epinephrine may be used anywhere in the body, including the digits

Wounds

- wound: disruption of the normal anatomical relationships of tissue as a result of injury

Types of Wounds

- laceration: sharply cut tissue
- abrasion: superficial skin layer is removed, variable depth
- contusion: injury caused by forceful blow to the skin and soft tissue; entire outer layer of skin intact, yet injured
- avulsion: skin and soft tissue forcefully separated from deeper structures, potentially compromising blood supply or resulting in full detachment (amputation)
- puncture wounds: cutaneous opening relatively small as compared with depth (e.g. needle), including bite wounds
- crush injuries: caused by compression
- burns: thermal, chemical, electrical
- ulcers

Principles of Wound Healing

Table 7. Factors Influencing Wound Healing

Local	General
Mechanical (local trauma, significant crush, avulsion, tension)	Age (affects healing rate)
Blood supply (ischemia/circulation)	Nutrition
Technique and suture materials	Tobacco smoking
Retained foreign body	Alcohol consumption
Infection	Chronic illness (e.g. DM, cancer, dyslipidemia, renal failure, stroke)
Venous HTN	Immunosuppression (steroids, chemotherapy)
PVD	Tissue irradiation
Hematoma/seroma (↑ infection rate)	Genetic predisposition to abnormal healing (e.g. hypertrophic or keloid scarring, collagen vascular disease)
	Skin type

STAGES OF WOUND HEALING

- growth factors released by tissues play an important role
- scar is mature once it has completed the final stage, usually after 1-2 yr

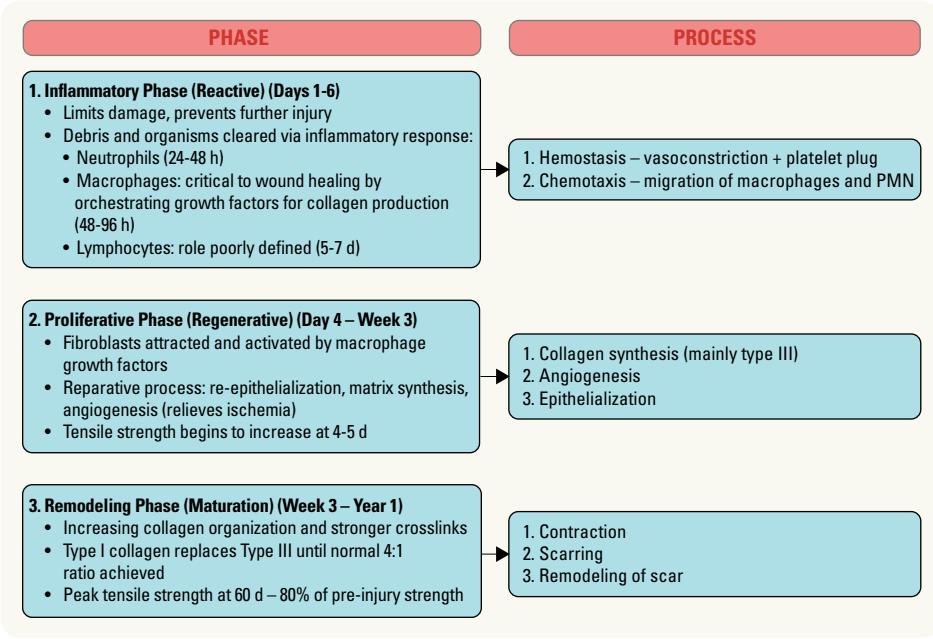

Figure 15. Stages of wound healing

TYPES OF WOUND HEALING

Primary (1°) Healing (First Intention)

- **definition**: wound closure by direct approximation of edges within hours of wound creation (i.e. with sutures, staples, skin graft, etc.)
- **indication**: recent (6-8 h, longer with facial wounds) wounds
- contraindications: animal/human bites, crush injuries, infection, long time lapse since injury (>6-8 h), retained foreign body

Secondary (2°) Healing/Spontaneous Healing (Second Intention)

- **definition**: wound left open to heal spontaneously (epithelialization occurs at 1 mm/d from wound margins in concentric pattern, contraction (myofibroblasts), and granulation)– maintained in inflammatory phase until wound closed; requires dressing changes
- **indication**: when 1° closure not possible or indicated (see *Primary Healing*)

Myofibroblasts are the cells responsible for wound contraction

Tertiary (3°) Healing/Delayed Primary Healing (Third Intention)

- **definition**: intentionally interrupt healing process (e.g. with packing, sharp debridement), then wound can be closed primarily at 4-10 d post-injury after granulation tissue has formed and there is <105 bacteria/g of tissue
- **indication**: contaminated (high bacterial count), long time lapse since initial injury, severe crush component with significant tissue devitalization, closure of fasciotomy wounds
- prolongation of inflammatory phase decreases bacterial count and lessens chance of infection after closure

ABNORMAL HEALING

Hypertrophic Scar

- **definition**: scar remains within boundaries of original scar
- red, raised, widened, frequently pruritic
- common sites: back, shoulder, sternum
- **treatment**: scar massage, pressure garments, silicone gel sheeting, corticosteroid injection, surgical excision if other options fail (however, may still recur)

Keloid Scar

- **definition**: scar grows outside boundaries of original scar
- red, raised, widened, frequently pruritic
- caused by:
  - genetic factors (highest rates in Black, and Asian individuals)
  - excess tension on wound or delayed closure (as in burn wounds)
- common sites: central chest, back, shoulders, deltoid, ear, angle of mandible
- **treatment**: multimodal therapy including: pressure garments, silicone gel sheeting, corticosteroid injection, fractional carbon dioxide ablative laser, surgical excision if radiation to be performed within the next 48 hours (however, this is typically very unsuccessful and there is often recurrence)

Spread Scar
- characterized by having exactly the same order of collagen fibres as normal scars
- clinically, a typical spread scar is flat, wide, and often depressed
- treatment: surgical excision and closure

Chronic Wound
- wound fails to achieve primary wound healing within 4-6 wk
- common chronic wounds include: diabetic, pressure, and venous stasis ulcers
- treatment: need to address underlying cause of chronicity (i.e. infection, ischemia, metabolic conditions, immunosuppression, radiation);
- Marjolin's ulcer: squamous cell carcinoma arising in a chronic wound secondary to genetic changes caused by chronic inflammation. All chronic wounds should be biopsied to rule out marjolin's ulcer

Infected Wounds

Definitions
- the presence of bacteria within a wound may be divided into 4 categories:
  - contamination: the presence of non-replicating microorganisms within a wound
  - colonization: the presence of replicating microorganisms within a wound
  - critical colonization: increasing bacterial burden; have delayed healing
  - infection: the presence of >105 microorganisms in a wound without intact epithelium or small amounts of a very virulent organism (e.g. GBS); have delayed healing and exhibit classic signs of infection
    - signs of infection: redness, swelling, pain, clinically unwell

Risk Factors for Infection
- Virulence of the infecting microorganism
- Amount of bacteria present
- Host resistance
- Immunocompromised host

Management of Acute Contaminated Wounds (<24 h)
- cleanse and irrigate open wound with at least 150 cc of physiologic solution (NS or RL) using sufficient pressure (4 to 15 PSI)
- evaluate for injury to underlying structures (vessels, nerves, tendons, and bone)
- control active bleeding, irrigation, and debridement
- debridement: removal of foreign material, devitalized tissue, and old blood (always take a swab if you suspect infection)
  - surgical debridement: blade and irrigation if indicated
- tetanus prophylaxis
- re-evaluate in 24-48 h to remove more dead tissue
  - if evidence of infection (i.e. erythema, warmth, pain, discharge), open infected portion of wound by removing sutures, swab sample for culture and sensitivity, irrigate wound, and allow healing by secondary intention via dressing use
  - risk factors for infection include: wound >8 h, severely contaminated, immunocompromised, involvement of deeper structures (e.g. joints, fractures)
  - use systemic antibiotics if wound cultures are positive and there are signs of infection; tailor antibiotics as cultures return

Wound Exudate Characteristics
- Serous drainage (plasma): thin; clear or light yellowish
- Sanguineous drainage (fresh blood): bright red
- Serosanguineous drainage (mix of blood and serous fluid): thin and watery; pale red to pink
- Purulent drainage (infection): thick and opaque; white, yellow, or pale green

Management of Late Contaminated Wounds (>24 h)
- tetanus prophylaxis
- irrigation and debridement
- systemic antibiotics if there are clinical signs of infection
- closure: final closure via secondary intention (most common), delayed wound closure (3° closure), skin graft, or flap

Table 8. Risks for Tetanus Infection

Wound Characteristics	Tetanus-Prone	Not Tetanus-Prone
Time Since Injury	>6 h	<6 h
Depth of Injury	>1 cm	<1 cm
Mechanism of Injury	Crush, burn, gunshot, frostbite, puncture through clothing, farming injury	Sharp cut (e.g. clean knife, clean glass)
Devitalized Tissue	Present	Not present
Contamination (e.g. soil, dirt, saliva, grass)	Yes	No
Retained Foreign Body	Yes	No

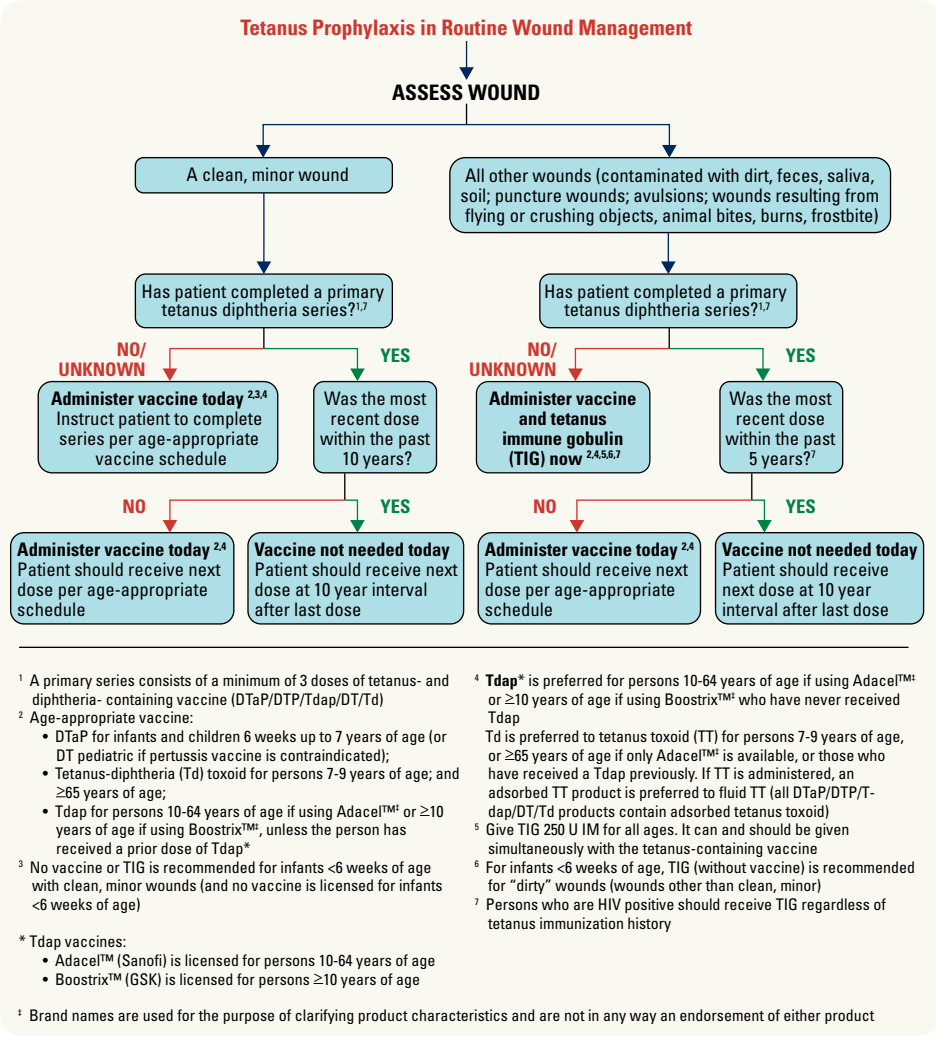

Figure 16. Tetanus immunization recommendations

BITES

- see Emergency Medicine, ER47

Dog and Cat Bites

- pathogens: *Pasteurella multocida, Staphylococcus aureus, Streptococcus viridans*
- **investigations**
  - radiographs prior to therapy to rule out foreign body (e.g. tooth) or fracture
  - culture for aerobic and anaerobic organisms, Gram stain
- **treatment**: Clavulin® (amoxicillin + clavulanic acid) 500 mg PO q8 h started immediately
  - consider rabies prophylaxis if animal has symptoms of rabies or unknown animal
    - ± rabies Ig (20 IU/kg around wound, or IM) and 1 of the 3 types of rabies vaccines (1.0 mL IM in deltoid, repeat on days 3, 7, 14, 28)
- irrigation with debridement
- healing by secondary intention is mainstay of treatment
- only consider primary closure for bite wounds on the face if large and done in OR; otherwise primary closure is contraindicated
- contact Public Health if animal status unknown

Human Bites

- pathogens: *Staphylococcus aureus* > GAS> *Eikenella corrodens* > *Bacteroides*
- serious, as mouth has 109 microorganisms/mL, which can get trapped in joint space when fist unclenches and overlying skin forms an air-tight covering ideal for anaerobic growth – can lead to septic arthritis
- **investigations**
  - radiographs prior to therapy to rule out foreign body (e.g. tooth) or fracture
  - culture for aerobic and anaerobic organisms, Gram stain

- **treatment**
  - if joint infected, urgent surgical exploration of joint, drainage, and debridement of infected tissue
  - otherwise, can be managed with I & D and antibiotic treatment in ER
  - if due to MSSA, Cefazolin 2 g IV q8h or (if penicillin allergy or MRSA) vancomycin 15 mg/kg IV q12h + secondary closure
  - splint

Dressings

- dressing selection depends on the wound characteristics, goal of dressing, and surgeon preference
  - as the wound progresses through healing, it will require different types of dressings; therefore, routine inspection is recommended
    - principles of dressing clean vs. infected wounds
      - clean wounds can be dressed with non-adherent dressing (which is non-adhering to epithelialising tissue); requires secondary dressing
      - infected wounds may need debridement, antibiotics, and antimicrobial dressings (i.e. iodine gauze and silver-containing dressings)
    - moist vs. dry wounds
      - purpose of dressings should be to promote moist wound healing i.e. moistening dry wounds or drying (removing excess exudate/blood) wet wounds
    - wide-based vs. cavitary/tunneling wounds
      - cavitary or tunneling wounds (i.e. through a fascial layer) can be packed with loose, large, and radiopaque packing materials
    - negative pressure wound therapy uses wound dressings that apply subatmospheric pressure to the wound site to promote blood flow to the region and enhance the healing process. The resultant pressure gradient promotes fluid transport from the wound bed and interstitial space to reduce wound edema
    - indications: diabetic foot ulcers, reconstructive surgery, and following debridement of acute or chronic wounds
    - contraindications: wounds with exposed vital structures (i.e. organs, blood vessels, vascular grafts) and malignant tissue

Table 9. Wound Dressings and Their Use

Dressing Type	Example	Use
Low adherent dressings	Jelonet, tullegras, mepilex, mepitel	Flat and shallow wounds with low exudates
Semipermeable films	Mefilm, Tegaderm, Bioclusive	Wounds in difficult anatomic sites (ex: over joints)
Hydrocolloids	CombiDERM, Tegasorb, Aquacel	Hydrocolloid sheets: flat, shallow wounds with low exudate; difficult areas (elbow, heel, etc.) Hydrofibre: flat wounds, cavities, sinuses; medium – high exudate wounds
Antimicrobial	Acticoat, Avance, Iodosorb	Locally infected wounds

Reconstruction

RECONSTRUCTION LADDER

Definition

- an approach to wound management with successively more complex methods of treatment
- surgeons should start with the least complex method and progressively increase in complexity as appropriate

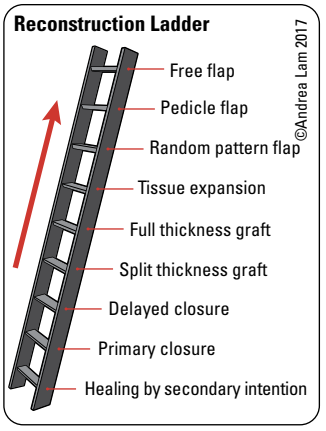

Figure 17. Reconstructive ladder - in order of increasing complexity

SKIN GRAFTS

Definition

- tissue composed of epidermis and varying degrees of dermis, that does not carry its own blood supply. Survival requires the generation of new blood vessels from the recipient site bed

Donor Site Selection

- must consider size, hair pattern, texture, thickness of skin, and colour (facial grafts best if taken from "blush zones" - harvest sites above clavicle where colour match for full thickness grafts is optimized (e.g. pre/post auricular or neck))
- partial thickness grafts usually taken from inconspicuous areas (e.g. buttocks, lateral thighs, etc.)

Partial Thickness Skin Graft Survival

- 3 phases of skin graft "take"
  1. plasmatic imbibition: diffusion of nutrition from recipient site (first 48 h)
  2. inosculation: growth of vessels from bed and graft toward each other (d 2-3)
  3. neovascular ingrowth: growth of new vessels which vascularize graft (d 3-5)

- requirements for graft survival
  - well-vascularized bed (recipient site). Examples of unsuitable beds include heavily irradiated wounds and infected wounds
  - coagulation begins as soon as graft is placed on bed
  - good contact between graft and recipient bed. Staples, sutures, splinting, and pressure dressings are used to prevent movement/ shearing of graft and hematoma or seroma formation
  - low bacterial count at recipient site (<105/cm3, to prevent infection)
- common reasons for graft loss: hematoma/seroma, infection, mechanical force (e.g. shearing, pressure)

Classification of Skin Grafts

1. by species
   - autograft: from same individual
   - allograft (homograft): from same species, different individual
   - xenograft (heterograft): from different species (e.g. porcine)
2. by thickness: see Table 10

Table 10. Skin Grafts

	Split Thickness Skin Graft	Full Thickness Skin Graft
Definition	Epidermis and part of dermis	Epidermis and all of dermis
Donor Site	More sites	Donor sites limited by the ability to use primary closure
Healing of Donor Site	Re-epithelialization via dermal appendages in wound edges	Primary closure
Re-Harvesting	~10 d (faster on scalp)	N/A
Graft Take	More reliable and better survival; shorter nutrient diffusion distance	Lower rate of survival (thicker, slower revascularization)
Contraction*	Less 1° contraction, greater 2° contraction (less with thicker graft)	Greater 1° contraction, less 2° contraction
Aesthetic	Poor	Good
Advantages	Takes well in less favourable conditions	Resists contraction, better colour match
	Can cover a larger area	May use on face and fingers
	Can be meshed for greater area	
	Allows for extravasation of blood/serum	
	Large number of donor sites	
Disadvantages	Contracts significantly, abnormal pigmentation, high susceptibility to trauma, donor site scar, requires well vascularized bed	Requires well vascularized bed
Uses	Large areas of skin, granulating tissue beds	Face (colour match), site where thick skin or decreased contracture is desired (e.g. finger)

*1° contraction: immediate reduction in size upon harvesting; 2° contraction: reduction in size once graft placed on wound bed and healing has occurred

Meshed Grafts

- split thickness grafts can be meshed after harvest by a mesher to a variety of ratios
- **advantages**
  - prevents accumulation of fluids (e.g. hematoma, seroma)
  - covers a larger area
  - best for contaminated recipient site
- **disadvantages**
  - poor cosmesis ("alligator hide" appearance)
  - has greater secondary contraction than full thickness grafts (see Table 10)

OTHER GRAFTS

Table 11. Various Tissue Grafts

Graft Type	Use	Preferred Donor Site
Bone (Vascularized or Non-Vascularized)	Repair rigid defects	Cranial, rib, iliac, fibula, scapula
Cartilage	Restore contour of ear and nose	Ear, nasal septum, costal cartilage
Tendon	Repair or replace a damaged tendon	Palmaris longus, plantaris (present in 85% of population)
Nerve	Conduit for regeneration across nerve gap	Sural, antebrachial cutaneous, medial brachial cutaneous
Vessel	Bridge vascular gaps	Forearm or foot vessels for small vessels, saphenous vein for larger vessels; veins are typically used for any vessel graft
Dermis	Contour restoration (± fat for bulk); not used often	Groin, abdomen, thigh
Fat	Contour restoration	Abdomen, thighs, buttocks

FLAPS

- **definition**: tissue of varying composition (muscle alone, skin and subcutaneous tissue, bone alone with vascular supply, etc.), that has a known blood supply (random, pedicled, or named); not dependent on neovascularization, unlike a graft
- may consist of: skin, subcutaneous tissue, fascia, muscle, tendon, bone, other tissue (e.g. omentum)
- **classification**: based on tissue composition, blood supply to skin (random, axial), location of the donor site (local, regional, distant), etc.
- indications for flaps
  - replaces tissue loss due to trauma or surgery (reconstruction)
  - provides skin and soft tissue coverage through which surgery can be carried out later
- **complications**: flap loss due to hematoma, seroma, infection, poor flap design, extrinsic compression (dressing too tight) or vascular failure/thrombosis, fat necrosis (in free and pedicled flaps)

Random Pattern Flaps

- blood supply by dermal and subdermal plexus to skin and subdermal tissue with random vascular supply
- limited length:width ratio to ensure adequate blood supply
- flap choice is often a combination of available tissue, type of tissue needed, location of reconstruction site with respect to donor site, blood supply, ability to close the donor site, and surgeon preference
- **types**
  - **rotation**: semicircular tissue rotated around a pivot point for defect closure; commonly used on sacral pressure sores, scalp, and cheek defects (height of triangular defect: radius of flap curve should be 0.5-1:1)
  - **transposition**: tissue is transposed (i.e. lifted up from its native location and brought into the defect) around a pivot point from one location to another; commonly used on certain areas of the face using adjacent areas of excess skin laxity
  - **Z-plasty**: two triangular flaps are designed around a scar to reorient a scar, lengthen the line of a scar, or to break up a scar
  - **advancement flaps (V-Y, Y-V):** defect is closed with unidirectional tissue advancement
    - **single/bipedicle V-Y flaps**: wounds with lax surrounding tissue; the pedicle flap is attached to the donor site via a pedicle containing the blood supply

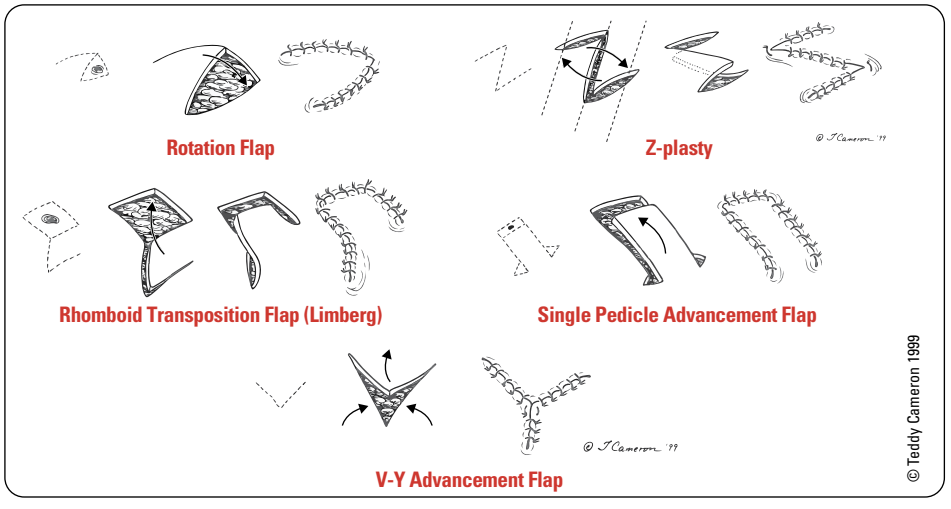

Figure 18. Wound care flaps – random pattern

Axial Pattern Flaps (Arterialized)
- flap contains a well-defined artery and vein
- allows greater length:width ratio (5-6:1)
- **types**
  - **peninsular flap**: skin and vessel intact in pedicle
  - **island flap**: vessel remains intact, but is skeletonized such that the pedicle is better defined
  - **free flap**: segment of tissue with named blood supply (artery and vein) that can be harvested with that blood supply and re-anastomosed in a different anatomical location by microsurgical techniques
- can be sub-classified according to categories such as tissue type, blood supply type, and calibre of vessels
  - e.g. myogenic, myocutaneous, fasciocutaneous

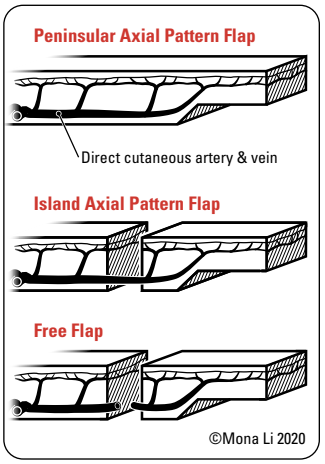

Figure 19. Axial/arterial pattern flaps

Free Flaps
- transplanting expendable donor tissue from one part of the body to another by isolating and dividing a dominant artery and vein to a flap, and performing a microsurgical anastomosis between these and the vessels in the recipient wound
- types: muscle and skin (common), bone, jejunum, omentum, fascia, or any combination of tissue where a common blood supply can be harvested to provide vascular supply to all the tissue types
- e.g. radial forearm, scapular, latissimus dorsi

Table 12. Characteristics of Healthy Free Flap

Characteristic	Normal	Arterial Insufficiency	Venous Insufficiency
Colour*	Pink	Pale	Purple or blue
Temperature	Warm	Cool	Warm or cool
Arterial Pulse (Doppler)	+	–	±
Turgor	Soft, but with some firmness	Decreased tissue firmness	Increased (tissue firmness with tissue stiffness)
Capillary Refill	2-5 s	>5 s	<2 s

*Variation depending on patient's skin colour

Vascularized Composite Allotransplantation (i.e. composite tissue allotransplantation)
- considered free flaps because it is a functional and vascularized construct; vessels are anastomosed, as well as the nerves
- similar to solid organ transplantation, although VCA involves the transplantation of a composite of tissue (skin, fat, muscle, nerve, and vessels) from one individual to another, after matching sex and blood ± HLA type
- skin is highly immunogenic, containing effector T cells and antigen presenting cells which can mount a proinflammatory state and contribute to allograft rejection; regulatory T cells (Tregs) can modulate effector T cell inflammation through inhibitory cytokines (e.g. TGF-β, IL-10)
- patients require immunosuppression therapy
  - induced with antithymocyte globulin and basiliximab (anti-T cell antibodies)
  - maintained with tacrolimus, mycophenolate mofetil, and prednisone
- acute rejection appears to affect the skin first; treatment consists of increased oral or IV steroids, mono/polyclonal antibodies, and topical immunosuppressants

Soft Tissue Infections

Erysipelas

Definition
- acute skin infection of the upper dermis and superficial lymphatics (more superficial than cellulitis)

Etiology
- typically caused by GAS

Clinical Features
- intense erythema, induration, and sharply demarcated borders (differentiates it from other skin infections)

Treatment
- penicillin or first-generation cephalosporin (e.g. cefazolin or cephalexin)

Cellulitis

Definition
- non-suppurative infection of skin and subcutaneous tissues

Etiology
- skin flora are most common organisms: *Staphylococcus aureus*, GAS
- immunocompromised: Gram-negative rods and fungi

Clinical Features
- source of infection
  - trauma, recent surgery
  - PVD, DM – xerotic skin in feet/toes
  - foreign bodies (IV, orthopaedic pins)
- systemic symptoms (fever, chills, malaise)
- pain, tenderness, edema, erythema with poorly defined margins, regional lymphadenopathy
- can lead to ascending lymphangitis (common in GAS; visible red streaking in skin proximal to area of cellulitis)

Investigations
- CBC, blood cultures
- culture a collection/aspirate from wound if open wound

Treatment
- antibiotics: first line – cephalexin 500 mg PO q6 h or cloxacillin 500 mg PO q6 h x 7 d; if complicated (e.g. lymphangitis, DM, severe infection, oral antibiotic therapy failure), consider IV cefazolin 1-2 g q8 h or IV cloxacillin, IV penicillin. All patients should have reassessment in 48 h for resolution if on an oral antibiotic
- outline area of erythema to monitor success of treatment
- immobilize upper and lower extremities; consider non-weight bearing for lower extremities

Necrotizing Fasciitis

Definition
- rapidly spreading, very painful infection of the fascia with necrosis of surrounding tissues
- some bacteria create gas that can be felt as crepitus and can be seen on x-rays (subcutaneous emphysema)
- infection spreads rapidly along deep fascial plane and is limb-and life-threatening

Etiology
- Type I: polymicrobial (more common in immunocompromised)
- Type II: monomicrobial, usually GAS (more common in healthy patients)

Risk Factors
- immunocompromised, DM, obesity, IV drug use, age >50 yr

Clinical Features
- pain out of proportion to clinical findings and beyond border of erythema
- edema, tenderness, ± crepitus (subcutaneous gas from anaerobes), ± sepsis-type symptoms (e.g. nausea, fever, diarrhea, dizziness, malaise)
- overlying skin changes including blistering and ecchymoses
- patients may look deceptively well at first, but have some physiological abnormalities on initial labs and may rapidly become very sick/toxic
- late findings:
  - skin turns dusky blue and black (secondary to thrombosis and necrosis)
  - induration, formation of bullae
  - cutaneous gangrene, subcutaneous emphysema

Investigations
- a clinical diagnosis
- CT scan only if suspect it is not necrotizing fasciitis (looking for abscess, gas collection, myonecrosis and possible source of infection)
- severely elevated CK: usually means myonecrosis (late sign)
- bedside incision, exploration, and incisional biopsy when ruling out conditions, clinical feature is not supportive, or difficult exam
- during incisional biopsy, often see "dishwater pus" (GAS) and a hemostat easily passed along fascial plane (fascial biopsy to rule out in equivocal situations)

Treatment
- vigorous resuscitation (ABCs)
- urgent surgical debridement: remove all necrotic tissue, copious irrigation with plans for repeat surgery in 24-48 h
- IV antibiotics: as appropriate for clinical scenario; consider penicillin 4 million IU IV q4 h and clindamycin 900 mg IV q6 h until final cultures available (the combination can be synergistic if GAS) or vancomycin and clindamycin
- postoperative ICU admission and infectious disease consult after urgent surgical debridement by plastic surgery

Ulcers

Lower Limb Ulcers

Traumatic Ulcers (Acute)
- failure of wound to heal, usually due to compromised blood supply and unstable scar, secondary to pressure or bacterial colonization/infection
- usually over bony prominence ± edema ± pigmentation changes ± pain
- treatment, in consultation with vascular surgery
  - any debridement of ulcer and compromised tissues must be preceded by ABIs and vascular Doppler
  - ulcers or compromised tissues left to heal by secondary intention with dressings may need reconstruction with local or distant flap in select cases; vascular status of limb must be assessed clinically and via vascular studies (i.e. ABI, duplex Doppler)

Non-Traumatic Ulcers (Chronic)

Table 13. Venous vs. Arterial vs. Diabetic Ulcers

Characteristic	Venous (70% of vascular ulcers)	Arterial	Diabetic
Cause	Valvular incompetence Venous HTN	2° to small and/or large vessel disease (be aware of risk factors)	Peripheral neuropathy: decreased sensation Atherosclerosis: microvascular disease
History	Dependent edema, trauma Rapid onset ± thrombophlebitis, varicosities	Arteriosclerosis, claudication Usually >45 yr Slow progression	DM Peripheral neuropathy Trauma/pressure
Common Distribution	Medial malleolus ("Gaiter" locations)	Distal locations (e.g. lower limb, feet)	Pressure point distribution (more likely metatarsal heads)
Appearance	Yellow exudates Granulation tissue Varicose veins Brown discolouration of surrounding skin	Pale/white, necrotic base ± dry eschar covering	Necrotic base
Wound Margins	Irregular	Even ("punched out")	Irregular or "punched out" or deep
Depth	Superficial	Deep	Superficial/deep
Surrounding Skin	Venous stasis discolouration (brown)	Thin, shiny, dry skin; hairless, cool	Thin, dry skin ± hyperkeratotic border Hypersensitive/ischemic
Pulses	Normal distal pulses	Decreased or no distal pulses	Decreased pulses likely (take caution in calcified vessels)
Vascular Exam	ABI >0.9 Doppler; abnormal venous system	ABI <0.9 Pallor on elevation, rubor on dependency Delayed venous filling	ABI is inaccurately high (due to PVD) Usually associated with arterial disease (microvascular/macrovascular disease)
Pain	Moderately painful Increased with leg dependency, decreased with elevation No rest pain	Extremely painful Decreased with dependency, increased with leg elevation and exercise (claudication) Rest pain	Painless (if neuropathy) No claudication or rest pain Associated paresthesia, anesthesia
Treatment	Rest, leg elevation Compression at 30 mmHg (stockings or elastic bandages) (Ensure ABI is safe for compression) Moist wound dressings ± topical, systemic antibiotics if infected ± wound dressings	Rest, no elevation, no compression Moist wound dressing ± topical and/or systemic antibiotics if infected Modify risk factors (smoking, diet, exercise, etc.) Vascular surgical consultation (angioplasty or bypass) Treat underlying conditions (DM, proximal arterial occlusion, etc.)	Control DM Careful wound care Foot care Orthotics, off-loading Early intervention for infections (topical and/or systemic antibiotics if infected) Vascular surgical consultation

In patients with DM, ABI can be falsely normal due to incompressible arteries secondary to plaques/calcification

Pressure Ulcers

Common Sites
- over bony prominences; 95% on lower body

Stages of Development
1. hyperemia: disappears 1 h after pressure removed
2. ischemia: follows 2-6 h of pressure
3. necrosis: follows >6 h of pressure
4. ulcer: necrotic area breaks down

Classification (National Pressure Ulcer Advisory Panel 2014)
- Stage I: non-blanchable erythema present >1 h after pressure relief, skin intact
- Stage II: partial-thickness skin loss
- Stage III: full-thickness skin loss into subcutaneous tissue
- Stage IV: full-thickness skin loss into muscle, bone, tendon, or joint
  - if an eschar is present, must fully debride before staging possible
- Stage X: unstageable

Prevention
- clean and dry skin, frequently reposition), special beds or pressure relief surface, proper nutrition, activity, early identification of individuals at risk (e.g. immobility, incontinence, paraplegia, immunocompromised, DM, etc.), treatment of underlying medical conditions

Treatment
- treatment plan individualized to patient
- 4 main principles:
  - preventative measures (pressure relief, assess for pressure points e.g. wheelchairs; manage continence issues, divert contaminants e.g. urine and feces, ensure appropriate nutrition)
  - treatment of underlying medical issues including nutrition
  - moisture reduction and pressure relief
  - wound bed preparation and treatment
- systemic antibiotics for infections
- assess for possible reconstruction

Complications
- cellulitis, osteomyelitis, sepsis, gangrene

A Nutritional Formula Enriched with Arginine, Zinc, and Antioxidants for the Healing of Pressure Ulcers: A Randomized Trial
Ann Intern Med 2015;162(3):167-174
Purpose: To determine whether supplementation with arginine, zinc, and antioxidants within a high-calorie, high-protein formula improves pressure ulcer healing.
Methods: 200 adult patients from long-term care and home care services with stage II, III, and IV pressure ulcers received either an energy-dense, protein-rich oral formula enriched with arginine, zinc, and antioxidants or an equal volume of an isocaloric, isonitrogenous formula for 8 wk.
Results: Supplementation with the enriched formula resulted in a greater reduction in pressure ulcer area. A more frequent reduction in area of 40% or greater at 8 wk was also seen.
Conclusion: Among malnourished patients with pressure ulcers, 8 wk of supplementation with an oral nutritional formula enriched with arginine, zinc, and antioxidants improves pressure ulcer healing.

Burns

Burn Injuries

Causal Conditions
- thermal (flame contact, scald)
- chemical
- radiation (UV, medical/therapeutic)
- electrical

Most Common Etiologies
- children: scald burns
- adults: flame burns

Table 14. Skin Function and Burn Injury

Skin Function	Consequence of Burn Injury	Intervention Required
Thermoregulation	Prone to lose body heat	Must keep patient covered and warm
Control of Fluid Loss	Loss of large amounts of water and protein from the skin and other body tissues	Adequate fluid resuscitation is imperative
Mechanical Barrier to Bacterial Invasion and Immunological Organ	High-risk of infection	Antimicrobial dressings (systemic antibiotics if signs of specific infection present) Tetanus prophylaxis if not already administered

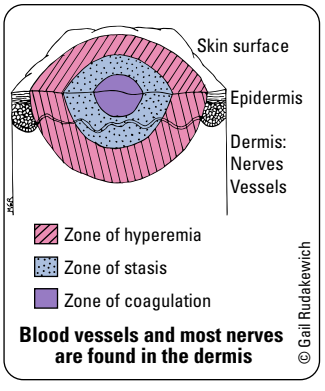

Figure 20. Zones of thermal injury

Pathophysiology of Burn Wounds

- amount of tissue destruction is based on temperature, time of exposure, and specific heat of the causative agent
- zone of hyperemia: vasodilation from inflammation; entirely viable, cells recover within 7 d; contributes to systemic consequences seen with major burns
- zone of stasis (edema): decreased perfusion; microvascular sludging and thrombosis of vessels results in progressive tissue necrosis → cellular death in 24-48 h without proper treatment
  - factors favouring cell survival: moist, aseptic environment, rich blood supply
  - zone where appropriate early intervention has most profound effect in minimizing injury
- zone of coagulation (ischemia): no blood flow to tissue → irreversible cell damage → cellular death/necrosis

Diagnosis and Prognosis

- burn size
  - % of TBSA burned: rule of 9s for 2° and 3° burns only (children <10 yr use Lund-Browder chart)
  - for patchy burns, surface area covered by patient's palm (fingers adducted) represents approximately 1% of TBSA
- age: more complications if <3 yr or >60 yr
- depth: difficult to assess initially – history of etiologic agent and time of exposure helpful (see Table 15, PL20)
- location: face and neck, hands, feet, perineum are critical areas requiring special care of a burn unit (see *Indications for Transfer to Burn Centre*, PL20)
- inhalation injury: can severely compromise respiratory system, affect fluid requirement estimation (underestimate), mortality secondary to ARDS
- associated injuries (e.g. fractures)
- comorbid factors can exacerbate extent of injury (e.g. concurrent disability, alcoholism, seizure disorders, chronic renal failure, other trauma)

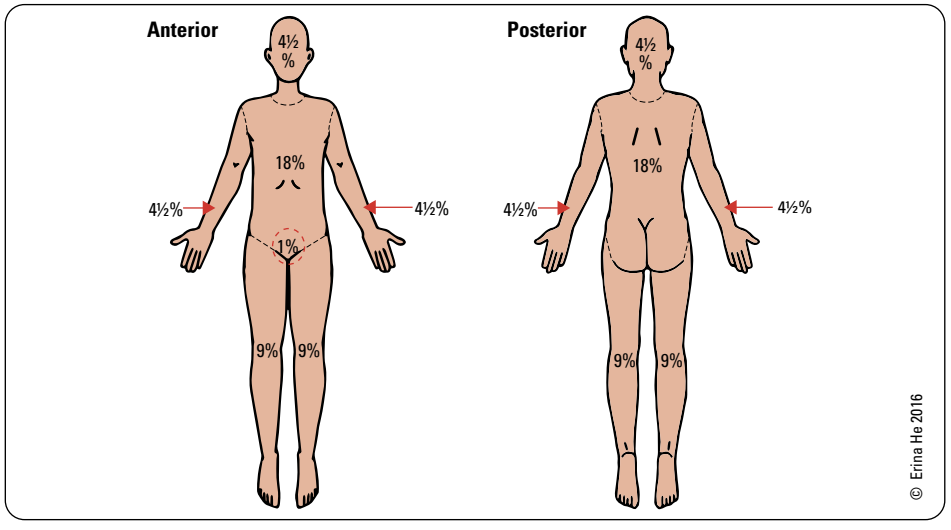

Figure 21. Rule of 9s for TBSA

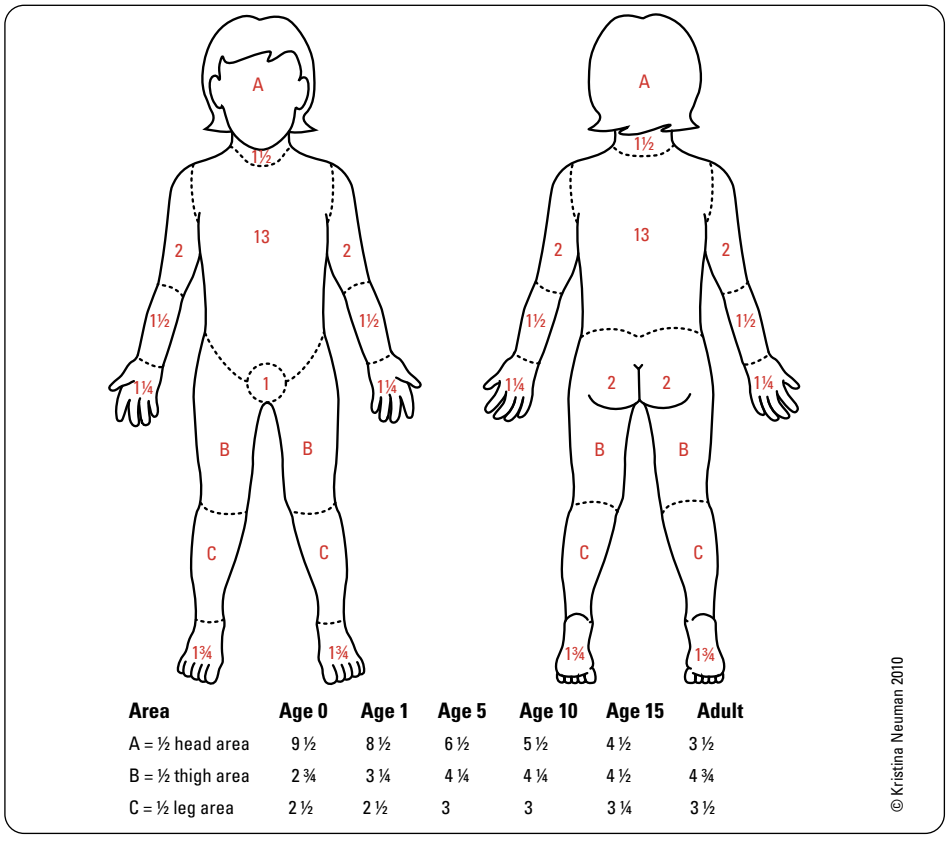
Prognosis best determined by burn size (TBSA), age of patient, presence/absence of inhalation injury

Circumferential burns can restrict respiratory excursion and/or blood flow to extremities and require escharotomy

TBSA does not include areas with 1° burns



Area	Age 0	Age 1	Age 5	Age 10	Age 15	Adult
A = ½ head area	9 ½	8 ½	6 ½	5 ½	4 ½	3 ½
B = ½ thigh area	2 ¾	3 ¼	4 ¼	4 ¼	4 ½	4 ¾
C = ½ leg area	2 ½	2 ½	3	3	3 ¼	3 ½

Figure 22. Lund-Browder diagram

Table 15. Burn Depth (1st, 2nd, 3rd degree)

Nomenclature	Traditional Nomenclature	Depth	Clinical Features
Erythema/Superficial	First degree	Epidermis	Painful, sensation intact, erythema, blanchable
Superficial-Partial Thickness	Second degree	Into superficial (papillary) dermis	Painful, sensation intact, erythema, blisters with clear fluid, blanchable, hair follicles present
Deep-Partial Thickness	Second degree	Into deep (reticular) dermis	Insensate, difficult to distinguish from full thickness, does not blanch, some hair follicles still attached, softer than full thickness burn
Full Thickness	Third degree	Through epidermis and dermis	Injury to underlying tissue structures (e.g. muscle, bone) Insensate (nerve endings destroyed), hard leathery eschar that is black, grey, white, or cherry red in colour; hairs do not stay attached, may see thrombosed veins
	Fourth degree	Injury to underlying tissue structures (e.g. muscle, bone)	

Indications for Transfer to Burn Centre

American Burn Association Criteria

- patients with partial or full-thickness burns that involve the hands, feet, genitalia, face, eyes, ears, and/or major joints or perineum
- partial thickness burns ≥20% TBSA in patients 10-50 yr
- partial thickness burns ≥10% TBSA in children ≤10 or adults ≥50 yr
- full thickness burns ≥5% TBSA in patients of all ages
- electrical burns including lightning (internal injury underestimated by TBSA), and chemical burns
- inhalation injury (high risk of mortality and may lead to respiratory distress)
- burn injuries in patients with medical comorbidities which could complicate management and recovery
- any patients with simultaneous trauma and burns should be stabilized for trauma first, then triaged appropriately to burn centre
- any patients with burn injury who will require special emotional, social, and rehabilitation intervention
- children with burns in a hospital not equipped with paediatric care specialists

Acute Care of Burn Patients

- adhere to ATLS protocol
- resuscitation using Parkland formula to treat fluid loss secondary to injury and cardiac output. Parkland formula is a starting estimate and patients may require more volume. Other formulas exist, but the Parkland formula is predominantly used in North America (see Table 16)
- extra fluid administration required if:
  - burn >80% TBSA
  - 4° burns
  - associated traumatic injury
  - electrical burn
  - inhalation injury
  - delayed start of resuscitation
  - paediatric burns
- monitor resuscitation
  - urine output is best measure: maintain at >0.5 cc/kg/h (adults) and 1.0 cc/kg/h in children <12 yr
  - maintain a clear sensorium, HR <120/min, MAP >70 mmHg
- burn-specific care
  - escharotomy in circumferential extremity burns, including digits
  - prevent and/or treat burn shock: 2 large bore IVs for fluid resuscitation
  - insert Foley catheter to monitor urine output
  - identify and treat immediate life-threatening conditions (e.g. inhalation injury, CO poisoning)
  - determine TBSA affected first, since depth is difficult to determine initially (easier to determine after 24 h)
- tetanus prophylaxis if needed
  - all patients with burns >10% TBSA, or deeper than superficial-partial thickness, need 0.5 cc tetanus toxoid
  - also give 250 U of tetanus Ig if prior immunization is absent/unclear, or the last booster >10 yr ago
- baseline laboratory studies (Hb, U/A, BUN, CXR, electrolytes, Cr, glucose, CK, ECG, cross-match if traumatic injury, ABG, carboxyhemoglobin)
- cleanse, debride, and treat the burn injury (antimicrobial dressings)
- early excision and grafting are standard of care and important for outcome

Respiratory Problems

- 3 major causes
  - burn eschar encircling chest
    - distress may be apparent immediately
    - perform escharotomy to relieve constriction
  - CO poisoning
    - may present immediately or later
    - treat with 100% O_2 by facemask (decreases half-life of carboxyhemoglobin from 210 to 59 min) until carboxyhemoglobin <10%
  - smoke inhalation leading to pulmonary injury
    - chemical injury to alveolar basement membrane and pulmonary edema (insidious onset)
    - risk of pulmonary insufficiency (up to 48 h) and pulmonary edema (48-72 h)
    - watch for secondary bronchopneumonia (3-25 d) leading to progressive pulmonary insufficiency
    - intubate patient with any signs of inhalation injuries

Burn Wound Healing

Table 16. Burn Shock Resuscitation (Parkland Formula)

Parkland Formula	
Hour 0-24	4 cc x mass in kg x % TBSA with 1/2 of total in first 8 h from time of injury and 1/2 of total in next 16 h from time of injury
Hour 24-30	0.35-0.5 cc plasma x mass in kg x % TBSA
>Hour 30	D5W at rate to maintain normal serum sodium

* Remember to add maintenance fluid to resuscitation

Inhalation Injuries 101

Indicators of Inhalation Injury

- Injury in a closed space
- Facial burn
- Singed nasal hair/eyebrows
- Soot around nares/oral cavity
- Hoarseness
- Conjunctivitis
- Tachypnea
- Carbon particles in sputum
- Elevated blood CO levels (i.e. brighter red)
- Suspected inhalation injury requires immediate intubation due to impending airway edema; failure to diagnose inhalation injury can result in airway swelling and obstruction, which, if untreated, can lead to death
- Neither CXR or ABG can be used to rule out inhalation injury
- Direct bronchoscopy now used for diagnosis
- Signs of CO poisoning (headache, confusion, coma, arrhythmias)

Table 17. Burn Wound Healing

Depth	Healing
First Degree	No scarring; complete healing
Second Degree (superficial partial)	Spontaneously re-epithelialize in 7-14 d from retained epidermal structures
	± Residual skin discolouration
	Hypertrophic scarring uncommon; grafting rarely required
Deep Second Degree (deep partial)	Re-epithelialize in 14-35 d from retained epidermal structures
	Hypertrophic scarring frequent
	Grafting recommended to expedite healing
Third Degree (full thickness)	Re-epithelialize from the wound edge
	Grafting/flap necessary to replace dermal integrity and limit hypertrophic scarring
Fourth Degree	Often results in amputations
	If not requiring amputation, needs flap for coverage after debridement (does not re-epithelialize, cannot graft)

Treatment

- three stages
  1. assessment: depth determined
  2. management: specific to depth of burn and associated injuries
  3. rehabilitation
- first degree
  - treatment aimed at comfort
  - topical creams (pain control, keep skin moist) ± aloe
  - oral NSAIDs (pain control)
- superficial second degree/partial thickness
  - daily dressing changes with topical antimicrobials (such as Polysporin®); leave blisters intact unless impaired or over joint and inhibiting motion
- deep second degree/deep partial thickness and third degree/full thickness
  - prevent infection and sepsis (significant complication and cause of death in patients with burns)
    - most common organisms: *S. aureus, P. aeruginosa*, and *C. albicans*
      - day 1-3 (rare): Gram-positive
      - day 3-5: Gram-negative (*Proteus, Klebsiella*)
    - topical antimicrobials: treat colonized wounds (from skin flora, gut flora, or caregiver)
  - remove dead tissue
- surgically debride necrotic tissue, excise to viable (bleeding) tissue

Table 18. Antimicrobial Dressings for Burns

Antibiotic	Pain with Application	Penetration	Adverse Effects
Silver Nitrate (0.5% solution)	None	Minimal	May cause methemoglobinemia, stains (black), leeches sodium from wounds
Nanocrystalline Silver-Coated Dressing (Acticoat®)	None or transient	Medium, does not penetrate eschar	May stain, producing a pseudoeschar or facial discolouration (bluish-gray discolouration; raised liver enzymes
Silver Sulfadiazine (cream) (Flamazine®, Silvadene®)	Minimal	Medium, penetrates eschar	Slowed healing, leukopenia, mild inhibition of epithelialisation; pseudoeschar must be washed off prior to each application
Sulfamylon®	Moderate	Well, penetrates eschar; only used on ears	Mild inhibition of epithelialization, may cause metabolic acidosis with wide application

- early excision and grafting is the mainstay of treatment for deep/full thickness burns
- initial dressing should decrease bacterial proliferation

Risk Factors for Infection of Burn Wounds

Patient Related

Extent >30% TBSA

- Depth: full thickness and deep partial thickness
- Patient age (higher risk with very young and very old)
- Comorbidities
- Wound dryness
- Wound temperature
- Secondary impairment of blood flow to wound
- Acidosis

Microbial Factors

- Density >105 organisms per gram of tissue
- Motility
- Virulence and metabolic products (endotoxin, exotoxin, permeability factors, other factors)
- Antimicrobial resistance

Other Considerations in Burn Management

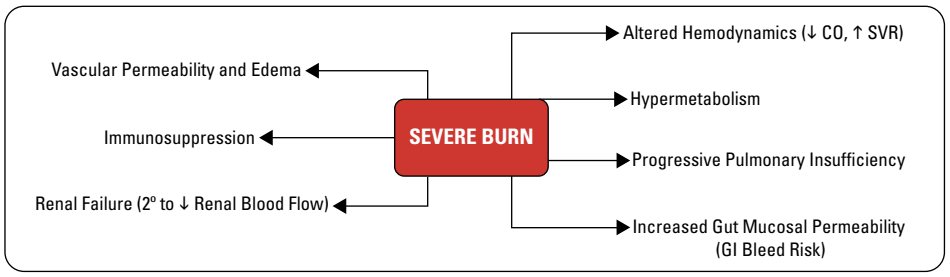


Figure 23. Systemic effects of severe burns

- nutrition
  - hypermetabolism: TBSA >40% have BMR 2-2.5x predicted
  - consider nutritional supplementation e.g. calories, vitamin C, vitamin A, Ca^{2+}, Zn^{2+}, Fe^{2+}
- immunosuppression and sepsis
  - must keep bacterial count <105 bacteria/g of tissue (blood culture may not be positive)
  - signs of sepsis: sudden onset of hyper/hypothermia, unexpected CHF or pulmonary edema, development of ARDS, ileus >48 h post-burn, mental status changes, azotemia, thrombocytopenia, hypofibrinogenemia, hyper/hypoglycemia (especially if burn >40% TBSA)
- GI bleed may occur with burns >40% TBSA (usually subclinical)
  - treatment: tube feeding or NPO if there is a GI bleed, antacids, H2 blockers (preventative)
- renal failure secondary to under resuscitation, drugs, myoglobin, etc.
- progressive pulmonary insufficiency
  - can occur after: smoke inhalation, pneumonia, cardiac decompensation, sepsis
- wound contracture and hypertrophic scarring
  - outcomes optimized with timely wound closure, splinting, pressure garments, and physiotherapy

Special Considerations

CHEMICAL

- major categories: acid burns, alkaline burns, phosphorus burns, chemical injection injuries
- common agents: cement, hydrofluoric acid, phenol, tar
- mechanism of injury: chemical solutions coagulate tissue protein leading to necrosis
  - acids ➔ coagulation necrosis
  - alkalines ➔ saponification followed by liquefactive necrosis
- severity related to: type of chemical (alkali worse than acid), temperature, volume, concentration, contact time, site affected, mechanism of chemical action, degree of tissue penetration
- burns are deeper than they initially appear and may progress with time

Treatment (General)

- ABCs, monitoring
- remove contaminated clothing and brush off any dry powders before irrigation
- irrigation with water for 1-2 h under low pressure (contraindicated in elemental metal burns, such as sodium, potassium, magnesium, and lithium; in these cases, soak in mineral oil instead)
- inspect eyes, if affected: wash with saline and refer to ophthalmology
- inspect nails, hair, and webspaces
- correct metabolic abnormalities and tetanus prophylaxis if necessary
- contact poison control line if necessary
- local wound care 12 h after initial dilution (debridement)
- wound closure same as for thermal burn
- beware of underestimated fluid resuscitation, renal, liver, and pulmonary damage

Table 19. Special Burns and Treatments

Burns	Treatment
Acid Burn	Water irrigation, followed by dilute solution of sodium bicarbonate
Hydrofluoric Acid	Water irrigation; clip fingernails to avoid acid trapping; topical calcium gel ± subcutaneous injection of calcium gluconate ± 10% calcium gluconate IV depending on amount of exposure and pain
Sulfuric Acid	Treat with soap/lime prior to irrigation as direct water exposure produces extreme heat
Tar	Remove with repeated application of petroleum-based antibiotic ointments (e.g. Polysporin®)

ELECTRICAL BURNS

- injury occurs due to flow of current through body, arc flash, or clothing catching on fire
- depth of burn depends on voltage and resistance of the tissue (injury more severe in tissues with high resistance)
- often presents as small punctate burns on skin, with extensive deep tissue damage which requires debridement
- electrical burns require ongoing monitoring (ECG and neurovascular status), as latent injuries can occur
- watch for system-specific damages and abnormalities
  - abdominal: intraperitoneal damage
  - bone: fractures and dislocations especially of the spine and shoulder
  - cardiopulmonary: anoxia, ventricular fibrillation, arrhythmias
  - muscle: myoglobinuria indicates significant muscle damage → compartment syndrome
  - neurological: seizures and spinal cord damage
  - ophthalmology: cataract formation (late complication)
  - renal: acute tubular necrosis resulting from toxic levels of myoglobin and hemoglobin
  - vascular: vessel thrombosis → tissue necrosis (increased Cr, K^+, and acidity), decrease in RBC count (beware of hemorrhages/delayed vessel rupture)

Treatment

- ABCs, primary and secondary survey, treat associated injuries
- beware of cardiac arrhythmias (continue cardiac monitoring)
- monitor: hemochromogenuria, compartment syndrome, urine output
- wound management: topical agent with good penetrating ability (silver sulfadiazine or mafenide acetate)
- debride nonviable tissue early and repeat prn (every 48 h) to prevent sepsis
- amputations frequently required

FROSTBITE

- see Emergency Medicine, ER46

Hand

Traumatic Hand

Table 20. Key Features of the History and Physical Exam of the Injured Hand

	Structure	Examination
HISTORY		
Key Questions	Age	Tetanus status
	Hand dominance	Diabetes
	Occupation	Smoking status
	Time and place of accident	Last oral intake
	Mechanism of injury	
	Initial treatment received	
PHYSICAL EXAM		
Observation	Position of finger	Abnormal cascade (fingers normally slightly flexed and point towards scaphoid), scissoring
	Deformity	Bony protrusions or specific deformities (e.g. mallet, boutonnière, and swan neck deformity)
	Bruising or swelling	May indicate underlying skeletal injury
	Sweating pattern (usually felt more so than from observation)	May indicate denervation
	Anatomical structures beneath	If open laceration, need to explore within wound (under sterile conditions)
Vascular Status	Radial and ulnar arteries	Palpate pulses Allen's test
	Digital arteries	Assess capillary refill (<2-3 s) Doppler ultrasound
	Temperature and skin turgor	For each test, need to compare both sides
Sensory (see Figure 4, PL2)	Median nerve	Volar radial tip of index finger
	Ulnar nerve	Volar ulnar tip of little finger
	Radial nerve	Dorsal web space of the thumb
	Digital nerves	2-point discrimination on both the radial and ulnar side of the DIP creases (static or moving 2-point discrimination)

Compartment Syndrome
Watch out for these signs: tense, painful extremity (worse on passive stretch), paresthesia/paralysis, pallor, and distal pulselessness (often late in process). Intracompartmental pressures can be measured, commonly via needle manometry (generally abnormal pressures are considered to be >30-40 mmHg). Of note, upper and lower extremity pressures are different and comorbidities can result in variability in measured pressures. As such, indication for an emergent fasciotomy is based on clinical diagnosis; if untreated, end result is ischemic contracture of the extremity (Volkmann's contracture)

Approach to Hand Lacerations

TIN AX
Tetanus prophylaxis
Irrigate with NS (copious irrigation and debridement in a timely manner)
NPO (NPO if you are considering replanting or an urgent OR, otherwise most operations are done as elective procedures)
Antibiotic prophylaxis (controversial – most require no antibiotics, mainly needed for lacerations associated with fractures)
X-rays

Table 20. Key Features of the History and Physical Exam of the Injured Hand

	Structure	Examination
Motor Function	Median nerve	Flex DIP of index finger (to test the AIN branch)
		Touch the tip of the index finger to the thumb trying to break through ("OK sign") (to test the AIN branch)
		Thumb to ceiling with palm up (to test the recurrent motor branch)
		Thumb to tip of 5th digit (to test the recurrent motor branch)
	Ulnar nerve	Extrinsic muscles: flex DIP of little finger
		Intrinsic muscles: abduct index finger ("Peace sign") or patient able to hold piece of paper between adducted thumb and index finger and resist pulling ("Froment's sign")
	Radial nerve	Extrinsic muscles: extend thumb ("thumb's up") and wrist
Range of Motion	Tendons, bones, joints, nerves	Assess active and passive range of motion of wrist: extension/flexion/ulnar/radial deviation; finger abduction/adduction/flexion/extension; thumb flexion/extension/abduction/adduction/opposition
Tendons	FDP	Stabilize PIP in extension, ask patient to flex fingers (at DIP)
	FDS	Stabilize non-exam fingers in extension (neutralizes FDP) and ask patient to flex examination finger (at PIP)
Palpation	Bones	Focal tenderness or abnormal alignment
	Joints	Instability may indicate ligamentous injury or dislocation

Allen's Test: You need to exsanguinate the hand by having the patient open and close the hand. Then, while patient's hand is firmly closed, occlude both radial and ulnar arteries. Once fist is open, release one artery and assess collateral flow. The process should be repeated for the other artery

Tissue Resistance to Electrical Current
Nerve < vessel/blood < muscle < skin < tendon < fat < bone

General Management of Hand Injuries (Categorized by Tissue)

Nerves

- test the nerve function BEFORE putting in local anesthesia
- primary repair for a clean injury within 2 wk and without concurrent major injuries; secondary repair if >2 wk (may require nerve graft)
- epineurial repair of all digital nerves with minimal tension
- postoperative: dress wound, elevate hand, and immobilize
- Tinel's sign (cutaneous percussion over the repaired nerve) produces paresthesias and defines level of nerve regeneration
  - Wallerian degeneration occurs in the first 2 wk, which is why there is no Tinel's sign until after this time period
  - a peripheral nerve regenerates at 1 mm/d
  - paresthesias felt at area of percussion because regrowth of myelin (Schwann cells) is slower than axonal regrowth ➡ percussion on exposed free-end of axon generates paresthesia

Hand Exam
- Never blindly clamp a bleeding vessel as nerves are often found in close association with vessels
- Never explore any volar hand wound in the ER
- Arterial bleeding from a volar digital laceration is likely associated with a nerve laceration (nerves in digits are superficial to arteries)

Vessels

- often associated with nerve injury in the digits (anatomical proximity)
- control bleeding with direct pressure and hand elevation
- if digit devascularized, optimal repair within 6 h
- close skin, then dress, immobilize, and splint hand with fingertips visible
- monitor colour, capillary refill, skin turgor, fingertip temperature post-revascularization

Tendons

- most tendon lacerations require repair
- most extensors are repaired in the emergency room, flexors are repaired in the operating room within 2 wk
- see *Tendons*, PL27

Bones

- see *Fractures and Dislocations*, PL28

Nailbed

- subungual hematomas >50% of the nail surface area need to be drained (trephination), done under a digital block by puncturing nail plate
- if suspecting greater severity of injury (e.g. distal phalanx displaced fracture, laceration of nail bed), remove nail plate to examine underlying nailbed under digital block anesthesia
- irrigate wound and nail thoroughly
- suture repair of nailbed with chromic suture
- replace cleaned nail, which acts as a splint for any underlying distal phalangeal fracture and prevents adhesion formation between nail fold and nailbed

Hand Infections

Principles
- trauma is most common cause
- 90% caused by Gram-positive organisms
- most common organisms (in order) – *S. aureus, S. viridans*, GAS, *S. epidermidis*, and *Bacteroides melaninogenicus* (MRSA is becoming more common)

TYPES OF INFECTIONS

Deep Space Infections
- abscess formation in deep spaces of the hand, parona's space, web spaces, or most commonly thenar or midpalmar space

Felon
- **definition**: abscess in the pulp of a fingertip or thumb that occurs following a puncture wound into the pad of the digit; may be associated with osteomyelitis
- **treatment**: elevation, warm soaks, cloxacillin 500 mg PO q6 h (if in early stage); if obvious abscess or pressure on the overlying skin or failure to resolve with conservative measures, then I&D, take cultures/Gram stain, and adjust antibiotics to culture results

Flexor Tendon Sheath Infection
- *Staphylococcus* > *Streptococcus* > Gram-negative rods
- **definition**: abscess within the flexor tendon sheath (flexor tenosynovitis), commonly caused by a penetrating injury and can lead to tendon necrosis and rupture if not treated
- **clinical features**: Kanavel's 4 cardinal signs
  1. point tenderness along flexor tendon sheath from A1 pulley onwards
  2. severe pain on passive extension of digit
  3. fusiform swelling of entire digit
  4. flexed posture (increased comfort)
- **treatment**
  - non-suppurative: antibiotics, resting hand splint and elevation until infection resolves, hand therapy after
  - suppurative (produces pus): I&D in OR

Herpetic Whitlow
- HSV-1, HSV-2
- **definition**: painful vesicle(s) around fingertip or thumb
  - often found in medical/dental personnel and children
- **clinical features**: can be associated with fever, malaise, and lymphadenopathy, prodromal phase
  - patient is infectious until lesion has completely healed
- **treatment**: diagnosed clinically, if in doubt confirm with viral culture/PCR or Tzanck smear, usually self-limited, consider oral acyclovir in severe cases; debridement of these lesions is contraindicated

Paronychia
- acute = *Staphylococcus*; chronic = *Candida*
- **definition**: infection (granulation tissue) of soft tissue around fingernail (within the paronychium and/or beneath eponychial fold)
- **etiology**
  - acute paronychia: a "hangnail", artificial nails, and nail biting
  - chronic paronychia: prolonged exposure to moisture
- **treatment**
  - acute paronychia: warm compresses and oral antibiotics if caught early; if abscess present, drainage with blade (avoid hitting nail bed) and oral/IV antibiotics; if abscess extends to below nail plate, nail plate removal may be required
  - chronic paronychia: antifungals, eponychial marsupialization, nail plate removal may be required

Amputations

Hand or Finger

- emergency management: injured patient and amputated part requires attention
  - patient: x-rays (stump and amputated part), NPO, clean wound and irrigate with NS, dress stump with non-adherent dressing, cover with dry sterile dressing, tetanus and antibiotic prophylaxis (cephalosporin/erythromycin)
  - **amputated part**: x-rays, gently irrigate with RL, wrap amputated part in a NS/RL soaked sterile gauze and place inside waterproof plastic bag, place in a container, then place container on ice
- **indications for replantation**
  - **age**: children often better results than adults
  - **level of injury**: thumb and multiple digit amputations are higher priority; multiple level amputation is a contraindication to replant
  - **nature of injury**: clean cut injuries have greater success; avulsion and crush injuries are relative contraindications to replant
- if replant contraindicated, manage stump with revision amputation
  - involves debriding stump of wound, trimming back the bone and nerve endings, and gently closing the skin
  - commonly done in the ER under digital block

Tendons

Common Extensor Tendon Deformities

Table 21. Extensor Tendon Deformities

Injury	Definition	Zone	Etiology/Clinical Features	Treatment
Mallet Finger	DIP flexed with loss of active extension	1	There are bony and non-bony mallets Bony: Fracture of distal phalanx distal to tendon insertion Non-bony: Forced flexion of the extended DIP leading to extensor tendon rupture at DIP (e.g. sudden blow to tip of the finger)	Splint DIP in extension for 6 wk, followed by 2 wk of night splinting; if inadequate improvement after 6 wk, check splinting routine and recommend 4 more wk of continuous splinting
Boutonnière Deformity	PIP flexed, DIP hyperextended	3	Injury or disease affecting the extensor tendon insertion into the dorsal base of the middle phalanx Associated with RA or trauma (laceration, volar dislocation, acute forceful flexion of PIP)	Splint PIP in extension and allow active DIP motion
Swan Neck Deformity	PIP hyperextended, DIP flexed	1,3	Trauma (PIP volar plate injury) Associated with RA and old, untreated mallet deformity Splint to prevent PIP hyperextension or DIP flexion	Corrective procedures involve tendon rebalancing or arthrodesis/arthroplasty

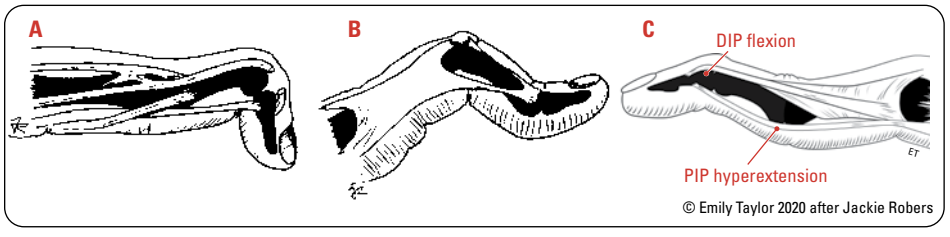

Figure 24. Extensor tendon deformities: (A) Mallet finger deformity (B) Boutonnière deformity (C) Swan neck deformity

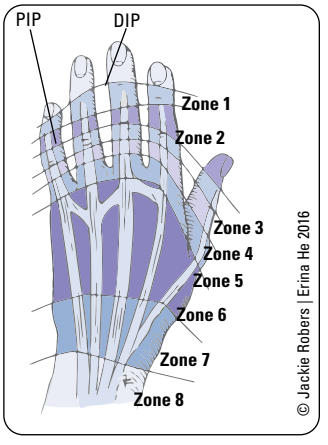

Figure 25. Zone of extensor tendon injury (odd numbered zones fall over a joint)

De Quervain's Tenosynovitis

- **definition**: tenosynovitis is inflammation of the tendon and/or its sheath. Most common is De Quervain's tenosynovitis (inflammation of the extensor tendons in the 1st dorsal compartment (APL and EPB))
- **clinical features**
  - positive Finkelstein's test (pain over the radial styloid induced by making fist, with thumb in palm, and ulnar deviation of wrist)
  - pain localized to the 1st extensor compartment
  - tenderness and crepitation over radial styloid may be present
  - differentiate from CMC joint arthritis (CMC joint arthritis will have a positive grind test, whereby crepitus and pain are elicited by axial pressure to the thumb)
- **treatment**
  - mild: NSAIDs, splinting, and steroid injection into the tendon sheath
  - severe: surgery to open 1st dorsal compartment and release stenotic tendon sheaths of APL and EPB

Ganglion Cyst
- **definition**
  - fluid-filled synovial lining that protrudes between carpal bones or from a tendon sheath; most commonly carpal in origin
  - most common soft tissue tumour of hand and wrist (60% of masses)
- **clinical features**
  - most commonly on the dorsal wrist overlying the scapholunate ligament, followed by the volar surface of the wrist overlying the radioscaphoid or scaphotrapezial joints
  - 3 times more common in women than in men
  - more common in younger individuals (2nd to 4th decades)
  - can be large or small – may drain internally so size may wax and wane
  - often non-tender, although tenderness increased when cyst is smaller (from increased pressure within smaller cyst sac)
- **treatment**
  - conservative treatment: observation and reassurance; advise patient against rupturing cyst
  - aspiration (recurrence rate 30-60% within one yr, risk of damaging nearby neurovascular structures)
  - steroid injection if painful (done in combination with aspiration, as results alone are no better than aspiration)
  - consider operative excision of cyst and stalk (recurrence rate 5.9% for dorsal wrist ganglion, 30% for volar)

Common Flexor Tendon Deformities
- flexor tendon zones (important for prognosis of tendon lacerations)
- "no-man's land" (zone 2)
  - between distal palmar crease and mid-middle phalanx
  - zone where superficialis and profundus lie ensheathed together
  - recovery of glide very difficult after injury

Stenosing Tenosynovitis (trigger finger/thumb)
- **definition**: inflammation and thickening of tendon or tendon sheath/pulley (most commonly at A-1 pulley near MCP), preventing smooth gliding of tendon through the sheath/pulley and resulting in locking of thumb or finger in flexion/extension
- **etiology**: idiopathic or associated with RA, DM, hypothyroidism, gout, and pregnancy
- **clinical features**
  - ring finger is most commonly affected, then long finger and thumb
  - patient complains of catching, snapping, or locking of affected finger
  - tenderness to palpation/nodule at palmar aspect of MCP over A-1 pulley
  - women are 4 times more likely to be affected than men
- **non-surgical treatment**
  - NSAIDs
  - steroid injection; injections less likely to be successful in patients >60 yr, or symptoms greater than 6 mo
  - splint
- **surgical treatment**
  - indicated if no relief of symptoms or minimal relief with steroids
  - incise A-1 flexor pulley to permit unrestricted, full active finger motion

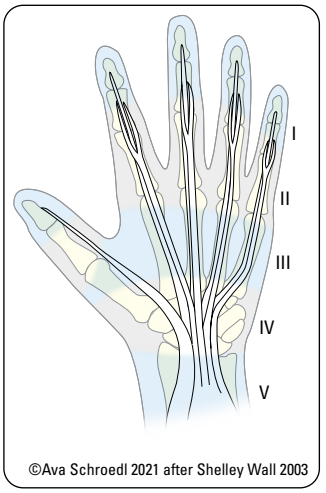

Figure 26. Zones of the flexor tendons

A-2 and A-4 pulleys are most important for function; prevent bowstringing of tendons

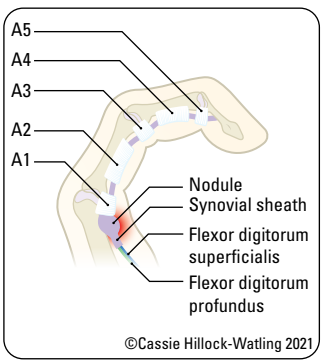

Figure 27. Digital flexor pulley system

Fractures and Dislocations

- for fracture principles, see Orthopaedic Surgery, OR5

FRACTURES
- about 90% of hand fractures are stable in flexion (splint to prevent extension)
- **position of safety**
  - wrist extension 0-30°
  - MCP flexion 70-90°
  - IP full extension
  - this is done if you want to immobilize a fracture but are not sure whether there are other injuries
- stiffness secondary to immobilization is the most important complication

Distal Phalanx Fractures
- most commonly fractured bone in the hand
- usual mechanism is crush injury, and thus accompanied by soft tissue injury
- subungual hematoma is common and must be decompressed, especially if there is involvement of >50% of the nail surface area, see *General Management of Hand Injuries (Categorized by Tissue)*, PL25
- treatment: 3 wk of digital splinting (immobilize the DIP with a STAX™ splint); if intra-articular fracture displaced >30%, then percutaneous pinning (K-wires) and splint, or ORIF

Proximal and Middle Phalanx Fractures
- check for: rotation, scissoring (overlap of fingers on making a fist), shortening of digit
- non-displaced or minimally displaced: closed reduction (if extra-articular), buddy tape to neighbouring stable digit, elevate hand, careful motion of extremity with splint to prevent reinjury, splinted for 2-3 wk
- displaced, non-reducible, not stable with closed reduction, or rotational or scissoring deformity: percutaneous pinning (K-wires) or ORIF, and splint

Metacarpal Fractures
- generally accept varying degrees of deviation before reduction required: up to 10° (D2), 20° (D3), 30° (D4), or 40° (D5)
- **Boxer's fracture**: acute angulation of the neck of the 5th metacarpal into palm
  - mechanism: blow on the distal-dorsal aspect of closed fist
  - loss of prominence of metacarpal head, volar displacement of head
  - up to 30-40° angulation may be acceptable
  - closed reduction should be considered to decrease the angle
  - if stable, ulnar gutter splint for 4-6 wk
- **Bennett's fracture**: two-piece fracture/dislocation of the base of the thumb metacarpal, usually intra-articular
  - unstable fracture
  - APL pulls MC shaft proximally and radially, causing adduction of thumb
  - treat with percutaneous pinning or ORIF, followed by thumb spica for 6 wk
- **Rolando fracture**: T- or Y-shaped fracture of the base of the thumb metacarpal
  - treated like a Bennett's fracture

DISLOCATIONS
- treatment: must be reduced as soon as possible
- dislocation vs. subluxation
  - dislocation: severe injury where articular surfaces of a joint are no longer in contact with one another
  - subluxation: articular surfaces of a joint are partially out of place (i.e. "partial dislocation" – often unstable and requires reduction)

PIP and DIP Dislocations (PIP more common than DIP)
- usually dorsal dislocation (commonly from hyperextension)
- 3 views of hand needed with x-ray imaging to assess degree of dislocation (posteroanterior, oblique, and lateral)
- if closed dislocation: closed reduction and splinting in position of function for 1 wk or buddy taping, and early mobilization (prolonged immobilization causes stiffness)
- open injuries are treated with wound care, irrigation, and debridement, followed by closed or open reduction and antibiotics

MCP Dislocations (relatively rare)
- dorsal dislocations much more common than volar dislocations
- dorsal dislocation of proximal phalanx on metacarpal head; most commonly index finger (hyperextension)
- two types of dorsal dislocation
  - simple (reducible with manipulation): treat with closed reduction and splinting for 2-4 wk at 60-70° MCP flexion
  - complex (irreducible – most commonly due to volar plate blocking the reduction): treat with open reduction

UCL Injury of the Hand
- forced abduction of thumb (e.g. ski pole injury)
- **skier's thumb**: acute UCL injury – if stable (elbow valgus stress test), treated with splint x 6-8 wk; if unstable, patient may have Stener lesion
- **Gamekeeper's thumb**: chronic UCL injury, often requires open repair and tendon graft for stabilization
- **Stener lesion**: the distal portion of the UCL can detach and flip superficial to the adductor aponeurosis and will not appropriately heal – requires open repair (requires x-ray imaging to diagnose)
- **evaluation**: radially deviate thumb MCP joint in full extension and at 30° flexion and compare with non-injured hand. UCL rupture is presumed if injured side deviates more than 30° in full extension or more than 15° in flexion

Dupuytren's Disease

Definition
- proliferative disorder of the palmar fascia, forming nodules (usually painless), fibrous cords, and flexion contractures at the MCP and interphalangeal joints
- flexor tendons not involved
- Dupuytren's diathesis: male sex, early age of onset, strong family history (autosomal dominant inheritance), involvement of multiple digits, bilateral involvement, and involvement of sites other than palmar aspect of hand, including the plantar fascia (Ledderhose's) and the penis (Peyronie's; see Urology, *Table 24*, U33)

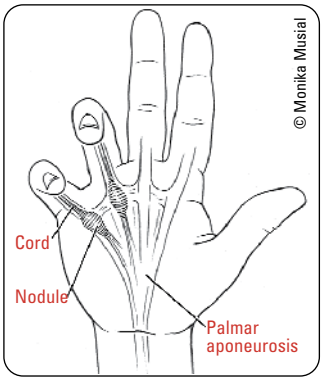

Figure 28. Dupuytren's disease

Epidemiology
- unusual in Asian patients or patients of African descent, high incidence in northern European patients, men > women, often presents in 5th-7th decade of life; associated with but not caused by alcohol use, smoking, and DM

Clinical Features
- nodules, cords, and contractures of MCP, PIP, and DIP
- order of digit involvement (most common to least common): ring > little > long > thumb > index
- risk of recurrence

Treatment
- palmar pit or nodule: no surgery (steroid injections for pain)
- palpable band/cord with no limitation of extension (i.e. no contracture) of either MCP or PIP: no surgery
- MCP contracture >30° or PIP contracture of any degree: needle aponeurotomy, collagenase *Clostridium histolyticum* (Xiaflex®) injection (indicated if cord is palpable), or surgical fasciectomy
- contractures impeding function and/or hygiene: needle aponeurotomy, collagenase injection, or surgical fasciectomy
- MCP joints have better outcomes than PIP joints post-treatment (achievement of near full extension, lower risk of recurrence)

Carpal Tunnel Syndrome

Definition
- median nerve compression at the level of the flexor retinaculum/transverse carpal ligament

Etiology
- median nerve entrapment at wrist
- primary cause is idiopathic
- secondary causes: space occupying lesions (tumours, hypertrophic synovial tissue, fracture callus, and osteophytes); metabolic and physiological (pregnancy, hypothyroidism, acromegaly, and RA); job/hobby-related repetitive trauma, especially forced wrist flexion

Epidemiology
- F:M=4:1, most common entrapment neuropathy

Clinical Features
- classically, patient awakened at night with numb/painful hand, relieved by shaking/dangling/rubbing
- on exam, sensory loss in median nerve distribution (see Figure 4, PL2), but thenar eminence sensory loss is spared (palmar cutaneous branch given off prior to carpal tunnel)
- decreased light touch and 2-point discrimination at DIP radial and ulnar creases; discriminative touch often lost first
- advanced cases: thenar wasting/weakness due to involvement of the motor branch of the median nerve
- ± Tinel's sign (paresthesia on percussion of nerve)
- ± Durkan's sign (paresthesia after pressure over carpal tunnel <30 seconds)
- ± Phalen's sign (wrist flexion induces symptoms)

Investigations
- generally a clinical diagnosis
- NCS and EMG studies may be used to objectively confirm the diagnosis if clinical history is atypical

Treatment
- avoid repetitive wrist and hand motion, wrist splints at night and when repetitive wrist motion required
- conservative: night-time splinting to keep wrist in neutral position
- medical: NSAIDs, local corticosteroids injection (relief from local corticosteroid injections is also diagnostic)
- surgical decompression: transverse carpal ligament incision to decompress median nerve
- indications for surgery: persistent signs and symptoms of median nerve compression not relieved by conservative management, or if motor function is compromised

Brachial Plexus

Etiology
- common causes of brachial plexus injury: complication of childbirth and trauma
- other causes of injury: compression from tumours, supernumerary ribs

Common Palsies

Table 22. Named Neonatal Palsies of the Brachial Plexus

Palsy	Location of Injury	Mechanism of Injury	Features
Duchenne-Erb Palsy	Upper brachial plexus (C5-C6)	Head/shoulder distraction (e.g. motorcycle)	"Waiter's tip deformity" (shoulder internal rotation, elbow extension and pronation, wrist flexion)
Klumpke's Palsy	Lower brachial plexus (C8-T1)	Traction on abducted arm	"Claw hand" May include Horner's syndrome

Differential Diagnosis of Adult-Acquired Brachial Plexus Palsies
- trauma (blunt, penetrating)
- thoracic outlet syndrome
  - associated with large cervical rib, anomalous first rib, strenuous arm work, and neck muscle hypertrophy
  - neurogenic: compression of brachial plexus, resulting in upper limb paresthesia, pain, and weakness
  - vascular: compression/thrombosis of subclavian artery/vein, resulting in pain; pallor and Raynaud's if arterial; swelling and cyanosis if venous
- tumour
  - schwannoma: well-defined margins enable total resection
  - neurofibromas: associated with neurofibromatosis type I
  - other: e.g. Pancoast syndrome (apical lung tumour)
- neuropathy (compressive, post-irradiation, viral, diabetic, idiopathic)

Investigations
- EMG
- MRI: gold standard for identifying soft tissue masses and nerve roots
- CT myelogram
- closed injuries: if avulsion suspected, then CT myelogram or MRI initially; otherwise, EMG/NCS 12 wk post-injury to assess healing progress
- open injuries: OR for exploration within a few days post-injury (once patient stable)

Management

Table 23. Management of Brachial Plexus Injuries*

Closed Injuries	Concussive/compressive	Often self-resolving (unless expanding mass, e.g. hematoma)
	Traction/stretch	If no continued insult, follow for 3-4 mo for improvement
	Obstetric palsy	Surgery if no significant improvement and/or residual paresis at age 6 mo
Open Injuries	Sharp or vascular injury	Explore immediately in OR

*All injuries listed require splinting as well as OT and PT consults to maintain ROM and function in the joint

Nerve Transfers
- indicated when nerve injury is close to the effector muscle or when other reconstructive options are not possible (e.g. preganglionic root avulsion, complete loss of motor, and/or sensory function); can also serve as adjunct to nerve grafting
- involves the use of an expendable nerve as a donor, such as one that supplies redundant innervation or one with less importance to daily functioning
- donor nerve serves to:
  - reconstruct the injured nerve closer to its effector muscle to better facilitate reinnervation, or
  - directly innervate effector muscle (neurotization)
- cortical plasticity involved in re-programming new nerve function
- can also serve as adjunct to nerve grafting
- both motor and sensory nerve transfers are possible, allowing motor and/or sensory restoration by neurotization
- three types of donors:
  - intraplexal (e.g. ulnar or median nerve fascicles)
  - extraplexal (e.g. contralateral C7 nerve root, intercostal nerve)
  - distal (e.g. radial nerve branches)

Craniofacial Injuries

- low velocity vs. high velocity injuries determine degree of damage
- fractures cause bruising, swelling, and tenderness ➔ loss of function
- management: most can wait ~5 d for swelling to decrease before ORIF required

Approach to Facial Injuries

- ATLS protocol
- inspect, palpate, clinical assessment for injury to underlying structures (e.g. facial nerve, bony injuries, septal hematoma, ocular involvement, etc.)
- tetanus prophylaxis
- radiological evaluation: CT scan with fine cuts of 1.5 mm through the orbit
- wound irrigation with NS/RL and remove foreign materials
- conservative debridement of detached or nonviable tissue
- repair laceration(s) at the time of presentation with 4-0 nylon sutures when the patient's general condition allows
- consider intracranial trauma; rule out skull fracture

Patients with major facial injuries are at risk of developing upper airway obstruction (displaced blood clots, teeth, or fracture fragments; swelling of pharynx and larynx; loss of support of hyomandibular complex ➔ retroposition of tongue); also at risk of ocular injury

Investigations

- CT (gold standard)
  - axial and coronal (specifically request 1.5 mm cuts): for fractures of upper, middle, and lower face
  - indicated for significant head trauma, suspected facial fractures, and preoperative assessment
- panorex radiograph: shows entire upper and lower jaw; best for isolated mandible fracture, but patient must be able to sit; however, if high clinical suspicion and negative panorex, CT should be done

Signs of Basal Skull Fracture
- Battle's sign (bruised mastoid process)
- Hemotympanum
- Raccoon eyes (periorbital bruising)
- CSF otorrhea/rhinorrhea

Treatment Goals

- re-establish normal occlusion if occlusion is an issue
- normal eye function (extraocular eye movements and visual acuity)
- re-establish facial height and width to re-establish appearance
- consultation when indicated (dentistry, ophthalmology, neurosurgery)

Mandibular Fractures

- two points of injury since it is a ring structure (includes fractures and dislocations)
- commonly at sites of weakness (condylar neck, angle of mandible)

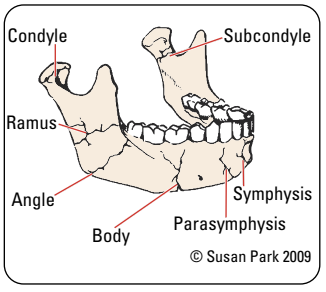

Figure 29. Mandibular fracture sites

Etiology

- anterior force: bilateral fractures
- lateral force: ipsilateral subcondylar and contralateral angle or body fracture
- note: classified as open if fracture into tooth bearing area (alveolus)

Clinical Features

- pain, swelling, difficulty opening mouth ("trismus")
- malocclusion, asymmetry of dental arch
- damaged, loose, or lost teeth
- palpable "step" along mandible
- numbness in CN V3 distribution
- intra-oral lacerations or hematoma (sublingual)
- chin deviating toward side of a fractured condyle

Classification

Table 24. Mandibular Fracture Classifications by Anatomic Region

	Areas/Boundaries
Symphysis	Midline of the mandible; between the central incisors from the alveolar process through the inferior border of the mandible
Body	From the symphysis to the distal alveolar border of the third molar
Angle	Triangular region between the anterior border of the masseter and the posterosuperior insertion of the masseter distal to the third molar
Ramus	Part of the mandible that extends posterosuperiorly into the condylar and coronoid processes
Condylar*	Area of condylar process of mandible
Subcondylar	Area below the condylar neck (i.e. sigmoid notch) of the mandible
Coronoid Process	Area of the coronoid process of mandible

*Most common mandibular fracture type

Treatment
- maxillary and mandibular arch bars wired together (intermaxillary fixation) or ORIF (indications depend on whether fracture is unilateral/bilateral, etc.); ideally managed within 48 h
- antibiotics from initial presentation until at least 3 doses postoperatively; if late presentation, may consider treatment with antibiotics for an extended course

Maxillary Fractures

Table 25. Le Fort Classification

	Le Fort I	Le Fort II	Le Fort III
Alternative Name	Guérin fracture	Pyramidal fracture	Craniofacial disjunction
Type of Fracture	Horizontal	Pyramidal	Transverse
Structures Involved	Piriform aperture	Nasal bones	Nasofrontal suture
	Maxillary sinus	Medial orbital wall	Zygomaticofrontal suture
	Pterygoid plates	Pterygoid plates	Pterygoid plates
		Maxilla	Zygomatic arch
Anatomical Result	Maxilla divided into 2 segments	Maxillary teeth and midsection of the maxilla separated from upper face	Entire midfacial skeleton detached from cranial base

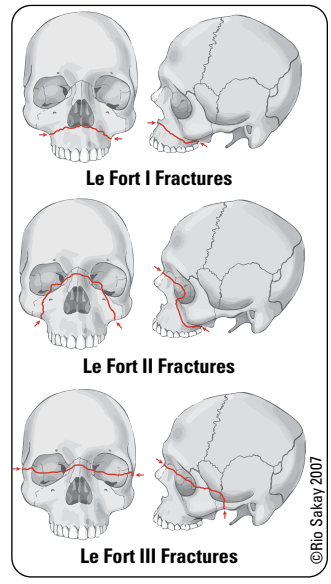

Figure 30. Le Fort fractures

Nasal Fractures

Etiology
- lateral force → more common
- anterior force → can produce more serious injuries
- most common facial fracture

Clinical Features
- epistaxis/hemorrhage, deviation/flattening of nose, swelling, periorbital ecchymosis, tenderness over nasal dorsum, crepitus, septal hematoma, respiratory obstruction, subconjunctival hemorrhage

Treatment
- treated for airway or cosmetic issues
- always inspect for, and drain, septal hematoma as this is a potential cause of septal necrosis and perforation – completed with small incision in the septal mucosa followed by packing
- closed reduction with Asch or Walsham forceps under anesthesia, pack nostrils with petroleum or non-adhesive gauze packing, nasal splint for 7 d
- best reduction immediately (<6 h) or when swelling subsides (5-7 d)
- rhinoplasty may be necessary later for residual deformity (30%)

Zygomatic Fractures

Classification
1. fracture restricted to zygomatic arch
2. depressed fracture of zygomatic complex (zygoma)
3. unstable fracture of zygomatic complex (tetrapod fracture) – separations occur at maxilla, frontal bone, temporal bone, and orbital rim

Clinical Features
- 3 most common features (pathognomonic):
  - subconjunctival hemorrhage
  - periorbital ecchymosis (often associated with fractures of the orbital floor)
  - CN V2 numbness (infraorbital and superior dental nerves)
- flattening of malar prominence (view from above)
- pain over fractures on palpation
- palpable step deformity in bony orbital rim (especially inferiorly)
- ipsilateral epistaxis; trismus
- ophthalmologic evaluation if suspected globe injury

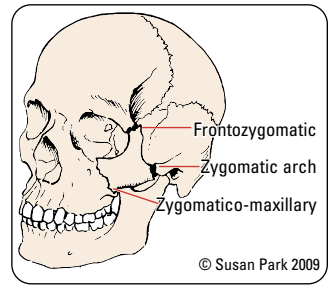

Figure 31. Zygomatic fractures

Treatment
- if non-displaced, stable, and no symptoms, then soft diet; no treatment necessary
- non-displaced zygomatic arch fractures can be elevated using Gillies approach (leverage on the anterior part of the zygomatic arch via a temporal incision) or Keane approach (elevation through upper buccal sulcus incision) only if arch is not comminuted
- if arch is comminuted, coronal incision and ORIF is required
- ORIF for displaced or unstable fractures of zygomatic complex (route is dependent on location of fracture)

Orbital Floor Fractures

- see Ophthalmology, OP42

Definition
- fracture of floor of orbit: may be a "pure blow-out fracture," which has an intact orbital rim, or can be associated with other fractures (orbital rim fracture and/or zygoma)

Etiology
- blunt force to eyeball (e.g. baseball or fist) ➔ sudden increase in intraorbital pressure

Clinical Features
- restricted EOM (if muscle trapped)
- periorbital edema and bruising, subconjunctival hemorrhage
- ptosis, exophthalmos, exorbitism, enophthalmos, and hypoglobus may be present
- diplopia may be present
- orbital rim step-offs with possible infraorbital nerve anesthesia
- orbital entrapment
  - clinical diagnosis that is a surgical emergency
  - diplopia with straight gaze: unable to look up past neutral (entrapment of inferior rectus), limited EOM
  - severe pain or N/V with upward globe movement

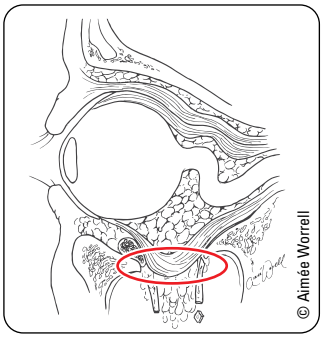

Figure 32. Blow-out fracture

Investigations
- CT (diagnostic): axial, coronal, and sagittal views – with fine cuts through orbit; rounding of inferior rectus can be a sign of orbital entrapment
- diagnostic maneuver for entrapment is forced duction test (pulling on inferior rectus muscle with forceps to ensure full ROM) under general anesthesia in the OR

Treatment
- surgical repair indicated if: entrapment, any size defect with enophthalmos (if patient is bothered by it), or persistent diplopia (>10 d)
- reconstruction of orbital floor with bone graft or alloplastic material (e.g. titanium meshes, MEDPOR®, MEDPOR TITAN®)
- after repair, many patients can have diplopia for several weeks

Complications
- persistent diplopia
- enophthalmos

Superior Orbital Fissure Syndrome
- fracture of SOF causing ptosis, proptosis, anesthesia in CN V1 distribution, and painful ophthalmoplegia (paralysis of CN III, IV, VI)
- uncommon complication seen in Le Fort II and III fractures (1/130)
- recovery time reported as 4.8-23 wk following operative reduction of fractures

Orbital Apex Syndrome
- fracture through optic canal with involvement of CN II at apex of orbit
- symptoms are the same as SOF syndrome plus vision loss
- treatment is steroids or urgent decompression of fracture in optic canal (posterior craniotomy for decompression)

Traumatic Auricular Hematoma (Cauliflower Ear)

Definition
- trauma to the auricle that creates a subperichondrial hematoma that, if not corrected quickly, will form a permanent disfiguring nodularity known as "cauliflower ear"

Epidemiology
• higher prevalence in athletes who participate in contact risk sports (e.g. mixed martial arts, boxing), however it is not exclusive to athletes

Clinical Features
- painless or slightly tender swelling of the upper aspect of the pinna
- becomes firmer and harder with time if left untreated
- colour is skin-coloured or slightly bluish

Differential Diagnosis
- relapsing polychondritis, auricular pseudocyst, epidermoid cyst

Treatment

- aspiration, incision and drainage, and splinting of the auricular hematoma within 7 d (preferably first 72 h)

Breast

Anatomy

Vascular Supply

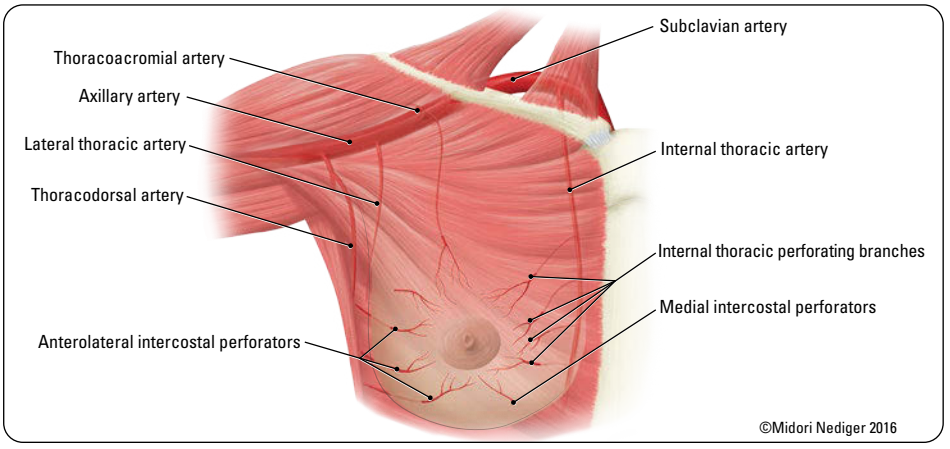

Figure 33. Breast vasculature

Innervation

- innervated in a dermatomal pattern from branches of the thoracic intercostal nerves (T3-6)
  - medially innervated from anterior cutaneous branches of I-VI intercostal nerves
  - laterally innervated from lateral cutaneous nerve branches of II-VII intercostal nerves
- lateral and upper portions of the breast innervated by lower fibres of the cervical plexus (C3, C4)
- NAC
  - supplied by anterior and lateral cutaneous branches of intercostal nerve IV
  - additional innervation by cutaneous branches of intercostal nerves III and VI

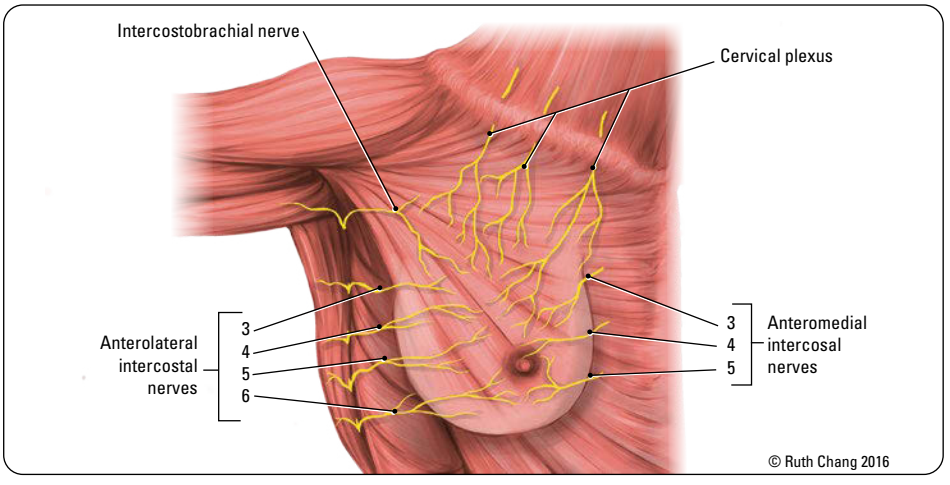

Figure 34. Innervation of the breast

Breast Reduction

Indications

- symptomatic (general symptoms)
  - musculoskeletal pain (back, bra strap location, neck), chronic headache, paresthesia in upper limb, rashes/irritation under the breast, breast discomfort, and physical impairment
- breast reduction methods can be classified based on pedicle (i.e. blood supply to the NAC) and skin resection pattern (i.e. the resultant scar)

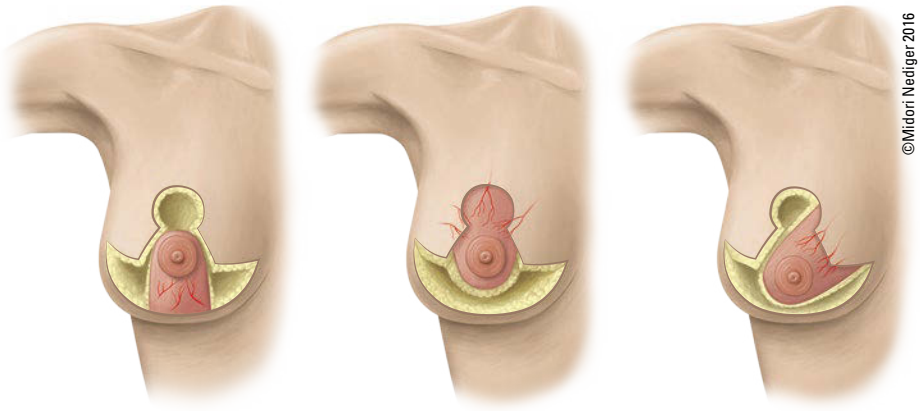

Figure 35. Inverted T ("Wise") pattern reduction

Common Types of Pedicles

- inferior pedicle: derived from the fourth, fifth, and sixth intercostal perforators; most commonly used with the inverted T ("Wise") pattern reduction; versatile in small-large breast reduction
  - recommended pedicle width 6-8 cm, 8-10 cm in large breasts
- superior pedicle: derived from the internal mammary perforator of the second intercostal space
- medial pedicle: blood supplied by internal mammary perforators from third intercostal space, and may have contribution from fourth intercostal space
- superomedial pedicle: incorporates the descending artery from the second intercostal space as the medial pedicle base extends superolaterally to the breast meridian
- bipedicle: used in McKissock's technique (well-vascularized dermal-parenchymal vertical bipedicle)

Table 26. Type of Skin Resections/Scar Options

	Indications	Description
Inverted T Pattern	Large breasts	Commonly used in association with inferior pedicle
	Breasts with poor quality skin that are challenging to remodel	Large portion of skin removed in horizontal and vertical direction
		Skin integrity important to shape and hold breast parenchyma
Vertical Pattern	Surgeon preference	Used in association with superior or medial pedicle
		Parenchyma needed to shape skin
		No horizontal scar

Complications

- NAC necrosis
- sensory alteration of nipple (may vary with type of pedicle) (may increase or decrease)
- unsatisfactory scarring, including hypertrophic or keloid scar
- wound healing complications (1-5% in healthy patients, higher in patients with elevated BMI)
- hematoma
- wound infection
- fat necrosis
- asymmetry of breasts and NAC
- potential inability to breastfeed

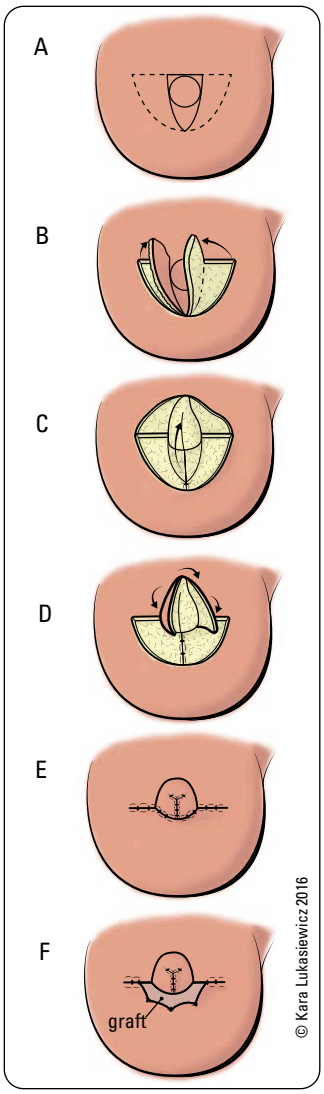

Figure 36. Skate flap
A) incision outline
B) elevation of wings
C) elevation of entire flap
D) caudal folding of flap
E) skate flap with primary closure of donor site
F) with skin graft

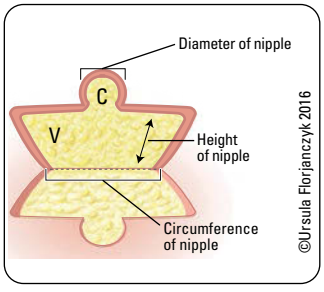

Figure 37. C-V flap

Mastopexy (Breast Lift)

Definition
- aesthetic procedure of the breast used to correct breast ptosis by modifying the contour and size of the breast along with elevating the position of the nipple

Clinical Grading of Ptosis (Regnault Ptosis Grade Scale)
1. minor ptosis (Grade 1)
   - nipple at inframammary fold
2. moderate ptosis (Grade 2)
   - nipple below inframammary fold, but above lower breast contour
3. severe ptosis (Grade 3)
   - nipple below inframammary fold and at lower breast contour
4. glandular ptosis/pseudoptosis
   - ptosis of the lower pole of the breast where the NAC is at or above the inframammary fold

Choice of Incision
- mastopexy can be performed through the same incisions as breast reductions

Breast Augmentation

Definition
- procedure designed to increase the size of the breast

Choice of Incision
- position of incision individualized since no single incision is best for all patients
- 3 commonly used types of incision: periareolar, inframammary crease, transaxillary

Type of Implant
- silicone or saline-filled
- subclassified into various styles of surface and shape

Location of Implant
- implants are commonly placed in the following positions:
  1. submuscular
     - implant placed deep to the pectoralis major muscle
     - most commonly in patients that do not have enough tissue to cover the implant
  2. subglandular
     - implant placed deep to glandular breast tissue but superficial to muscle
  3. subfascial
     - implant placed below the pectoralis fascia

Complications
- hematoma, infection, capsular contracture, leakage rupture, aesthetic deformity
- breast implant illness
- BIA-ALCL
  - increased risk of BIA-ALCL with textured implants
  - presents as sudden onset of pain without injury, or as sudden onset of seroma on average 7-8 yr after use of a textured implant for reconstruction or augmentation purposes
  - etiology: several theories, including implant-induced chronic inflammation, chronic biofilm, reaction to silicone shards, and causes not yet determined
  - risk estimated by Health Canada to be 1/3565 for Allergan Biocell® macro-textured implants and 1/16703 for Mentor® Siltex® micro-textured implants (Health Canada safety alert RA-70045)
  - management: en bloc resection of the implant and capsule; standard secondary therapy includes brentuximab
- favourable clinical outcome if detected and treated early

Gynecomastia

Definition
- benign enlargement of the male breast due to proliferation of the glandular tissue

Clinical Classification
- gynecomastia can be further classified into:
  1. idiopathic
  2. physiologic
     - neonatal: circulating maternal estrogens via placenta
     - pubertal: relative excess of plasma estradiol vs. testosterone
     - elderly: decreased circulating testosterone, peripheral aromatization of testosterone to estrogen
  3. pathologic
     - endocrinopathies: excess estrogen, androgen deficiency, deficient testosterone production or action
     - tumours
     - chronic disease: liver cirrhosis, renal
     - congenital/genetic: Klinefelter's syndrome, androgen resistance
  4. pharmacologic
     - drugs that may interfere with estrogen-testosterone balance including:
       - hormones (estrogens, gonadotropins, exogenous steroids)
       - antiandrogens

       androgen receptor antagonists (steroidal and non-steroidal)
       androgen synthesis inhibitors (5α-reductase inhibitors)
       antigonadotropins (GnRH analogs, estrogens)
       - recreational drugs (cannabis, heroin, amphetamines)
       - antihypertensives (spironolactone)
  5. massive weight gain
- for physical exam, investigations, and medical management (see Endocrinology, E55)

Surgical Options
- surgery is the accepted method of management for gynecomastia
- surgery addresses the three components: breast tissue, fat, skin
- often involves a combination of liposuction (to remove the fatty portion) and surgical excision through a small periareolar incision (to remove the glandular component)
- patients with significant skin excess may require skin excision as well

Breast Reconstruction

- use of alloplastic devices or autogenous tissue to reconstruct breast after cancer or trauma
- reconstruction can be performed immediately (at the same time as mastectomy) or delayed (as a separate surgery months or years after initial surgery)
- there are alloplastic and autogenous methods of reconstruction, each with its advantages and disadvantages

Table 27. Timing of Immediate Reconstruction vs. Delayed Reconstruction

	Advantages	Disadvantages
Immediate Reconstruction	Generally best aesthetic outcome; may preserve nipple if oncologically safe Does not require creation of additional skin Tissues are not damaged from scarring	Mastectomy flap viability can compromise outcome Longer surgical time
Delayed Reconstruction	Good option for patients unable to have immediate reconstruction For patients who may be getting radiotherapy and undetermined post-surgery oncologic treatment Provides option of contralateral surgery with reconstruction, if required (i.e. contralateral cancer, genetic marker for disease)	Loss of skin, volume, lateral border of breast, and natural landmarks, including inframammary fold (makes surgery more challenging) Resection of irradiated/scarred skin and associated wound healing complications, including risk of reconstructive failure Likely requires more stages than immediate reconstruction for completion

Table 28. Alloplastic Reconstruction vs. Autogenous Reconstruction

		Advantages	Disadvantages
Alloplastic Reconstruction	Single stage direct to implant (DTI)	Shorter surgery May give a more complete or final result	Size restriction in reconstruction Very few women meet criteria: Grade 1 ptosis, small breast, skin-sparing mastectomy
	Two stage reconstruction with expander and implant	Less tension on mastectomy flaps compared to single-stage reconstruction with implants Ability to increase amount of skin and avoid use of flap Some patient control over final outcome	Requires multiple OR procedures and clinic visits Waiting time between first and second stages Requires post-surgical procedures (patient to come to clinic for inflations) Size of reconstruction limited to mastectomy flap size and vascularity
	Acellular dermal matrix and implant	Can cover areas of implant or tissue expander and place it above muscle (no muscle dissection required) Can create larger submuscular pocket for bigger device	Animation if submuscular
Autogenous Reconstruction	Latissimus dorsi flap	Reliable pedicle Uses patient's own tissues Provides skin and muscle Possible to do muscle sparing procedure without flap compromise Provides good amount of skin and muscle for reconstruction Good option for delayed reconstruction, larger women, previously failed reconstruction, radiated breasts, and to avoid complications of using abdominal wall	May also require implants for adequate volume
	Transverse Rectus Abdominis Myocutaneous (TRAM) flap	Can be done as a: Pedicled TRAM Free tissue transfer (Free TRAM) Patient's own tissue	Abdominal scarring and second wound Volume depends on patient's donor site
		Provides a good amount of tissue for transfer in most women Provides a well-concealed scar	Pedicled TRAM: Weakness in rectus abdominis with higher bulge rates Free TRAM: Similar complications to DIEPs Less muscle used than pedicled TRAM, decreased risk of hernia or bulge
	DIEP	Method spares rectus abdominis muscle and fascia and should theoretically preserve innervation and continuity of abdominal wall	May not always be possible Abdominal scarring and second wound

Nipple Areolar Complex Reconstruction

- nipple reconstruction is usually done as the final step when the patient is satisfied with breast mound creation
- reconstruction can be performed with local anesthetic since many women have decreased sensation in the mastectomy or breast flaps
- it can be done by either a flap, graft, or 3D tattoo

Table 29. Types of Nipple Reconstruction

	Description	Advantages	Disadvantages
Skate Flap	Pedicle elevated above breast mound Lateral aspects of flap are wrapped around central aspect of flap Defect mainly closed by skin graft	Low complication rates	Loss of projection Donor site morbidity May have loss of projection over time Skin graft required
C-V Flap	Utilizes C flap and two V flaps for nipple reconstruction Diameter of C flap becomes diameter of reconstructed nipple Width of V flaps dictate projection of reconstructed nipple C-V flap closed with primary closure	No grafts required	Loss of projection Nipple size limited by flap dimensions May have loss of projection over time Tattooing required to match natural areola
Nipple Graft	Tissue commonly from contralateral nipple (nipple share) or labia Two methods for nipple graft: • Distal aspect of nipple removed transversely and defect closed with purse string suture • Nipple divided in half longitudinally, folded over, and closed with primary closure	Nipple share is an excellent option in patients with contralateral nipple projection >1 cm	Loss of projection Donor site morbidity Decreased contralateral nipple sensation Necrosis of graft or donor nipple

Table 30. Types of Areolar Reconstruction

	Description	Advantages	Disadvantages
Tattoo*	Conducted 3-4 mo after nipple reconstruction when most of the projection has stabilized	Can provide more accurate colour matching with limited morbidity	May require touch-ups due to pigment fading over time with skin sloughing
Skin Graft*	Full thickness skin grafts, commonly from inner aspect of thigh or opposite areola	Provides texture and pigment resembling a natural areola	Donor site morbidity

* Tattoo and skin grafting can be used in conjunction

Aesthetic Surgery

Aesthetic Procedures

Table 31. Aesthetic Procedures

Location	Procedure	Description
Head/Neck	Hair transplants	Aesthetic improvement of hair growth patterns using hair follicle grafts or flaps
	Otoplasty	Surgical reconstruction of external ear
	Forehead/brow lift	Surgical procedure to lift the forehead and eyebrows
	Rhytidectomy	Surgical procedure to reduce wrinkling and sagging of the face and neck; "face lift"
	Blepharoplasty	Surgical procedure to shape or modify the appearance of eyelids by removing excess eyelid skin ± fat pads
	Rhinoplasty	Surgical reconstruction of the nose ± nasal airway
	Genioplasty	Chin augmentation via osteotomy or synthetic implant to improve contour
Skin	Chemical peel	Application of one or more exfoliating agents to the skin resulting in destruction of portions of the epidermis and/or dermis with subsequent tissue regeneration
	Dermabrasion	Skin resurfacing with a rapidly rotating abrasive tool; often used to reduce scars, irregular skin surfaces, and fine lines
	Laser resurfacing	Application of laser to the skin which ultimately results in collagen reconfiguration and subsequent skin shrinking and tightening; often used to reduce scars and wrinkles
	Injectable fillers	An injectable substance is used to decrease facial rhytids; can augment lips to create fuller appearance; substances include: collagen, fat, hyaluronic acid, and calcium hydroxyapatite (most common substances include hyaluronic acid and fat)
Other	Abdominoplasty	Removal of excess skin and repair of rectus muscle laxity (rectus diastasis); "tummy tuck"
	Calf augmentation	Augmentation of calf muscle with implants
	Liposuction	Surgical removal of adipose tissue for body contouring (not a weight loss procedure)

Gender-Affirming Surgery (Transition-Related Surgery)

- ensure appropriate use of gender pronouns
- some procedures require 1 yr trial of hormone therapy, preoperative letters of evaluation and documentation from mental health professionals as outlined by the World Professional Association for Transgender Health Standards of Care – Version 7 guidelines

Table 32. Surgical Options for Transgender Women

Procedure	Description	Follow-Up
Breast Augmentation	Implant-based, fat-grafting, or combined surgery to increase breast size	Surveillance for implant rupture Adhere to breast cancer screening guidelines in addition to gender-specific medical maintenance
Contouring Procedures	Altering fat distribution in distinguishing regions of the body (abdomen, flank, hip, and buttock) using liposuction or fat-grafting (limited by availability of autologous fat)	Short-term restrictions on placing body weight on fat-grafted areas (<2 wk) 100% of injected fat volume not maintained long-term
Facial Feminization	± Hairline surgery ± Forehead augmentation or osteotomy ± Rhinoplasty ± Genioplasty (implant alone is usually not sufficient)	Hair transplant may be needed in adjunct May have altered lip sensation and altered sensation of lower incisors with genioplasty
Chondrolaryngoplasty	Cartilage removal to reduce thyroid cartilage size	Risk of long-term hoarseness based on anatomical proximity of recurrent laryngeal nerve to site of surgery
Vocal Cord Surgery	Alteration of vocal cord length to increase vocal pitch	Not all procedures are permanent (i.e. cricothyroid approximation) Some procedures may narrow airway (i.e. anterior glottal web formation) Not guaranteed to achieve exact desired pitch change
Vaginoplasty	see Urology, *Transition-Related Surgeries*, Table 26, U47	

Table 33. Surgical Options for Transgender Men

Procedure	Description	Follow-Up
Chest Masculinization	Most common technique is double incision free nipple graft technique	Loss of nipple sensation May need liposuction for patients with excess subcutaneous tissue
Contouring Procedures	see Table 32	
Facial Masculinization	± Forehead augmentation ± Maxillary augmentation ± Mandibular augmentation ± Rhinoplasty ± Genioplasty	May have altered lip sensation and altered sensation of lower incisors with genioplasty
Thyroid Cartilage Enhancement	Cartilage added to increase thyroid cartilage prominence	Risk of vocal cord paralysis due to surgery
Vocal Cord Surgery	Alteration of vocal cord length to decrease vocal pitch	Not guaranteed to achieve exact desired pitch change
Phalloplasty, Metoidioplasty	see Urology, *Transition-Related Surgeries*, Table 26, U47	

- for further information on gender-affirming surgical techniques, see Urology, *Transition-Related Surgeries*, U47

Paediatric Plastic Surgery

Craniofacial Anomalies

Table 34. Paediatric Craniofacial Anomalies

	Definition	Epidemiology	Clinical Features	Treatment
Cleft Lip	Failure of fusion of maxillary and medial nasal processes	1 in 1000 live births (increased incidence in Asian individuals, decreased incidence in individuals of African descent) M:F=2:1	Classified as incomplete/complete and unilateral/bilateral; 2/3 cases: unilateral, left-sided, male	Surgery (3 mo): Millard, or Fisher (additional corrective surgeries usually required later on - especially for nasal deformity
Cleft Palate	Failure of fusion of lateral palatine/median palatine processes and nasal septum	Isolated cleft palate: 0.5 in 1000 (no racial variation) F>M 4% chance of cleft if one parent or sibling have cleft 17% chance of cleft if both sibling and parent have cleft	Classified as incomplete/complete and unilateral/bilateral Isolated (common in females) or in conjunction with cleft lip (common in males)	Special bottles for feeding SLP Surgery (6-9 mo): Von Langenbeck or Furlow Z-Plasty ENT consult – often recurrent otitis media, requiring myringotomy tubes
Craniosynostosis	Premature fusion of ≥1 cranial sutures	1 in 2000 live newborns; M:F=52:48 Syndromes include: Crouzon's, Apert's, Saethre-Chotzen, Carpenter's, Pfeiffer's, Jackson-Weiss, and Boston-type syndromes	Primary (no known cause), or secondary (associated with a known cause or syndrome)	Multidisciplinary team (including neurosurgery, ENT, genetics, dentistry, paediatrics, SLP) The type, timing, and procedure are dependent on which sutures (lambdoid, sagittal, etc.) are involved Early surgery prevents secondary deformities ↑ICP is an indication for emergent surgery

Congenital Hand Anomalies

Table 35. American Society for Surgery of the Hand (ASSH) Classification of Congenital Hand Anomalies

Classification	Example	Features	Treatment
Failure of Formation	Transverse absence (congenital amputation)	At any level (often below elbow/wrist)	Early prosthesis
	Longitudinal absence (phocomelia)	Absent humerus Thalidomide association	
	Radial deficiency (radial club hand)	Radial deviation Thumb hypoplasia M>F	Physiotherapy + splinting Soft tissue release if splinting fails Distraction osteogenesis (Ilizarov distraction) ± wedge osteotomy Tendon transfer Pollicization
	Thumb hypoplasia	Degree ranges from small thumb with all components to complete absence	Depends on degree – may involve no treatment, webspace deepening, tendon transfer, or pollicization of index finger
	Ulnar club hand	Rare, compared to radial club hand Stable wrist	Splinting and soft tissue stretching therapies Soft tissue release (if above fails) Correction of angulation (Ilizarov distraction)
	Cleft hand	Autosomal dominant Often functionally normal (depending on degree)	First web space syndactyly release Osteotomy/tendon transfer of thumb (if hypoplastic)
Failure of Differentiation/ Separation	Syndactyly	Fusion of ≥2 digits 1 in 3000 live births M:F=2:1 Classified as partial/complete Simple (skin only) vs. complex (osseous or cartilaginous bridges)	Surgical separation before 6-12 mo of age May require a skin graft to cover the fingers Usually good result
	Symbrachydactyly	Short fingers with short nails at fingertips	Digital separation Webspace deepening
	Camptodactyly	Congenital flexion contracture (usually at PIP, especially 5th digit)	Early splinting Volar release Arthroplasty (rarely)
	Clinodactyly	Radial or ulnar deviation Often middle phalanx	None (usually); if severe, osteotomy with grafting

Table 35. American Society for Surgery of the Hand (ASSH) Classification of Congenital Hand Anomalies

Classification	Example	Features	Treatment
Duplication	Polydactyly	Congenital duplication of digits May be radial (increased in Asian individuals and Indigenous peoples) or central or ulnar (increased in individuals of African descent)	Amputation of least functional digit Usually >1 yr of age (when functional status can be assessed)
Overgrowth	Macrodactyly	Rare	None (if mild) Soft tissue/bony reduction
Undergrowth	Brachydactyly	Short phalanges	Removal of nonfunctional stumps Osteotomies/tendon transfers Distraction osteogenesis Phalangeal/free toe transfer
	Symbrachydactyly Brachysyndactyly	Short webbed fingers	As above + syndactyly release
Constriction Band Syndrome	i.e. amniotic (annular) band syndrome	Variety of presentations	Urgent release for acute, progressive edema distal to band in newborn Other reconstruction is case specific
Generalized Skeletal Abnormality	Achondroplasia, Marfan syndrome, Madelung's deformity	Variety of presentations	Treatment depends on etiology

Acronyms

5-HT	serotonin	ECT	electroconvulsive therapy	MSE	mental status examination	SGA	second generation antipsychotics
ACh	acetylcholine	EPS	extrapyramidal symptoms	MST	magnetic stimulation therapy	SIADH	syndrome of inappropriate antidiuretic hormone secretion
ACT	assertive community treatment	ERP	exposure with response prevention	MZ	monozygotic	SNRI	serotonin and norepinephrine reuptake inhibitors
ADHD	attention deficit hyperactivity disorder	GAD	generalized anxiety disorder	NA	Narcotics Anonymous	SS	serotonin syndrome
ADL	activities of daily living	GMC	general medical condition	NMS	neuroleptic malignant syndrome	SSRI	selective serotonin reuptake inhibitor
AN	anorexia nervosa	IPT	interpersonal therapy	NOS	not otherwise specified	TCA	tricyclic antidepressant
ASD	autism spectrum disorder	IADL	instructional activities of daily living	OCD	obsessive-compulsive disorder	TD	tardive dyskinesia
ASPD	antisocial personality disorder	MBCT	mindfulness-based cognitive therapy	OCP	oral contraceptive pill	XR	extended-release
BN	bulimia nervosa	MBSR	mindfulness-based stress reduction	OCPD	obsessive-compulsive personality disorder		
CBT	cognitive behavioural therapy	MDD	major depressive disorder	ODD	oppositional defiant disorder		
CD	conduct disorder	MDE	major depressive episode	PCP	phencyclidine		
CRA	community reinforcement approach	MET	motivational enhancement therapy	PD	personality disorder		
CTO	community treatment order	MI	motivational interviewing	PDD	pervasive developmental disorder		
DA	dopamine			PTSD	post-traumatic stress disorder		
DBT	dialectical behavioural therapy			rTMS	repetitive transcranial magnetic stimulation		
DZ	dizygotic						

Psychiatric Assessment

History

Introduction
- name, role, purpose, circumstances (i.e. approximate time)
- limits of confidentiality (i.e. safety of dependents, harm to self or others)

Identifying Data
- necessary: name, age, gender (preferred pronouns), living situation (accommodation, independently, or with others), marital/relationship status, children, source of income/support, or occupation
- adjunct: outpatient/inpatient, referral source, known/unknown to provider

Chief Complaint
- in patient's own words, with duration of symptoms

History of Present Illness
- context: events, problems, stressors, losses, changes
- symptoms: onset, duration, intensity, progression, fluctuation with day/season
- impact on functioning: social, occupational, ADL/IADLs, personal care/survival
- coping strategies, treatments, personal/professional supports
- reason for seeking help that specific day
- prior episodes/experiences, longitudinal course (duration/frequency)
- last period of wellness, changes to usual personality when unwell
- opinions about cause/nature of concerns, willingness to engage, hopes/expectations of treatment

Screening Questions for Major Psychiatric Disorders
- Have you been feeling down, depressed, or hopeless?
- Do you feel anxious or worry about things?
- Has there been a time in your life where you have felt euphoric, extremely talkative, had a lot of energy, and a decreased need for sleep?
- Do you see or hear things that you think other people cannot?
- Have you ever thought of harming yourself or killing yourself?

Psychiatric Functional Inquiry
- mood: depression, mania
- other: trauma, obsessions/compulsions, disordered eating, active medical problems
- anxiety: worries, panic attacks, phobias, or social anxiety
- psychosis: hallucinations, delusions
- safety/risk: self (suicidal ideation/intent/plan (see *Suicide*, PS5), self-harm, neglect), others (homicide, aggression, violence), dependents (children, elderly, disabled, pets), driving, cooking/fires

Psychiatric Functional Inquiry

MOAPS
Mood
Other (medical problems and substance use)
Anxiety
Psychosis
Safety

Past Psychiatric History
- previous psychiatric diagnoses and mental health contacts
- hospitalizations: approximate total, date of last discharge
- emergency department visits (for mental health crisis)
- suicide attempts: number, severity, medical intervention, most recent
- self-harming behaviour (cutting)
- aggression/violence, legal (charges)
- treatments: pharmacological and non-pharmacological (effectiveness, side effects)

Substance Use History
- type: tobacco, cannabis, alcohol, other (stimulants, hallucinogens, prescription drugs, gambling/online)
- use: first, typical, last, periods of abstinence
- withdrawal symptoms (i.e. seizures, delirium tremens)
- previous treatments: counselling, detox, groups
- impact on symptoms, motivation to change

Past Medical/Surgical History
- all medical, surgical, neurological (i.e. head trauma, seizures) conditions/illnesses
- allergies

Medications
- names, doses, frequency
- adherence, effectiveness, side effects
- over the counter, supplements

Family Psychiatric/Medical History
- diagnoses, treatments, hospitalizations, suicide attempts, substance use, legal
- perceptions regarding mental illness, engagement with treatments
- if relevant: any past medical or genetic illness

Always Remember to Ask About Abuse
See Family Medicine, FM30

Past Personal/Developmental History (as relevant)
- birthplace, immigration history (if applicable), ethnicity/nationality, religion/spirituality
- family members: ages, occupations, personalities, quality of relationships
- history of verbal, physical, or sexual abuse
- prenatal and perinatal history: desired vs. unplanned pregnancy, maternal and fetal health, domestic violence, maternal substance use and exposures, complications of pregnancy/delivery
- early childhood to age 3: developmental milestones, temperament, family stability, primary caregivers/attachment figures
- middle childhood to age 11: school performance, peer relationships, bullying, activity/attention level, behavioural challenges
- late childhood to adolescence: school performance, drugs/alcohol, legal problems, peer and family relationships, extra-curriculars
- sexuality: puberty, gender identity, sexual orientation, sexual functioning/experiences, romantic relationships
- adulthood: education, employment, relationships
- hobbies, interests, sources of meaning, strengths, accomplishments, aspirations, hopes

Collateral History
- source, details provided

Mental Status Exam

General Appearance
- age (chronological vs. apparent), gender, ethnicity
- posture, grooming, hygiene, manner of dress, body habitus, distinguishing features
- eye contact, facial expression, alertness
- attitude: polite, friendly, collaborative, uncooperative, guarded/suspicious, evasive, agitated, aggressive/hostile
- reliability (consistency, congruent with collateral), ease of building rapport
- gait, psychomotor changes (slowing/agitation), tics, tremors, tardive dyskinesia, dystonia, catatonia

Mental Status Exam

ASEPTIC
Appearance and behaviour
Speech
Emotion (mood and affect)
Perception
Thought content and process
Insight and judgment
Cognition

Speech
- rate (i.e. pressured, slowed), rhythm, volume, tone, quantity, spontaneity, latency, language fluency, articulation

Mood and Affect
- mood: subjective emotional state (in patient's own words)
- affect: objective emotional state inferred from emotional responses to stimuli; described in terms of
  - quality (euthymic, depressed, elevated, anxious, irritable)
  - range (full, restricted, flat, blunted)
  - stability (continuum from fixed to labile)
  - mood congruence (inferred by comparing the patient's subjective mood with their affect)
- many clinicians use a 0-10 scale (0: worst; 10: best) when rating mood to get a subjective norm for each patient that can help to monitor changes over time and with treatment

The MSE is analogous to the physical exam. It focuses on current signs, affect, behaviour, and cognition

Spectrum of Affect
Full > Restricted > Blunted > Flat; quality (euthymic, depressed, anxious, elated)

Perception
- hallucination: sensory perception in the absence of appropriate stimuli that is similar in quality to a true perception
  - auditory (most common), visual, gustatory, olfactory, tactile
- illusion: misperception of a real external stimulus (i.e. mistaking a coat on a rack as a person late at night)
- depersonalization: change in self-awareness such that the person feels unreal, distant, or detached from their body, and/or unable to feel emotion
- derealization: feeling that the world/outer environment is unreal

There is poor correlation between clinical impression of suicide risk and frequency of attempts

Thought Process/Form
- coherence (coherent, incoherent)
- stream
  - goal-directed: clearly answers questions in a linear, organized, logical fashion
  - circumstantial: speech that is indirect and delayed in reaching its goal; eventually comes back to the point
  - tangential: speech is oblique or irrelevant; does not come back to the original point
  - loosening of associations/derailment: illogical shifting between topics
  - flight of ideas: quickly skipping from one idea to another where the ideas are marginally connected, usually associated with racing thoughts in mania
  - word salad: jumble of words lacking meaning or logical coherence
- perseveration: repetition of the same verbal or motor response to stimuli
- echolalia: repetition of phrases or words spoken by someone else
- thought blocking: sudden cessation of flow of thought and speech
- clang associations: speech based on sound such as rhyming or punning
- neologism: use of novel words or of existing words in a novel fashion

Thought Content
- major themes discussed by patient
- suicidal ideation/homicidal ideation: frequency and pervasiveness of thoughts, plan, intent, active vs. passive, protective factors
- preoccupations, ruminations: reflections/thoughts at length, not fixed or false
- obsession: recurrent and persistent thought, impulse, or image which is intrusive or inappropriate and unwanted
  - cannot be stopped by logic or reason
  - causes marked anxiety and distress
  - common themes: contamination, orderliness, sexual, pathological doubt/worry/guilt
- magical thinking (i.e. superstition, belief that thinking something will make it happen), normal in children and certain cultures
- ideas of reference: similar to delusion of reference, but less fixed (the reality of the belief is questioned)
- overvalued ideas: unusual/odd beliefs that are not of delusional proportions
- first rank symptoms of schizophrenia: thought insertion/withdrawal/broadcasting (all delusional ideas)
- delusion: a fixed false belief that is out of keeping with a person's cultural or religious background and is firmly held despite incontrovertible proof to the contrary

Insight
- ability to realize that they have a mental health concern and to appreciate its implications as it relates to functioning and benefits of treatment: none, limited, partial, or full

Judgment
- recent behaviours as they relate to safety, social functioning, treatment decisions

Cognition
- level of consciousness (alert, reduced, obtunded)
- orientation: time, place, person
- memory: immediate, recent, or remote
- global evaluation of intellect (below average, average, or above average, in keeping with person's education)
- intellectual functions: attention, concentration, calculation, abstraction (proverb interpretation, similarities test), language, communication
- MMSE/MoCA useful as standard screening assessments of cognition

Cognitive Assessment
Use MMSE to assess
- Orientation (time and place)
- Memory (immediate and delayed recall)
- Attention and concentration
- Language (comprehension, reading, writing, repetition, naming)
- Spatial ability (intersecting pentagons)

Gross screen for cognitive dysfunction: Total score is out of 30; <26 abnormal, 20-26 mild, 10-19 moderate, <10 severe

The key to differentiating between obsessions and delusions is that obsessions are usually ego dystonic, meaning unwanted and not fitting in with a person's goals and self-image, while delusions are ego syntonic

Delusions (Absolute Beliefs)
- Persecutory: belief that others are trying to cause harm to you
- Reference: interpreting ordinary, regular events/celebrities as having direct reference to you
- Erotomania: belief that another is in love with you
- Grandiose: belief that he or she has special powers, talents, or abilities
- Religious: belief of receiving instructions/powers from a higher being; of being a higher being
- Somatic: belief that you have a physical disorder/defect
- Nihilistic: belief that things do not exist; a sense that everything is not real

Assessing Insight and Judgment
Insight
- Acknowledgment of symptoms as a departure from baseline or source of suffering
- Attribution of symptoms to illness or acceptance as such explanation as part of the process
- Acknowledgement of need for treatment (Why are you in the hospital? Why are you taking this medication? What would happen if you stopped taking it?)

Judgment
Can be observed from collected history and patient's appearance and actions. Are they:
- Dressed appropriately for the weather?
- Acting appropriately in the given situation?
- Taking care of self and/or dependents?

Assessment and Plan

Historical Multiaxial Model
- since DSM-5, this model is no longer used for psychiatric diagnosis. Instead, relevant psychiatric and medical diagnoses are simply listed. Nevertheless, we offer it here as a possible framework for psychiatric patient assessment, as many physicians still employ it

Multiaxial Assessment
- Axis I: DSM-5 diagnoses (preferred and differential)
- Axis II: personality disorders, intellectual disability
- Axis III: medical conditions potentially relevant to understanding/management of the mental disorder
- Axis IV: psychosocial and environmental issues
- Axis V: Global Assessment of Functioning (GAF, 0 to 100) incorporating effects of axes I to IV

After History and MSE, the assessment and plan is recorded

Assessment/Problem Formulation
- identify predominant symptom cluster (mood, anxiety, psychosis) that causes the most distress/interference and persists when other symptom categories are not present (i.e. psychosis in the absence of mood symptoms)
- dominating symptoms will direct differential
- consider current issues as they relate to an individual considering three domains: biological, psychological, and social
- for each category: predisposing, precipitating, perpetuating, and protecting factors are considered

Always rule out substance use and other medical causes before considering psychiatric causes

Approach to Management
- consider short-term and long-term, and three types: biological (i.e. pharmacotherapy, ECT), psychological (i.e. CBT), and social (i.e. supports, finance/employment/return to work, housing, social activity, recreation, medication/psychotherapy coverage)

Suicide

Importance
- must be screened for in every encounter; part of risk assessment along with violent/homicidal ideation

Suicidal Ideation Assessment
- Asking patients about suicide will not give them the idea or the incentive to die by suicide
- The best predictor of completed suicide is a history of attempted suicide
- The most common psychiatric disorders associated with completed suicide are mood disorders and alcohol use disorders

Approach
- ask every patient: i.e. "Have you had any thoughts of wanting to harm or kill yourself?"
- classify ideation
  - passive ideation ("death wish"): where patient would rather not be alive but currently has no active plan for suicide
    - i.e. "I would rather not wake up" or "I would not mind if a car hit me"
  - active ideation
    - i.e. "I think about killing myself"
- assess risk
  - plan: "Do you have a plan as to how you would end your life?"
  - intent: "Do you think you would actually carry out this plan?" "If not, why not?"
  - past attempts: number, lethality, outcome, medical intervention, while intoxicated?, precipitants
  - if intoxicated on the first approach, reassess when sober
- assess suicidal ideation
  - onset and frequency of thoughts: "When did this start?" or "How often do you have these thoughts?"
  - control over suicidal ideation: "How do you cope when you have these thoughts?" "Could you call someone for help?"
  - intention: "Do you want to end your life?" or "Do you wish to kill yourself?"
  - intended lethality: "What do you think would happen if you actually took those pills?"
  - access to means: "How will you get a gun?" or "Which bridge do you think you would go to?"
  - time and place: "Have you picked a date and place? Is it in an isolated location?"
  - provocative factors: "What makes you feel worse (i.e. being alone)?"
  - protective factors: "What keeps you alive (i.e. friends, family, pets, faith, therapist)?"
  - final arrangements: "Have you written a suicide note? Made a will? Given away your belongings?"
  - practiced suicide or aborted attempts: "Have you ever put the gun to your head?" "Held the medications in your hand?" "Stood at the bridge?"
  - ambivalence: "I wonder if there is a part of you that wants to live, given that you came here for help?"
  - determine level of risk and develop treatment/safety plan

Suicide Risk Factors

SAD PERSONS
Sex (male)
Age >60 yr
Depression
Previous attempts
Ethanol abuse
Rational thinking loss (delusions, hallucinations, hopelessness)
Suicide in family
Organized plan
No spouse (no support systems)
Serious illness, intractable pain

Assessment of Suicide Attempt
- setting (isolated vs. others present/chance of discovery)
- planned vs. impulsive attempt, triggers/stressors
- substance use/intoxication
- medical attention (brought in by another person vs. brought in by self to ED)
- time lag from suicide attempt to ED arrival
- expectation of lethality, dying
- reaction to survival (guilt/remorse vs. disappointment/self-blame)
- evidence of escalation in potential lethal means

Epidemiology
- attempted:completed = 20:1 (100:1 in younger persons; 4:1 in older persons)
- M:F=1:4 for attempts, 3:1 for completed

Risk Factors

- epidemiologic factors
  - age: increases after age 14, second most common cause of death for ages 15-24, highest rates of completion in persons >75 yr
  - sex: male
  - race/ethnic background: White people or Indigenous peoples in Canada
  - marital status: widowed/divorced
  - living situation: alone; no children <18 y/o in the household
  - other: stressful life events, or access to firearms
- psychiatric factors
  - past suicide attempt(s)
  - eating disorders
  - bipolar disorder
  - major depression
  - mixed drug misuse
  - panic disorder
  - schizophrenia
  - personality disorder
  - alcohol use
- psychosocial factors
  - recent, severe stressful life event (relationship, financial, trauma)
- psychiatric disorders
  - mood disorders (15% lifetime risk in depression; higher in bipolar)
  - anxiety disorders (especially panic disorder)
  - schizophrenia (10-15% risk)
  - substance use disorder (especially alcohol – 15% lifetime risk)
  - eating disorders (5% lifetime risk)
  - adjustment disorder
  - conduct disorder
  - personality disorders (borderline, antisocial)
- past history
  - prior suicide attempt(s), most recent attempt
  - family history of suicide attempt/completion

Clinical Features

- symptoms associated with suicide:
  - hopelessness
  - anhedonia
  - insomnia
  - severe anxiety
  - impaired concentration
  - psychomotor agitation

Management

- proper documentation of the clinical encounter and rationale for management is essential
- for higher risk patients (with a plan and intention to act, have access to lethal means, recent social stressors, and symptoms suggestive of a psychiatric disorder)
  - hospitalization should be strongly considered
  - do not leave patient alone; remove potentially dangerous objects from room
  - if patient refuses to be hospitalized, complete form for involuntary admission (Form 1) and must give patient Form 30 to notify them of their admission (in Ontario)
- for lower risk patients (not actively suicidal, with no active plan, or access to lethal means)
  - discuss protective factors and supports in their life, remind them of what they live for, promote survival skills that helped them through previous suicide attempts
  - make a safety plan that could include an agreement that they will:
    - not harm themselves
    - avoid alcohol, drugs, and situations that may trigger suicidal thoughts
    - follow-up with you at a designated time
    - contact a health care worker, call a crisis line, or go to an emergency department if they feel unsafe or if their suicidal feelings return or intensify
- patients with depression: consider hospitalization if symptoms severe or if psychotic features are present; otherwise outpatient treatment with good supports and pharmacotherapy
- patients with alcohol- or substance-related issues: suicidality usually resolves with abstinence for a few days; if not, suspect depression
- patients with personality disorders: crisis intervention, may or may not hospitalize
- patients with schizophrenia/psychosis: hospitalization might be necessary
- patients with parasuicidal behaviours/self-mutilation: long-term psychotherapy with brief crisis intervention when necessary

Psychotic Disorders

Definition
- characterized by a significant impairment in reality testing
- positive symptoms
  - delusions or hallucinations (with or without insight into their pathological nature)
  - grossly disorganized or abnormal motor behaviours (including catatonia)
  - formal thought disorder
- negative symptoms of schizophrenia
  - diminished emotional expression (i.e. affective flattening)
  - anhedonia
  - avolition
  - alogia
  - asociality

Differential Diagnosis of Psychosis

Approach
- differentiate among psychotic disorders and distinguish them from other primary diagnoses with psychotic features
- consider symptoms, persistence, and time
- symptoms: the primary diagnosis needs full criteria to be met
  - mood: depressive episodes with psychotic features, manic episodes with psychotic features
  - psychotic: consider symptoms in Criterion A of schizophrenia (see *Criteria for Schizophrenia*, PS8)
- persistence: is there a time when certain symptom clusters are present without other clusters?
  - i.e. if there is a period of time with mood symptoms but not psychotic symptoms, consider mood disorder
  - i.e. if psychotic symptoms occur only with mood symptoms, consider mood disorder with psychotic features
  - i.e. if during a 2 wk period where psychotic symptoms persist in the absence of mood symptoms, consider schizoaffective disorder
  - i.e. if long periods with psychotic symptoms and brief or rare mood symptoms, consider schizophrenia
- time: how long have the symptoms been present?

Table 1. Differentiating Psychotic Disorders

Disorder	Psychotic Symptoms	Duration
Brief Psychotic Disorder	≥1 positive symptoms of criterion A	<1 mo with eventual full return to premorbid functioning
Schizophreniform Disorder	Criterion A	1-6 mo
Schizophrenia	Criterion A	>6 mo
Schizoaffective Disorder	Criterion A + major mood episode (MDE or manic), ≥2 wk of psychotic symptoms without mood symptoms	>1 mo
Delusional Disorder	One or more delusions (if hallucinations, related to delusional theme)	>1 mo
Substance-Induced Psychotic Disorder	Delusions or hallucinations	Onset during intoxication/withdrawal, resolve in <1 mo without use
2° to Mood Disorder	Mood symptoms dominant + delusions/ hallucinations (mood congruent)	Psychosis may be present only for the duration of the mood episode

Relevant Investigations
- CBC, electrolytes (including extended electrolytes), creatinine, glucose, urinalysis, urine drug screen, TSH, and vitamin B_{12}
- LFTs, fasting lipids, HbA1C to obtain baseline levels prior to antipsychotic initiation
- ECG (several antipsychotics affect cardiac conduction)
- if clinically indicated, order infectious work-up, inflammatory markers, and brain imaging

Delusions: fixed, false beliefs that are not amenable to change in light of conflicting evidence
Hallucinations: perceptual experiences occurring without an external stimulus

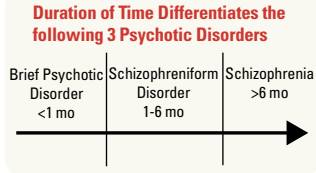

Figure 1. Differentiating psychotic disorders by duration

DDx for Psychosis
- Primary psychotic disorders: schizophrenia, schizophreniform, brief psychotic, schizoaffective, delusional disorder
- Mood disorders: MDD with psychotic features, bipolar disorder (manic or depressive episode with psychotic features)
- Personality disorders: schizotypal, schizoid, borderline, paranoid, obsessive-compulsive (they predispose to psychosis but presence of psychotic symptoms require another diagnosis)
- General medical conditions: tumour, head trauma, dementia, delirium, metabolic, infection, stroke, temporal lobe epilepsy
- Substance-induced psychosis: onset during intoxication or withdrawal, prescribed medications, toxins

Management of Acute Psychosis and Mania
- Ensure safety of self, patient, and other patients
- Have an exit strategy
- Decrease stimulation
- Assume a non-threatening stance
- IM medications (benzodiazepine and antipsychotic) often needed as patient may refuse oral medication
- Physical restraints may be necessary
- Do not use antidepressants or stimulants

Schizophrenia

DSM-5 DIAGNOSTIC CRITERIA FOR SCHIZOPHRENIA

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. two (or more) of the following, each present for a significant portion of time during a 1 mo period (or less if successfully treated). At least one of these must be (1), (2), or (3)
   1. delusions
   2. hallucinations
   3. disorganized speech (e.g. frequent derailment or incoherence)
   4. grossly disorganized or catatonic behaviour
   5. negative symptoms (i.e. diminished emotional expression or avolition)

B. for a significant portion of time since the onset of the disturbance, level of functioning in one or more major areas (e.g. work, interpersonal relations, self-care) is markedly below the level achieved prior to the onset (or when the onset is in childhood or adolescence, there is failure to achieve expected level of interpersonal, academic, or occupational functioning)

C. continuous signs of the disturbance persist for at least 6 mo. This 6 mo period must include at least 1 mo of symptoms (or less if successfully treated) that meet Criterion A (i.e. active-phase symptoms) and may include periods of prodromal or residual symptoms. During these prodromal or residual periods, the signs of the disturbance may be manifested by only negative symptoms or by two or more symptoms listed in Criterion A present in an attenuated form (e.g. odd beliefs, unusual perceptual experiences)

D. schizoaffective disorder and depressive or bipolar disorder with psychotic features have been ruled out because either 1) no major depressive or manic episodes have occurred concurrently with the active-phase symptoms, or 2) if mood episodes have occurred during active-phase symptoms, they have been present for a minority of the total duration of the active and residual periods of the illness

E. the disturbance is not attributable to the physiological effects of a substance (e.g. drug of abuse, medication) or another medical condition

F. if there is a history of autism spectrum disorder or a communication disorder of childhood onset, the additional diagnosis of schizophrenia is made only if prominent delusions or hallucinations, in addition to the other required symptoms of schizophrenia are also present for at least 1 mo (or less if successfully treated)

- **specifiers**: type of episode (e.g. first episode, multiple episodes, continuous), in acute episode/partial/full remission, with catatonia, current severity based on quantitative assessment of primary symptoms of psychosis

Epidemiology

- prevalence: 0.3-0.7%, M:F=1:1
- mean age of onset: females late-20s with a 2nd peak in mid-life; males early- to mid-20s (some cases with late onset)
- suicide risk: 5-6% die by suicide, 20% attempt suicide

Etiology

- multifactorial: disorder is a result of interaction between both biological and environmental factors
  - genetic: 40% concordance in monozygotic (MZ) twins; 46% if both parents have schizophrenia; 10% of dizygotic (DZ) twins, siblings, children affected; vulnerable genes include Disrupted-in-Schizophrenia 1 (DISC1); neuregulin 1 (NRG 1); dystrobrevin binding protein/dysbindin (DTNBP1); catechol-O-methyltransferase (COMT); d-amino acid oxidase activator (DAOA); metabotropic glutamate receptor 3 (GRM3); and brain-derived neurotrophic factor (BDNF)
  - neurochemistry ("dopamine hypothesis"): excess activity in the mesolimbic dopamine pathway may mediate the positive symptoms of psychosis, while decreased dopamine in the prefrontal cortex may mediate negative and cognitive symptoms. GABA, glutamate, and ACh dysfunction are also thought to be involved
  - neuroanatomy: decreased frontal lobe function; asymmetric temporal/limbic function; decreased basal ganglia function; subtle changes in thalamus, cortex, corpus callosum, and ventricles; cytoarchitectural abnormalities
  - neuroendocrinology: abnormal growth hormone, prolactin, cortisol, and ACTH
  - neuropsychology: global defects seen in attention, language, and memory suggest disrupted connectivity of neural networks
  - environmental: indirect evidence of cannabis use, geographical variance, winter season of birth, obstetrical complications, and prenatal viral exposure

Pathophysiology

- neurodegenerative theory: natural history may be a rapid or gradual decline in function and ability to communicate
  - glutamate system may mediate progressive degeneration by excitotoxic mechanism which leads to production of free radicals
- neurodevelopmental theory: abnormal development of the brain from prenatal life
  - neurons fail to migrate correctly, make inappropriate connections, and undergo apoptosis in later life

Relationship Between Duration of Untreated Psychosis (DUP) and Outcome in First-Episode Schizophrenia
Am J Psychiatry 2005;162:1785-1804
Purpose: To review the association between DUP and symptom severity at first treatment contact, and between DUP and treatment outcomes.
Methods: Critical review and meta-analysis of studies involving patients with non-affective psychotic disorders at or close to first treatment.
Results: 43 studies with 4177 patients were included. Shorter DUP was associated with greater response to antipsychotic treatment, as measured by global psychopathology, positive symptoms, negative symptoms, and functional outcomes. At the time of treatment initiation, longer DUP was associated with the severity of negative symptoms but not with the severity of positive symptoms, global psychopathology, or neurocognitive function.
Conclusions: DUP may be a potentially modifiable prognostic factor.

Duration of Untreated Psychosis as Predictor of Long-term Outcome in Schizophrenia: Systematic Review and Meta-analysis
Brit J Psychiatry 2014;205:88-94
Purpose: To review the association between DUP and long-term outcomes of schizophrenia.
Methods: A systematic review and meta-analysis on the effects of duration of untreated psychosis on clinical, social, or quality of life outcomes at least 2 yr following psychosis in people with schizophrenia.
Results: 33 studies were included. Longer DUP was associated with poorer general symptomatic outcome, more severe positive and negative symptoms, lesser likelihood of remission, and poorer social functioning and global outcomes. Longer DUP was not associated with employment, quality of life, or hospital treatment.

Disorganized Behaviours in Schizophrenia

- Catatonic stupor: fully conscious but mute, unresponsive, immobile, and maintaining bizarre positions for a long time
- Catatonic excitement: uncontrolled and aimless motor activity, extreme agitation
- Stereotypy: repeated but non-goal-directed movement (i.e. rocking)
- Mannerisms: goal-directed activities that are odd or out of context (i.e. grimacing)
- Echopraxia: imitates movements and gestures of others
- Automatic obedience: carries out simple commands in robot-like fashion
- Negativism: refuses to cooperate with simple requests for no apparent reason
- Inappropriate affect, neglect of self-care, other odd behaviours (random shouting)

Comorbidity
- substance use disorders (>50% use tobacco)
- anxiety disorders
- reduced life expectancy secondary to medical comorbidities (i.e. obesity, diabetes, metabolic syndrome, CV/pulmonary disease)

Management of Schizophrenia
- biological/somatic
  - acute treatment and maintenance: antipsychotics (risperidone, aripiprazole, haloperidol, paliperidone; clozapine if resistant); regimens of IM q2-4 wk. Long-acting injectables (LAI or depot) shown to be more effective in reducing relapse and rehospitalization compared with oral alternatives
  - adjunctive: ± mood stabilizers (for aggression/impulsiveness - lithium, valproate, carbamazepine) ± anxiolytics ± ECT
  - maintenance treatment for at least 1-2 yr after the first episode, at least 5 yr after multiple episodes (relapse causes severe deterioration)
- psychosocial
  - psychotherapy (individual, family, group), supportive, CBT (see Table 14, PS51)
  - ACT (Assertive Community Treatment): mobile mental health teams that provide individualized treatment in the community and help patients with medication adherence, basic living skills, social support, job placements, resources
  - social skills training, employment programs, disability benefits
  - housing (group home, boarding home, transitional home)

Course and Prognosis
- majority of individuals display some type of prodromal phase
- course is variable: some individuals have exacerbations and remissions while others remain chronically ill; accurate prediction of the long-term outcome is not possible
- positive symptoms typically diminish with treatment; negative symptoms tend to be most persistent and cognitive symptoms may not improve
- over time: 1/3 improve, 1/3 remain the same, 1/3 worsen

Cannabis Use and Earlier Onset of Psychosis
Arch Gen Psychiatry 2011;68:555-561
Purpose: To examine the extent to which cannabis, alcohol, and other psychoactive drugs affect the age of onset of psychosis.
Method: A systematic review and meta-analysis. English studies were included that compared two cohorts: patients who used substances vs. patients who did not use substances.
Results: 83 studies were included. The age of onset in cannabis users was 2.7 yr younger than in nonusers. For broadly defined substance use, age of onset of psychosis was 2.0 yr earlier than for nonusers. Alcohol use was not associated with significantly earlier age of psychosis.
Conclusions: These results provide evidence that cannabis plays a role in earlier onset of psychosis.

Good Prognostic Factors
- Acute onset
- Later age of onset
- Shorter duration of prodrome
- Female gender
- Good cognitive functioning
- Good premorbid functioning
- No family history
- Presence of affective symptoms
- Absence of structural brain abnormalities
- Good response to drugs
- Good support system

Schizophreniform Disorder

Diagnosis
- criteria A, D, and E of schizophrenia are met; an episode of the disorder lasts for > 1 mo but < 6 mo
  - if the symptoms have extended past 6 mo the diagnosis becomes schizophrenia
  - specifiers: with/without good prognostic features (e.g. acute onset, confusion/perplexity, good premorbid functioning, absence of blunt/flat affect), with catatonia, current severity based on quantitative assessment of primary symptoms of psychosis

Treatment
- similar to acute schizophrenia

Prognosis
- better than schizophrenia; 1/3 recover within 6 mo, 2/3 progress to schizophrenia

Brief Psychotic Disorder

Diagnosis
- criteria A1-A4, D, and E of schizophrenia are met; an episode lasts for at least 1 d, but less than 1 mo with eventual full return to premorbid level of functioning
- specifiers: with/without marked stressors, with postpartum onset, with catatonia, current severity
- can occur after a stressful event or postpartum (see *Postpartum Mood Disorders*, PS14)

Treatment
- secure/safe environment, antipsychotics, and anxiolytics

Prognosis
- good, self-limiting, should return to pre-morbid function within 1 mo

Schizoaffective Disorder

DSM-5 DIAGNOSTIC CRITERIA FOR SCHIZOAFFECTIVE DISORDER

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. an uninterrupted period of illness during which there is a major mood episode concurrent with Criterion A of schizophrenia
B. delusions or hallucinations for 2 or more wk in the absence of a major mood episode during the lifetime duration of the illness
C. symptoms that meet criteria for a major mood episode are present for the majority of the total duration of the active and residual periods of the illness
D. the disturbance is not attributable to the effects of a substance or another medical condition

- **specifiers**: bipolar type, depressive type, with catatonia, type of episode (i.e. first episode, multiple episode), severity

Non-bizarre delusions involve situations that could occur in real life (i.e. being followed, poisoned, loved at a distance) Bizarre delusions involve situations that cannot occur in real life (i.e. being kidnapped by aliens, having one's organs stolen)

Epidemiology

- one-third as prevalent as schizophrenia; schizoaffective disorder bipolar type more common in young adults, schizoaffective disorder depressive type more common in older adults
- depressive symptoms correlated with higher suicide risk (lifetime risk 5%)

Treatment

- antipsychotics, mood stabilizers, and antidepressants

Prognosis

- between that of schizophrenia and of mood disorder

Delusional Disorder

DSM-5 DIAGNOSTIC CRITERIA FOR DELUSIONAL DISORDER

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. the presence of one (or more) delusions with a duration of 1 mo or longer
B. criterion A for schizophrenia has never been met
   Note: hallucinations, if present, are not prominent and are related to the delusional theme
C. apart from the impact of the delusion(s) or its ramifications, functioning is not markedly impaired, and behaviour is not obviously bizarre or odd
D. if manic or major depressive episodes have occurred, these have been brief relative to the duration of the delusional periods
E. the disturbance is not attributable to the physiological effects of a substance or another medical condition and is not better explained by another mental disorder

- **subtypes**: erotomanic, grandiose, jealous, persecutory, somatic, mixed, unspecified
- **further specify**: bizarre content, type of episode (e.g. first episode, multiple episode), severity

Treatment

- antipsychotics, psychotherapy, and antidepressants

Prognosis

- may respond well to antipsychotics but most patients refuse them and have chronic, unremitting course; some maintain a high level of functioning; some progress to schizophrenia

Mood Disorders

Definitions

- accurate diagnosis of a mood disorder requires a careful past medical and psychiatric history to detect past mood episodes and to rule out whether these episodes were secondary to substance use, a medical condition, etc.
- mood episodes represent a combination of symptoms comprising a predominant mood state that is abnormal in quality or duration (i.e. major depressive, manic, mixed, hypomanic). DSM-5 Criteria for mood episodes are listed below
- types of mood disorders include:
  - depressive (MDD, persistent depressive disorder)
  - bipolar (bipolar I/II disorder, cyclothymia)
  - induced by or due to ("secondary to") a general medical condition, substance, medication, or other psychiatric condition

Medical Workup of Mood Disorder

- routine screening: physical exam, CBC, extended electrolytes, LFT, renal and thyroid function tests, drug screen, medications list
- additional screening: B_{12} (in older people), neurological consultation, chest x-ray, ECG, head imaging

Mood Episodes

DSM-5 DIAGNOSTIC CRITERIA FOR MAJOR DEPRESSIVE EPISODE

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. ≥5 of the following symptoms have been present during the same 2 wk period and represent a change from previous functioning; at least one of the symptoms is either 1) depressed mood or 2) loss of interest or pleasure (anhedonia)
   Note: Do not include symptoms that are clearly attributable to another medical condition
   - depressed mood most of the day, nearly every day, as indicated by either subjective report or observation made by others
   - markedly diminished interest or pleasure in all, or almost all, activities most of the day, nearly every day
   - significant and unintentional weight loss/weight gain, or decrease/increase in appetite nearly every day
   - insomnia or hypersomnia nearly every day
   - psychomotor agitation or retardation nearly every day
   - fatigue or loss of energy nearly every day
   - feelings of worthlessness or excessive or inappropriate guilt (which may be delusional) nearly every day (not merely self-reproach or guilt about being sick)
   - diminished ability to think or concentrate, or indecisiveness, nearly every day
   - recurrent thoughts of death (not just fear of dying), recurrent suicidal ideation without a specific plan, or a suicide attempt or a specific plan for committing suicide
B. the symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning
C. the episode is not attributable to the direct physiological effects of a substance or a GMC

Criteria for Depression (≥5)

MSIGECAPS
Mood: depressed
Sleep: increased/decreased
Interest: decreased
Guilt
Energy: decreased
Concentration: decreased
Appetite: increased/decreased
Psychomotor: agitation/retardation
Suicidal ideation

DSM-5 CRITERIA FOR MANIC EPISODE

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. a distinct period of abnormally and persistently elevated, expansive, or irritable mood and abnormally and persistently increased goal-directed activity or energy, lasting ≥1 wk and present most of the day, nearly every day (or any duration if hospitalization is necessary)
B. during the period of mood disturbance and increased energy or activity, ≥3 of the following symptoms have persisted (4 if the mood is only irritable) and have been present to a significant degree and represent a noticeable change from usual behaviour
   - inflated self-esteem or grandiosity
   - decreased need for sleep (e.g. feels rested after only 3 h of sleep)
   - more talkative than usual or pressure to keep talking
   - flight of ideas or subjective experience that thoughts are racing
   - distractibility (i.e. attention too easily drawn to unimportant or irrelevant external stimuli)
   - increase in goal-directed activity (either socially, at work or school, or sexually) or psychomotor agitation
   - excessive involvement in pleasurable activities that have a high potential for painful consequences (e.g. engaging in unrestrained shopping sprees, sexual indiscretions, or foolish business investments)
C. the mood disturbance is sufficiently severe to cause marked impairment in social or occupational functioning or to necessitate hospitalization to prevent harm to self or others, or there are psychotic features
D. the episode is not attributable to the physiological effects of a substance or another medical condition
   Note: A full manic episode that emerges during antidepressant treatment but persists at a fully syndromal level beyond the physiological effect of that treatment is sufficient evidence for a manic episode, and therefore, a bipolar I diagnosis
   Note: Criteria A-D constitute a manic episode. At least one lifetime manic episode is required for the diagnosis of bipolar I disorder

Criteria for Mania (≥3)

GST PAID
Grandiosity
Sleep (decreased need)
Talkative
Pleasurable activities, Painful consequences
Activity (increased)
Ideas (flight of)
Distractible

Hypomanic Episode

- criterion A and B of a manic episode is met, but duration is ≥4 d
- episode associated with an unequivocal change in functioning that is uncharacteristic of the individual when not symptomatic and observable by others
- episode is not severe enough to cause marked impairment in social or occupational functioning or to necessitate hospitalization
- absence of psychotic features (if these are present the episode is, by definition, manic)

Mixed Features
- episode specifier in a manic, hypomanic, or depressive episode of BDI/II that indicates the presence of both depressive and manic symptoms concurrently, classified by the disorder and primary mood episode (i.e. BDI, current episode manic, with mixed features)
- clinical importance due to increased suicide risk and appropriate treatment
- if found in patient diagnosed with major depression, there is a high index of suspicion for BD
- while meeting the full criteria for a MDE, the patient has on most days ≥3 of criteria B for a manic episode
- while meeting the full criteria for a manic/hypomanic episode, the patient has on most days ≥3 of criteria A for a depressive episode (the following criterion A cannot count: psychomotor agitation, insomnia, difficulties concentrating, or weight changes)

Depressive Disorders

MAJOR DEPRESSIVE DISORDER

DSM-5 DIAGNOSTIC CRITERIA FOR MAJOR DEPRESSIVE DISORDER (MDD)
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. presence of a single MDE (vs. recurrent, which requires presence of two or more MDEs; to be considered separate episodes, there must be an interval of at least 2 consecutive mo in which criteria are not met for a MDE)
B. the MDE is not better accounted for by schizoaffective disorder and is not superimposed on schizophrenia, schizophreniform disorder, delusional disorder, or psychotic disorder NOS
C. there has never been a manic episode or a hypomanic episode

- **Note**: This exclusion does not apply if all of the manic-like, or hypomanic-like episodes are substance or treatment-induced or are due to the direct physiological effects of another medical condition
- **specifiers**: with anxious distress, mixed features, melancholic features, atypical features, mood-congruent psychotic features, mood-incongruent psychotic features, catatonia, peripartum onset, seasonal pattern

Antidepressants for Depression in Physically Ill People
Cochrane DB Syst Rev 2010;CD007503
Purpose: To determine the efficacy of antidepressants in treating depression in people with comorbid physical illness.
Methods: Systematic review of RCTs comparing the efficacy of antidepressants vs. placebo in the treatment of major depression, adjustment disorder, and dysthymia in adults with comorbid depression and physical illness. Physical illness was defined as any medical condition known to have a biological underpinning where diagnosis is not purely symptom based.
Results: Fifty-one studies including 3603 participants were included in this review. Both tricyclic antidepressants and selective serotonin reuptake inhibitors were more effective than placebo at treating depression in adults with concurrent physical illness. Dry mouth and sexual dysfunction were more common in patients treated with an antidepressant.

Epidemiology
- Canadian annual/lifetime prevalence: 5%/11%
- peak prevalence age 15-25 yr (M:F=1:2)

Etiology
- biological
  - genetic: 65-75% MZ twins; 14-19% DZ twins, 2-4 fold increased risk in first-degree relatives
  - neurotransmitter dysfunction: decreased activity of 5-HT, NE, and DA at neuronal synapse; changes in GABA and glutamate; various changes detectable by fMRI
  - neuroendocrine dysfunction: abnormal HPA axis activity
  - neuroanatomy and neurophysiology: decreased hippocampal volume, increased size of ventricles; decreased REM latency and slow-wave sleep; increased REM length
  - immunologic: increased pro-inflammatory cytokines IL-6 and TNF
  - secondary to medical condition, medication, substance use disorder
- psychosocial
  - cognitive (i.e. distorted schemata, Beck's cognitive triad: negative views of oneself, the world, and the future)
  - environmental factors (i.e. job loss, bereavement, history of abuse or neglect, early life adversity)
  - comorbid psychiatric diagnoses (i.e. anxiety, substance use disorder, developmental disability, dementia, eating disorder)

Risk Factors
- sex: F:M=2:1
- family history: depression, alcohol use disorder, suicide attempt or completion
- childhood experiences: loss of parent before age 11, negative home environment (abuse, neglect)
- personality: neuroticism, insecure, dependent, obsessional
- recent stressors: illness, financial, legal, relational, academic
- lack of intimate, confiding relationships or social isolation
- low socioeconomic status

Clinically Significant Depressive Symptoms in the Elderly
- affects about 15% of community residents >65 y/o; up to 50% in nursing homes
- high suicide risk due to social isolation, chronic medical illness, and decreased independence
- suicide peak: males ages 80-90, females ages 50-65
- low mood or dysphoria may not be a reliable indicator of depression in those >70 y/o
- often present with somatic complaints (i.e. changes in weight, sleep, energy; chronic pain) or anxiety symptoms
- may have prominent cognitive changes after onset of mood symptoms (dementia syndrome of depression)
- see Table 3, PS26, for a comparison of delirium and dementia

Treatment
- lifestyle: increased aerobic exercise, mindfulness-based stress reduction, sleep hygiene
- biological: SSRIs, SNRIs, other antidepressants, somatic therapies (see *Pharmacotherapy*, PS52 and *Somatic Therapies*, PS61)
  - for MDE of moderate or greater severity, 1st line pharmacotherapy are used: most 2nd generation antidepressants, with escitalopram, mirtazapine, sertraline, venlafaxine, agomelatine and citalopram showing evidence for superiority
  - for non or partial response, optimize the dose, switch to antidepressant with superiority, or add augmenting agent (i.e. aripiprazole, quetiapine, risperidone)
  - typical response to antidepressant treatment: physical symptoms improve at 2 wk, mood/cognition by 4 wk; if no improvement after 4 wk at the highest tolerated therapeutic dosage, alter regimen
  - ECT: currently fastest and most effective treatment for MDD. Consider in severe, psychotic, or treatment-resistant cases
  - rTMS: 1st line treatment for MDD for patients who have failed at least 1 antidepressant treatment. Efficacy equivalent to medications (but not to ECT) with good safety and tolerability
  - phototherapy: especially if seasonal component, shift work, sleep dysregulation
- psychological
  - individual therapy (CBT, interpersonal, behavioural activation, dynamic), group therapy, family therapy
- social: vocational rehabilitation, social skills training
- experimental: magnetic seizure therapy, deep brain stimulation, ketamine

Prognosis
- 1 yr after diagnosis of MDD without treatment: 40% of individuals will still have symptoms that are sufficiently severe to meet criteria for MDD, 20% will continue to have some symptoms that no longer meet criteria for MDD, 40% will have no symptoms

PERSISTENT DEPRESSIVE DISORDER

DSM-5 DIAGNOSTIC CRITERIA FOR PERSISTENT DEPRESSIVE DISORDER
Note: in DSM-IV-TR this was referred to as Dysthymic Disorder

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. depressed mood for most of the day, for more days than not, as indicated either by subjective account or observation by others, for ≥2 yr
   Note: In children and adolescents, mood can be irritable and duration must be at least 1 yr
B. presence, while depressed, of ≥2 of the following
   - poor appetite or overeating
   - insomnia or hypersomnia
   - low energy or fatigue
   - low self-esteem
   - poor concentration or difficulty making decisions
   - feelings of hopelessness
C. during the 2 yr period (1 yr for children or adolescents) of the disturbance, the person has never been without the symptoms in criteria A and B for more than 2 mo at a time
D. criteria for a major depressive disorder may be continuously present for 2 yr
E. there has never been a manic episode or a hypomanic episode, and criteria have never been met for cyclothymic disorder
F. the disturbance is not better explained by a persistent schizoaffective disorder, schizophrenia, delusional disorder, or other specified or unspecified schizophrenia spectrum and other psychotic disorder
G. the symptoms are not due to the direct physiological effects of a substance or another medical condition
H. the symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

- **specifiers**:
  - with anxious distress, mixed features, melancholic features, atypical features, mood-congruent psychotic features, mood-incongruent psychotic features, catatonia, peri-partum onset, seasonal pattern
  - partial remission, full remission
  - early onset (<21 y/o), late onset (>21 y/o)
  - with pure dysthymic syndrome (full criteria for MDE have not been met in at least preceding 2 yr), with persistent MDE (full criteria for MDE have been met throughout preceding 2 yr)
  - with intermittent MDEs, with current episode: full criteria for a MDE are currently met, but there have been periods of at least 8 wk in at least the preceding 2 yr with symptoms below the threshold for a full MDE
  - with intermittent MDEs, without current episode: full criteria for a MDE are not currently met, but there has been one or more MDEs in at least the preceding 2 yr
  - specify current severity: mild, moderate, severe

See Landmark Psychiatry Trials table for more information on TRANSFORM-2, which details the use of esketamine nasal spray for patients with treatment-resistant depression.

Epidemiology
- lifetime prevalence: 2-3%; M=F

Treatment
- psychological
  - traditionally, psychotherapy was the principal treatment for persistent depressive disorder; recent evidence suggests some (but generally inferior) benefit for pharmacological treatment. Combinations of the two may be most efficacious
- biological
  - antidepressant therapy: SSRIs (e.g. sertraline, escitalopram), TCAs (e.g. nortriptyline)

Postpartum Mood Disorders

Postpartum "Blues"
- transient period of mild depression, mood instability, anxiety, decreased concentration; considered to be normal in response to fluctuating hormonal levels, the stress of childbirth, and the increased responsibilities of motherhood
- occurs in 50-80% of mothers; begins 2-4 d postpartum, usually lasts 48 h, can last up to 10 d
- does not require psychotropic medication
- usually mild or absent: feelings of inadequacy, anhedonia, thoughts of harming baby, suicidal thoughts

MAJOR DEPRESSIVE DISORDER WITH PERIPARTUM ONSET (POSTPARTUM DEPRESSION)

Clinical Features
- this specifier can apply to a MDE with onset during pregnancy or within 4 wk following delivery
- typically lasts 2-6 mo; residual symptoms can last up to 1 yr
- may present with psychosis (rare, 0.2% – more frequent with prior post-partum mood episodes and post-partum mania)
- severe symptoms may include complete disinterest in baby, suicidal and infanticidal ideation

Epidemiology
- occurs in up to 3-6% of mothers, up to 50% risk of recurrence

Risk Factors
- previous history of a mood disorder (postpartum or otherwise), family history of mood disorder
- psychosocial factors: stressful life events, unemployment, marital conflict, lack of social support, unwanted pregnancy, colicky or sick infant

Treatment
- psychotherapy (CBT or IPT)
- short-term safety of maternal SSRIs for breastfeeding infants established; long-term effects unknown
- if depression severe or psychotic symptoms present, consider ECT

Prognosis
- impact on child development: increased risk of cognitive delay, insecure attachment, behavioural disorders
- treatment of mother improves outcome for child at 8 mo through increased mother-child interaction

Bipolar Disorders

BIPOLAR I / BIPOLAR II DISORDER

Definition
- Bipolar I Disorder
  - disorder in which at least one manic episode has occurred
  - if manic symptoms lead to hospitalization, or if there are psychotic symptoms, the diagnosis is bipolar I
  - commonly accompanied by at least 1 MDE but not required for diagnosis
  - time spent in mood episodes: 53% asymptomatic, 32% depressed, 9% cycling/mixed, 6% hypo/manic
- Bipolar II Disorder
  - disorder in which there is at least 1 MDE, 1 hypomanic episode, and no manic episodes
  - while hypomania is less severe than mania, bipolar II is not a "milder" form of bipolar I
  - time spent in mood episodes: 46% asymptomatic, 50% depressed, 1% cycling/mixed, 2% hypo/manic
  - bipolar II is often missed due to the severity and chronicity of depressive episodes and low rates of spontaneous reporting and recognition of hypomanic episodes

Selective Serotonin Reuptake Inhibitors in Pregnancy and Infant Outcomes
Paediatr Child Health 2011;16:562-63
Canadian Paediatric Society (CPS) clinical practice guideline recommendations: It is important to treat depression in pregnancy. There is no evidence that SSRIs increase the risk of major malformations. There is conflicting evidence concerning the association of paroxetine and cardiac malformations. SSRIs are not contraindicated while breast-feeding.

Antidepressant Use in Pregnancy and the Risk of Cardiac Defects
NEJM 2014 Jun 19;370(25):2397-2407
Background: It is uncertain whether selective serotonin-reuptake inhibitors (SSRIs) and other antidepressants during pregnancy are associated with increased risk of congenital cardiac defects. There are concerns about an association between paroxetine use and right ventricular outflow tract obstruction, and between sertraline use and ventricular septal defects.
Methods: Cohort study including 949504 women enrolled in Medicaid for a 7 yr period. The risk of major cardiac defects among infants born to women who took antidepressants during the 1st trimester was compared with the risk among infants born to women who did not use antidepressants. An unadjusted analysis was used, possible confounders were considered.
Results: Overall, the chance of infants not exposed to antidepressants born with a cardiac defect was 72.3 per 10000 infants, and infants with exposure was 90.1 per 10000 infants. The relative risks of any cardiac defect with the use of SSRIs were 1.06 (95% CI, 0.93 to 1.22) in the fully adjusted analysis restricted to women with depression. No significant association was found between the use of paroxetine and right ventricular outflow tract obstruction (RR, 1.07) or between the use of sertraline and ventricular septal defects (RR, 1.04).
Conclusions: No substantial increase in risk of cardiac malformations attributable to antidepressant use during the 1st trimester.

Bipolar II is quite often missed and many patients are symptomatic for up to a decade before accurate diagnosis and treatment

Patients with bipolar disorder are at higher risk for suicide when they switch from mania to depression, especially as they become aware of consequences of their behaviour during the manic episode

Classification
- classification of BD involves describing the disorder (I or II) and the current or most recent mood episode as either manic, hypomanic, or depressed
- specifiers: with anxious distress, hypo/manic/depressed with mixed features, rapid cycling, melancholic features, atypical features, mood-congruent or -incongruent psychotic features, catatonia, peripartum onset, seasonal pattern, rapid cycling (≥4 mood episodes in 1 yr)

Epidemiology
- lifetime prevalence: 1% BD I, 1.1% BD II, 2.4% Subthreshold BD; M:F = 1:1
- mean age of onset: 25 yr, usually MDE first, manic episode 6-10 yr after, average age of first manic episode: 32 yr

Risk Factors
- genetic: 60-65% of bipolar patients have family history of a major mood disorder, especially bipolar disorder
- clinical features of MDE history favouring bipolar over unipolar diagnosis: early age of onset (<25 yr), increased number of MDEs, psychotic symptoms, postpartum onset, anxiety disorders (especially separation, panic), antidepressant failure due to early "poop out" or hypomanic symptoms, early impulsivity and aggression, substance misuse, cyclothymic temperament, family history of bipolar disorder

Treatment
- lifestyle: psychoeducation regarding cycling nature of illness, ensure regular check ins, develop early warning system, "emergency plan" for manic episodes, promote stable routine (sleep, meals, exercise)
- biological: lithium, anticonvulsants, antipsychotics, ECT (if resistant); monotherapy with antidepressants should be avoided
  - mood stabilizers vary in their ability to treat (reduce symptoms acutely) or stabilize (prevent relapse and recurrence) manic and depressive symptoms; multi-agent therapy is common
  - treating mania: lithium, divalproex, carbamazepine (2nd line), SGA, ECT (2nd line), benzodiazepines (for acute agitation)
  - preventing mania: same as above but usually at lower dosages, minus ECT and benzodiazepines
  - treating depression: lithium, lurasidone, quetiapine, lamotrigine, antidepressants (2nd line, only with mood stabilizer), ECT (2nd line)
  - preventing depression: same as above plus aripiprazole, divalproex (note: quetiapine is first line in treating bipolar II depression)
  - mixed episode or rapid cycling: multi-agent therapy: lithium or divalproex + SGA (lurasidone, aripiprazole)
- psychological: supportive psychotherapy, CBT, IPT or interpersonal social rhythm therapy, family therapy
- social: vocational rehabilitation, consider leave of absence from school/work, assess capacity to manage finances, drug and EtOH cessation, sleep hygiene, social skills training, recruitment and education of family members

Course and Prognosis
- high suicide rate (15% mortality from suicide), especially depressive episodes in mixed states
- bipolar I and II disorder are chronic conditions with a relapsing and remitting course featuring alternating manic and depressive episodes; depressive symptoms tend to occur more frequently and last longer than manic symptoms
- can achieve high level of functioning between episodes
- may switch rapidly between depression and mania without any period of euthymia in between
- high recurrence rate for mania – 90% will have a subsequent episode in the next 5 yr
- long term follow-up of bipolar I – 15% well, 45% well with relapses, 30% partial remission, 10% chronically ill

CYCLOTHYMIA

Diagnosis
- presence of numerous periods of hypomanic and depressive symptoms (not meeting criteria for full hypomanic episode or MDE) for ≥2 yr; never without symptoms for >2 mo
- have never met criteria for MDE, manic or hypomanic episodes
- symptoms are not due to the direct physiological effects of a substance or GMC
- symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

Treatment
- similar to Bipolar I: mood stabilizer ± psychotherapy

Lithium is among few agents with proven efficacy in preventing suicide attempts and completions

Monotherapy with antidepressants should be avoided in patients with bipolar depression as patients can switch from depression into mania

The 4 L's for Bipolar Depression
Lithium, **L**amotrigine, **L**urasidone, Seroque**L**

A Randomized Controlled Trial of Cognitive Therapy for Bipolar Disorder: Focus on Long-Term Change
J Clin Psychiatry 2006;67:277-86
Purpose: To evaluate long-term change with cognitive therapy plus emotive techniques for the treatment of bipolar disorder.
Methods: Blinded RCT including patients with DSM-IV bipolar I or II disorder allocated to either a 6 mo trial of cognitive therapy (CT) with emotive techniques or treatment as usual. Both groups received mood stabilizers. Main outcomes were relapse rates, dysfunctional attitudes, psychosocial functioning, hopelessness, self-control, and medication adherence. Patients were assessed by independent raters blinded to treatment group.
Results: At 6 mo, CT patients experienced fewer depressive symptoms and fewer dysfunctional attitudes. There was a non-significant (p=0.06) trend to greater time to depressive relapse. At 12 mo follow-up, CT patients had lower Young Mania Rating scores and improved behavioural self-control. At 18 mo, CT patients reported less severity of illness.
Conclusions: CT appears to provide benefits in the 12 mo after completion of therapy.

Efficacy of Cognitive-Behavioural Therapy in Patients with Bipolar Disorder: A Meta-Analysis of Randomized Controlled Trials
PLoS One 2017;12(5):e0176849
Purpose: To determine the efficacy of cognitive behavioural therapy (CBT) in the treatment of type I and II bipolar disorder.
Methods: A systematic review and meta-analysis of RCTs of CBT in the treatment of adults with bipolar disorder.
Results: Nineteen RCTs including 1284 patients with type I or II BD were included. CBT lowered the relapse rate (pooled OR = 0.506; 95% CI = 0.278 −0.921) and improved depressive symptoms (g = −0.494; 95% CI = −0.963 to −0.026), mania severity (g = −0.581; 95% CI = −1.127 to −0.035), and psychosocial functioning (g = 0.457; 95% CI = 0.106–0.809). Greater effects were seen with CBT treatment duration >90 min. Relapse rates were lower in people with type I bipolar disorder.

Anxiety Disorders

Definition

- fear is a universal human experience which can serve as an adaptive mechanism to facilitate appropriate reactions to external threat
- anxiety may be seen as pathological fear when:
  - fear is greatly out of proportion to risk/severity of threat
  - response continues beyond existence of threat (prolonged, excessive, etc.) or becomes generalized to other similar or dissimilar situations
  - social or occupational functioning is impaired
- manifestations of anxiety are a result of the activation of the sympathetic nervous system and can be described through:
  - physiology: main brain structure involved is the amygdala; neurotransmitters involved include 5-HT, cholecystokinin, epinephrine, norepinephrine, and DA
  - psychology: one's thoughts about a given situation or stimulus contribute to the feeling of fear and perception of threat
  - behaviour: anxiety can lead to avoidance which can perpetuate the fear/avoidance
  - often comorbid with substance use and depression; more than 50% have multiple anxiety disorders
  - when starting medication for anxiety: start low, go slow, aim high and explain symptoms to expect prior to initiation of therapy to prevent non-adherence due to side effects
  - psychotherapy: individual or group CBT

Differential Diagnosis

Table 2. Differential Diagnosis of Anxiety Disorders

Cardiovascular	Post-MI, arrhythmia, congestive heart failure, pulmonary embolus, mitral valve prolapse
Respiratory	Asthma, COPD, pneumonia
Endocrine	Hyperthyroidism, hypoglycemia, hyperadrenalism, hyperparathyroidism
Metabolic	Vitamin B_{12} deficiency, folate deficiency, porphyria, hypoxemia, hypercalcemia
Neurologic	Neoplasm, vestibular dysfunction, encephalitis, trauma (contusion or hematoma), MS, temporal lobe epilepsy, migraine
Infectious	Cerebral (meningitis, HIV, syphilis) or systemic
GI	Gastritis, esophageal spasm
Substance-Induced	Intoxication (caffeine, cannabis, amphetamines, cocaine, thyroid replacement, OTC for colds/decongestants, steroids), withdrawal (benzodiazepines, alcohol)

Medical Workup of Anxiety Disorder

- only proceed with medical workup as clinically indicated
- routine screening: vitals, physical exam, CBC, electrolytes, thyroid function test, glucose, ECG
- additional screening: extended electrolytes, vitamin B_{12}, beta-HCG, folate, chest x-ray, any other tests as per DDx in Table 2

Risk Factors for the Development of Anxiety Disorders

- biological
  - endocrine disorders (i.e. hyperthyroidism), respiratory conditions (i.e. asthma), CNS conditions (i.e. temporal lobe epilepsy), substances/medications (i.e. excessive stimulant use), chronic medical illness
  - personal or family history of anxiety or mood disorder
  - XX>XY chromosomes
- psychological
  - current stress, early childhood adversity or trauma, early parental loss, parental factors

Panic Disorder

DSM-5 DIAGNOSTIC CRITERIA FOR PANIC DISORDER

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. recurrent unexpected panic attacks; a panic attack is an abrupt surge of intense fear or intense discomfort that reaches a peak within minutes, and during which time four (or more) of the following symptoms occur
   - palpitations, pounding heart, or accelerated heart rate
   - sweating
   - trembling or shaking
   - sensations of shortness of breath or smothering
   - feelings of choking
   - chest pain or discomfort
   - nausea or abdominal distress
   - feeling dizzy, unsteady, light-headed, or faint
   - chills or heat sensations
   - paresthesias (numbness or tingling sensations)

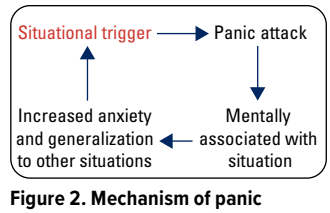

Figure 2. Mechanism of panic attacks

- derealization (feelings of unreality) or depersonalization (being detached from oneself)
- fear of losing control or "going crazy"
- fear of dying

B. at least one of the attacks has been followed by 1 mo (or more) of one or both of the following:
- persistent concern or worry about additional panic attacks or their consequences
- a significant maladaptive change in behaviour related to the attacks

C. the disturbance is not attributable to the physiological effects of a substance or another medical condition

D. the disturbance is not better explained by another mental disorder

Epidemiology
- lifetime prevalence: 5% (one of the top five most common reasons to see a family physician); M:F=1:2-3
- onset: average early-mid 20s, familial pattern
- comorbidities: depression, agoraphobia, medical comorbidity

Treatment
- pharmacological and psychological treatment together can be very effective
- psychological
  - CBT: exposure (graduated exposure to unpleasant sensations of arousal associated with a panic attack for experiential disconfirmation of their fears), cognitive restructuring (addressing underlying beliefs regarding the panic attacks), relaxation techniques (visualization, box-breathing), psychoeducation
- pharmacological (first line agents)
  - SSRIs: fluoxetine, citalopram, escitalopram, paroxetine, sertraline, fluvoxamine
  - SNRI: venlafaxine extended release
  - with SSRI/SNRIs, start with low doses and titrate up as tolerated
  - anxiety disorders often require treatment at higher doses for a longer period of time than depression (full response may take up to 12 wk)
  - treat for up to 1 yr after symptoms resolve to avoid relapse
  - explain expected adverse effects prior to initiation of therapy to prevent non-adherence
  - other antidepressants: (mirtazapine, TCAs)
  - benzodiazepines considered 2nd line (short-term, lowest effective dose, helpful while titrating antidepressant)

Prognosis
- 85% can achieve good results, 10-20% continue with significant symptoms. Longer term, 65% achieve remission
- clinical course: chronic, but episodic with psychosocial stressors

Criteria for Panic Attack (≥4)

STUDENTS FEAR the 3 Cs
Sweating
Trembling/shaking
Unsteadiness, dizziness
Depersonalization, Derealization
Excessive heart rate, palpitations
Nausea/abdominal distress
Tingling/numbness
Shortness of breath
Fear of dying, losing control, going crazy
3 Cs: **C**hest pain, **C**hills/hot flashes, **C**hoking

Duration typically 5-10 min

Panic Attack vs. Panic Disorder
- **Panic disorder** requires recurrent, unexpected panic attacks + fear of another panic attack
- **Panic attacks** can occur in the context of many different disorders

Starting Medication for Anxiety
Start low, go slow, aim high and explain symptoms to expect prior to initiation of therapy to prevent non-adherence due to side effects

Agoraphobia

DSM-5 DIAGNOSTIC CRITERIA FOR AGORAPHOBIA
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. marked fear or anxiety about two (or more) of the following five situations:
- using public transportation
- being in open spaces
- being in enclosed places
- standing in line or being in a crowd
- being outside of the home alone

B. the individual fears or avoids these situations because of thoughts that escape might be difficult or help might not be available in the event of developing panic-like symptoms or other incapacitating or embarrassing symptoms

C. the agoraphobic situations almost always provoke fear or anxiety

D. the agoraphobic situations are actively avoided, require the presence of a companion, or are endured with intense fear or anxiety

E. the fear or anxiety is out of proportion to the actual danger posed by the agoraphobic situations and to the sociocultural context

F. the fear, anxiety, or avoidance is persistent, typically lasting ≥6 mo

G. the fear, anxiety, or avoidance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning

H. if another medical condition is present, the fear, anxiety, or avoidance is clearly excessive

I. the fear, anxiety, or avoidance is not better explained by the symptoms of another mental disorder and are not related exclusively to obsessions, perceived defects or flaws in physical appearance, reminders of traumatic events, or fear of separation

Note: agoraphobia is diagnosed irrespective of the presence of panic disorder. If an individual's presentation meets criteria for panic disorder and agoraphobia, both diagnoses should be assigned

Treatment
- as per specific panic disorder

Generalized Anxiety Disorder

DSM-5 DIAGNOSTIC CRITERIA FOR GENERALIZED ANXIETY DISORDER

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. excessive anxiety and worry (apprehensive expectation), occurring more days than not for at least 6 mo, about a number of events or activities (such as work or school performance)
B. the individual finds it difficult to control the worry
C. the anxiety and worry are associated with three (or more) of the following six symptoms (with at least some symptoms having been present for more days than not for the past 6 mo)
    1. restlessness or feeling keyed up or on edge
    2. being easily fatigued
    3. difficulty concentrating or mind going blank
    4. irritability
    5. muscle tension
    6. sleep disturbance (difficulty falling or staying asleep, or restless, unsatisfying sleep)
D. the anxiety, worry, or physical symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning
E. the disturbance is not attributable to the physiological effects of a substance or another medical condition
F. the disturbance is not better explained by another mental disorder

Criteria for GAD (≥3)

C-FIRST
Concentration issues
Fatigue
Irritability
Restlessness
Sleep disturbance
Tension (muscle)

Epidemiology

- 1 yr prevalence: 1-4%, lifetime prevalence 6%; M:F=1:2
    - 8% of all who seek primary care treatment (WHO)
    - in primary care: 70% initially present with physical symptoms as main concern
- bimodal age of onset: before 20 or middle adulthood

Source: Depression and other common mental disorders: Global health estimates. Geneva: World Health Organization, 2017.

Treatment

- lifestyle: avoid caffeine and EtOH, sleep hygiene
- psychological: CBT (cognitive restructuring), muscle relaxation techniques, mindfulness
- biological
    - 1st line: SSRIs (escitalopram, sertraline, paroxetine), SNRIs (venlafaxine XR, duloxetine), pregabalin
    - benzodiazepines considered 2nd line (short-term, lowest effective dose, helpful while titrating antidepressant)
    - β-blockers not recommended

Prognosis

- good with treatment
- depends on pre-morbid personality functioning, stability of relationships, work, and severity of environmental stress

Social Anxiety

- definition: marked and persistent (>6 mo) fear of social or performance situations in which one is exposed to unfamiliar people or to possible scrutiny by others. They fear that they will be negatively evaluated in a way that may be humiliating, embarrassing, or lead to rejection (e.g. public speaking, initiating or maintaining conversation, dating, eating in public)
- situations are avoided or endured with intense anxiety and causes significant distress or impairment in functioning
- lifetime prevalence 8-12%; M:F ratio approximately equal

Phobic Disorders

Specific Phobias

- definition: marked and persistent (>6 mo) fear that is excessive or unreasonable, cued by presence or anticipation of a specific object or situation
- lifetime prevalence 10-13%; M:F ratio variable
- types: animal/insect, environment (e.g. heights, storms), blood/injection/injury, situational (e.g. airplane, closed spaces), other (e.g. loud noise, clowns), multiple fears

Diagnostic Criteria for Phobic Disorders

- marked fear/anxiety about a specific object/situation
- exposure to stimulus almost invariably provokes an immediate fear/anxiety response; may present as a panic attack
- phobic object/situation is actively avoided or endured with intense anxiety.
- fear/anxiety out of proportion to actual danger/sociocultural context and persistent (lasting 6 mo or more)
- person recognizes fear as excessive or unreasonable
- significant impact on daily routine, occupational/social functioning and/or marked distress

Treatment
- psychological: psychoeducation, CBT (focusing on both in vivo and virtual exposure therapy, gradually facing feared situations)
- biological: minimal role for medications

Obsessive-Compulsive and Related Disorders

Obsessive-Compulsive Disorder

DSM-5 DIAGNOSTIC CRITERIA FOR OBSESSIVE-COMPULSIVE DISORDER
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. presence of obsessions, compulsions, or both
   - obsessions are defined by (1) and (2)
     1. recurrent and persistent thoughts, urges, or images that are experienced, at some time during the disturbance, as intrusive and unwanted, and that in most individuals cause marked anxiety or distress
     2. the individual attempts to ignore or suppress such thoughts, urges, or images, or to neutralize them with some other thought or action (i.e. by performing a compulsion)
   - compulsions are defined by (1) and (2)
     1. repetitive behaviours (e.g. hand washing, ordering, checking) or mental acts (e.g. praying, counting, repeating words silently) that the individual feels driven to perform in response to an obsession or according to rules that must be applied rigidly
     2. the behaviours or mental acts are aimed at preventing or reducing anxiety or distress, or preventing some dreaded event or situation; however, these behaviours or mental acts are not connected in a realistic way with what they are designed to neutralize or prevent, or are clearly excessive

B. the obsessions or compulsions are time-consuming (e.g. take >1 h/d) or cause clinically significant distress or impairment in social, occupational, or other important areas of functioning

C. the obsessive-compulsive symptoms are not attributable to the physiological effects

D. the disturbance is not better explained by the symptoms of another mental disorder

- **specifiers**: with good or fair insight, with poor insight, with absent insight/delusional beliefs, tic-related
- **most common obsessions**: contamination fear, pathological doubts, harm (sex, aggression), somatic dysfunctions, need for symmetry, religious
- **most common compulsions**: checking, washing, repeating, ordering, counting, need to ask, and hoarding
- rituals serve to counteract the anxiety induced by the obsessive thoughts

Epidemiology
- lifetime prevalence 3%
- mean age of onset: 20 yr; onset after 35 yr rare
- rate of OCD in first-degree relatives is higher than in the general population
- common comorbidities: anxiety disorders (>75%), depressive or bipolar disorder (>60%), obsessive-compulsive PD, tic disorders, substance use disorder, body dysmorphic disorder, trichotillomania, and excoriation disorder

Risk Factors
- etiology unknown but linked with:
  - neurological abnormalities: neurological dysfunction (brain injury, Sydenham's or Huntington's chorea), abnormal EEG, and abnormal evoked auditory potentials
  - family history of OCD or Tourette's disorder
  - paediatric autoimmune neuropsychiatric disorders associated with streptococcal infection (PANDAS) in children following group A β-streptococcal infection; also linked to D8/17 antigen positivity
  - social isolation, physical abuse, negative emotionality

Treatment
- CBT: ERP which involves exposure to feared situations using various techniques (e.g. imaginal exposure, systematic desensitization, flooding) with the addition of preventing the compulsive behaviours; cognitive strategies include challenging underlying beliefs
- pharmacotherapy: SSRIs (12-16 wk potential delay until response, higher therapeutic dosages than used for depression), clomipramine; adjunctive antipsychotics (risperidone, aripiprazole) for refractory OCD
- neurosurgery or neurostimulation: anterior cingulotomy for severe refractory OCD, two techniques: radiofrequency thermolesion and gamma knife capsulotomy or cingulotomy (50-70% response rate); ECT (particularly for those with comorbid severe depression)

Prognosis
- may be refractory and chronic with waxing and waning symptoms (<20% remission rate without treatment)

Related Disorders

Body Dysmorphic Disorder
- preoccupation with ≥1 perceived flaws in physical appearance not observed by others
- repetitive behaviours (e.g. mirror checking, excessive grooming, skin picking, or reassurance seeking) or mental acts (e.g. comparing self to others) related to appearance
- ± muscle dysmorphia
- causes clinically significant distress or functional impairment
- rule out eating disorder
- mean age of onset: 15 y/o
- symptoms tend to be chronic; high rate of suicidal ideation and attempts; comorbidity with MDD, social anxiety disorder, and OCD

Hoarding Disorder
- persistent difficulty discarding possessions regardless of actual value
- feels the need to save items, discarding creates distress
- results in possessions cluttering/compromising active living areas (may be uncluttered with 3rd party intervention, i.e. family member, cleaners, authorities)
- causes clinically significant distress or functional impairment
- rule out brain injury, cerebrovascular disease, Prader-Willi syndrome, OCD, MDD (low energy), psychotic disorder (delusions), neurocognitive disorder, ASD (restricted interests)
- tends to begin in teens and worsens over time, more common in older populations, large genetic component

Trichotillomania (Hair-Pulling Disorder)
- recurrent pulling out own hair resulting in hair loss (usually involves scalp, eyebrows, or eyelashes but may include other hair)
- repeated attempts to stop or decrease hair pulling
- causes clinically significant distress or functional impairment
- rule out dermatological condition, body dysmorphic disorder
- treatment: CBT (habit reversal training), SSRIs, 2nd gen. antipsychotics, N-acetylcysteine, or lithium

Excoriation (Skin-Picking) Disorder
- recurrent skin picking resulting in lesions
- repeated attempts to stop or decrease skin picking
- causes clinically significant distress or functional impairment
- rule out scabies, substance use (e.g. cocaine), psychotic disorder (e.g. delusions, tactile hallucinations), body dysmorphic disorder, stereotypic movement disorder, non-suicidal self-injury
- treatment similar to trichotillomania (described above)

Trauma- and Stressor-Related Disorders

Post-Traumatic Stress Disorder

DSM-5 DIAGNOSTIC CRITERIA FOR POST-TRAUMATIC STRESS DISORDER
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association.

A. exposure to actual or threatened death, serious injury, or sexual violence in one (or more) of the following ways:
   1. directly experiencing the traumatic event(s)
   2. witnessing, in person, the event(s) as it occurred to others
   3. learning that the traumatic event(s) occurred to a close family member or close friend; in cases of actual or threatened death of a family member or friend, the event(s) must have been violent or accidental
   4. experiencing repeated or extreme exposure to aversive details of the traumatic event(s) (e.g. first responders collecting human remains: police officers repeatedly exposed to details of child abuse)

B. presence of one (or more) of the following intrusion symptoms associated with the traumatic event(s), beginning after the traumatic event(s) occurred:
   1. recurrent, involuntary, and intrusive distressing memories of the traumatic event(s)
   2. recurrent distressing dreams in which the content and/or affect of the dream are related to the traumatic event(s)
   3. dissociative reactions (e.g. flashbacks) in which the individual feels or acts as if the traumatic event(s) were recurring

The Trauma Triangle
The perpetrator
The victim
The rescuer

4. intense or prolonged psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event(s)
5. marked physiological reactions to internal or external cues that symbolize or resemble an aspect of the traumatic event(s)

C. persistent avoidance of stimuli associated with the traumatic event(s), beginning after the traumatic event(s) occurred, as evidenced by one or both of the following:
1. avoidance of or efforts to avoid distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s)
2. avoidance of or efforts to avoid external reminders (people, places, conversations, activities, objects, situations) that arouse distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s)

D. negative alterations in cognitions and mood associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by two (or more) of the following:
1. inability to remember an important aspect of the traumatic event(s)
2. persistent and exaggerated negative beliefs or expectations about oneself, others, or the world
3. persistent, distorted cognitions about the cause or consequences of the traumatic event(s) that lead the individual to blame himself/herself or others
4. persistent negative emotional state (e.g. fear, horror, anger, guilt, or shame)
5. markedly diminished interest or participation in significant activities
6. feelings of detachment or estrangement from others
7. persistent inability to experience positive emotions

E. marked alterations in arousal and reactivity associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by two (or more) of the following:
1. irritable behaviour and angry outbursts (with little or no provocation) typically expressed as verbal or physical aggression toward people or objects
2. reckless or self-destructive behaviour
3. hypervigilance
4. exaggerated startle response
5. problems with concentration
6. sleep disturbance (e.g. difficulty falling or staying asleep or restless sleep)

F. duration of the disturbance (criteria B, C, D, and E) is more than 1 mo

G. the disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning

H. the disturbance is not attributable to the physiological effects of a substance or another medical condition

- **specifiers**:
  - with dissociative symptoms (not attributable to physiologic effects of a substance or a medical condition); this could involve either depersonalization (persistent or recurrent experiences of feeling detached from, or as if one were an outside observer of one's mental processes or body) or derealization (persistent or recurrent experiences of unreality of surroundings)
  - with delayed expression: the full diagnostic criteria are not met until 6 mo after the event

Criteria for Post-Traumatic Stress Disorder

TRAUMA
Traumatic event
Re-experience the event
Avoidance of stimuli associated with the trauma
Unable to function
More than a Month
Arousal increased
+ negative alterations in cognition and mood

Epidemiology

- lifetime prevalence in Canada is 9%; onset in mid-late 20s
- 75% have another comorbid psychiatric disorder; increased risk of suicide 2-3x
- high rates of chronic pain, sleep problems, sexual dysfunction, cognitive dysfunction
- prevalence F:M = 2:1
- most common forms of trauma: unexpected death of someone close, sexual assault, serious illness or injury to someone close, physical assault by partner or caregiver
- risk factors: severity, duration, and proximity to trauma
- differential diagnosis: bipolar disorder, borderline personality disorder, acute stress disorder (3 d-1 mo after trauma)

Treatment

- trauma therapy, CBT
  - stage 1 - safety and stabilization: emotional regulation techniques (i.e. breathing, relaxation) to help build coping skills, medications for PTSD, manage substance use
  - stage 2 - remembrance and mourning: exposure to traumatic memories and work through distorted thoughts, relational patterns, and grief
  - stage 3 - reconnection and integration: exposure therapy, etc. create a new future, new relationships, strengthen identity
- early intervention via psychological support (not de-briefing)
- psychotherapy: CBT, DBT, supportive, eye movement desensitization and reprocessing (EMDR)
- biological
  - first line: fluoxetine, paroxetine, sertraline, venlafaxine XR (50-80% response with residual symptoms is common)
  - prazosin (for treating disturbing dreams and nightmares)
  - benzodiazepines (for acute anxiety; use with extreme caution)
  - adjunctive atypical antipsychotics (risperidone, olanzapine)

Prognosis and Complications
- substance use disorder, relationship difficulties, depression, impaired social and occupational functioning disorders, personality disorders
- 50% of patients with PTSD have complete recovery within 3 mo, symptoms tend to diminish with age

Adjustment Disorder

Definition
- a diagnosis encompassing patients who have difficulty coping with a stressful life event or situation and develop acute, often transient, emotional or behavioural symptoms that resemble less severe versions of other psychiatric conditions

Acute Stress Disorder
- May be a precursor to PTSD
- Similar symptoms to PTSD
- Symptoms persist for 3d to 1 mo after exposure to a trauma

DSM-5 DIAGNOSTIC CRITERIA FOR ADJUSTMENT DISORDER
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. the development of emotional or behavioural symptoms in response to an identifiable stressor(s) occurring within 3 mo of the onset of the stressor(s)
B. these symptoms or behaviours are clinically significant as evidenced by either of the following:
   - marked distress that is in excess of what would be expected from exposure to the stressor
   - significant impairment in social or occupational (academic) functioning
C. the stress-related disturbance does not meet criteria for another mental disorder and is not merely an exacerbation of a pre-existing mental disorder
D. the symptoms do not represent normal bereavement
E. once the stressor (or its consequences) has terminated, the symptoms do not persist for more than an additional 6 mo

- **specifiers**: with depressed mood, with anxiety, with mixed anxiety/depression, with conduct disturbance, with mixed disturbance of conduct/emotions, unspecified

Classification
- types of stressors
  - single (e.g. termination of romantic relationship)
  - multiple (e.g. marked business difficulties and marital problems)
  - recurrent (e.g. seasonal business crises)
  - continuous (e.g. living in a crime-ridden neighbourhood)
  - developmental events (e.g. going to school, leaving parental home, getting married, becoming a parent, failing to attain occupational goals, retirement)

Epidemiology
- F:M=2:1, prevalence 2-8% of the population

Treatment
- brief psychotherapy: individual or group (particularly useful for patients dealing with unique and specific medical issues; e.g. colostomy or renal dialysis groups), crisis intervention
- biological: medications can be used to treat associated symptoms (insomnia, anxiety, or depression)
  - benzodiazepines may be used for those with significant anxiety symptoms (short-term, low-dose, regular schedule)

Bereavement

Clinical Features
- bereavement is a normal psychological and emotional reaction to a significant loss, also called grief or mourning
- length and characteristics of "normal" bereavement vary between individual cultures
- normal response: protest ➔ searching and acute anguish ➔ despair and detachment ➔ reorganization
- presence of the following symptoms may indicate abnormal grief/presence of MDD:
  - guilt about things other than actions taken or not taken by the survivor at the time of death
  - thoughts of death other than the survivor feeling that they would be better off dead or should have died with the deceased person; morbid preoccupation with worthlessness
  - marked psychomotor retardation; prolonged and marked functional impairment
  - hallucinatory experiences other than hearing the voice or transiently seeing the image of the deceased person
  - dysphoria that is pervasive and independent of thoughts or triggers of the deceased; absence of mood reactivity
- after 12 mo, if patient continues to yearn/long for the deceased, experience intense sorrow/emotional pain in response to the death, remain preoccupied with the deceased or with the circumstances of their death, then may start to consider a diagnosis of "persistent complex bereavement disorder"
- if a patient meets criteria for MDD, even in the context of a loss or bereavement scenario, they are still diagnosed with MDD

Risk Factors for Poor Bereavement Outcome
- Poor social supports
- Unanticipated death or lack of preparation for death
- Highly dependent relationship with deceased
- High initial distress
- Other concurrent stresses and losses
- Death of a child
- Pre-existing psychiatric disorders, especially depression and separation anxiety

Bereavement is associated with a significant increase in morbidity and mortality acutely following the loss, with effects seen up to 1 yr after

Treatment
- support and watchful waiting should be first line, as well as education and normalization of the grief process
- screen for increased alcohol, cigarette and drug use
- normal grief should not be treated with antidepressant or anti-anxiety medications as it is important to allow the person to experience the whole mourning process to achieve resolution
- psychosocial: grief therapy (individual or group) is indicated for those needing additional support or experiencing complex grief/bereavement or significant MDD
- pharmacotherapy: if MDD present, past history of mood disorders, or severe symptoms

Loneliness is the most common symptom that continues to persist in normal bereavement and may last several years

Neurocognitive Disorders

Delirium

- see Neurology, N21

DSM-5 DIAGNOSTIC CRITERIA FOR DELIRIUM
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. a disturbance in attention (i.e. reduced ability to direct, focus, sustain, and shift attention) and awareness (i.e. reduced orientation to the environment)
B. the disturbance develops over a short period of time (usually hours to a few days), represents a change from baseline attention and awareness, and tends to fluctuate in severity during the course of a day
C. an additional disturbance in cognition (e.g. memory deficit, disorientation, language, visuospatial ability, or perception)
D. the disturbances in criteria A and C are not better explained by another preexisting, established, or evolving neurocognitive disorder and do not occur in the context of a severely reduced level of arousal (e.g. coma)
E. there is evidence from the history, physical exam, or laboratory findings that the disturbance is a direct physiological consequence of another medical condition, substance intoxication or withdrawal (i.e. due to a drug of abuse or to a medication), or exposure to a toxin, or is due to multiple etiologies

Clinical Features and Assessment
- common symptoms
  - disturbance of attention: distractibility, disorientation (time, place, rarely person)
  - sleep/wake disturbance (daytime sedation, nighttime agitation or wakefulness)
  - psychotic-like symptoms such as delusions, misinterpretations, illusions, and hallucinations (visual hallucinations are organic until proven otherwise)
  - affective symptoms (anxiety, fear, depression, irritability, anger, euphoria, apathy)
  - shifts in psychomotor activity (groping/picking at clothes, attempts to get out of bed when unsafe, sudden movements, sluggishness, lethargy)
- **Note**: fluctuation/major changes in all of the above over the course of the day are to be expected - so collateral history is important
- hyperactive 30% vs. hypoactive 24% vs. mixed level of activity 46%
- Folstein Mini Mental Status Exam or the Montreal Cognitive Assessment (MoCA) are helpful to assess baseline of altered mental state (i.e. score will improve as symptoms resolve)

Risk Factors
- polypharmacy particularly involving psychoactive drugs, anticholinergics, and serotonergic medications (e.g. Cogentin, Benadryl®, benzodiazepines, opioids, and corticosteroids)
- infection, dehydration, malnutrition, immobility (including use of restraints), and use of bladder catheters
- hospitalization (incidence 10-56%); frail and surgical patients are at the greatest risk
- previous delirium
- nursing home residents (incidence 60%)
- old age (especially males)
- severe illness (e.g. cancer, AIDS)
- recent anesthesia or surgery (e.g. emergency hip fracture surgery, cardiac surgery)
- brain vulnerability: pre-existing neurologic or neurocognitive disorder, substance use disorder, past psychiatric illness

Assessment/Investigations
- history: if a patient has delirium they may not be able to provide a reliable history, collateral history required; use beside clinical assessment tools such as the Confusion Assessment Method (CAM) and bedside tests to assess for attention, memory, visuospatial and executive function, and orientation
- standard bloodwork: CBC and differential, electrolytes (including Ca^{2+}, Mg^{2+}, and PO_4^{3-}), glucose, BUN, Cr, TSH/T4, LFTs, vitamin B_{12}, folate, albumin; if indicated, order blood cultures and infectious serologies (HIV, VDRL, Hep B/C)

Confusion Assessment Method (CAM) for Diagnosis of Delirium

Highly sensitive and specific method to diagnose delirium
Part 1: an assessment instrument that screens for overall cognitive impairment
Part 2: includes four features found best able to distinguish delirium from other cognitive impairments

Need (1) + (2) + (3 or 4)
(1) Acute onset and fluctuating course
(2) Inattention
(3) Disorganized thinking
(4) Altered level of consciousness - hyperactive or hypoactive

Etiology of Delirium

I WATCH DEATH
Infectious (encephalitis, meningitis, urinary tract infection, pneumonia)
Withdrawal (alcohol, barbiturates, benzodiazepines)
Acute metabolic disorder (electrolyte imbalance, hepatic or renal failure)
Trauma (head injury, postoperative)
CNS pathology (stroke, hemorrhage, tumour, seizure disorder, Parkinson's)
Hypoxia (anemia, cardiac failure, pulmonary embolus)
Deficiencies (vitamin B_{12}, folic acid, thiamine)
Endocrinopathies (thyroid, glucose, parathyroid, adrenal)
Acute vascular (shock, vasculitis, hypertensive encephalopathy)
Toxins: substance use, sedatives, opioids (especially morphine), anesthetics, anticholinergics, anticonvulsants, dopaminergic agents, steroids, insulin, glyburide, antibiotics (especially quinolones), NSAIDs
Heavy metals (arsenic, lead, mercury)

- standard imaging: CXR and CT head (indicated especially if focal neurological deficit, acute change in status, anticoagulant use, acute incontinence, gait abnormality, Hx of cancer); if indicated, abdominal x-ray for constipation and MRI head to detect or exclude subacute stroke and multifocal inflammatory lesions in patients with negative head CT
- standard urinalysis: urine dip; if indicated, urine drug screen, urine C&S
- if indicated: lumbar puncture and EEG (typical finding in delirium is generalized slowing, can also be used to rule out underlying seizures or post-ictal states as etiology)

Management

- goal is to treat the underlying causes of delirium while minimizing the physical and psychological distress to the patient
- step 1: identify and manage underlying cause
  - identify and treat underlying cause immediately
  - stop all non-essential medications
  - maintain nutrition, hydration, electrolyte balance, and monitor vitals
  - work to ensure regular bowel movements and skin care practices to prevent pressure ulcers
- step 2: optimize the environment
  - environment: quiet, well-lit, near window for cues regarding time of day
  - optimize hearing and vision; protect sleep (with medications if need be)
  - room near nursing station for closer observation; constant care if patient climbing out of bed, pulling out lines
  - family member present (or consider 1:1 sitter) for reassurance and re-orientation
  - frequent orientation: calendar, clock, reminders
  - avoid frequent changes of assigned nursing staff as well as room transfers
  - implement falls prevention strategies and enable safe mobility
  - physical restraints to maintain safety only if necessary; minimize lines and catheters
  - calm, supportive approach; therapeutic communication
- step 3: pharmacotherapy
  - low dose, high potency antipsychotics: haloperidol has the most evidence and can be given IV or IM; initiate Haldol® 0.5-1 mg IM/IV in elderly patients q1-2 h until agitation is under control for STAT or PRN situation; 0.5-2 mg PO q4-6 h - monitor for signs of EPS and QT prolongation
  - alternatives include risperidone, which is less sedating (0.25-0.5 mg PO BID; less sedating), olanzapine (more sedating, can be anticholinergic itself), quetiapine (if EPS sensitive but risk of hypotension; 6.25-50 mg PO qHS), aripiprazole (does not prolong QTc)
  - caution: all neuroleptics prolong the QT interval and decrease seizure threshold, thus increasing risk of cardiac arrhythmias and seizures, respectively; also, patients with Parkinson's disease or Lewy body dementia are particularly at high-risk of EPS
  - ECG to assess QT interval when considering treatment with an antipsychotic agent
  - benzodiazepines only used in alcohol/substance withdrawal delirium; otherwise, can worsen delirium (antipsychotics are not useful in EtOH or benzodiazepine withdrawal delirium); however, benzodiazepines should not be stopped if they are a long-standing medication or this may precipitate the delirium
  - try to minimize drugs with anticholinergic effects
  - note: antipsychotic medications are used in delirium to treat severe patient agitation, changing delirium from the hyperactive to hypoactive state; they do not treat the underlying "acute brain state" driving the delirium

Prognosis

- up to 50% 1 yr mortality rate after episode of delirium

Factors favouring psychosis over delirium

1. Auditory hallucinations that are structured and consistent
2. Personal or family history of psychosis
3. Gradual onset (unless substance induced)
4. History of a prodrome (insidious functional decline)

Factors favouring delirium over psychosis

1. Visual or tactile hallucinations
2. Acute onset
3. No previous history of psychosis
4. Sleep/wake changes
5. More global cognitive impairment
6. Recent medical illness/medication changes

Interventions for Preventing Delirium in Hospitalized Non-ICU Patients
Cochrane DB Syst Rev 2016:CD005563
Purpose: To assess effectiveness of interventions to prevent delirium in hospitalized patients in the non-ICU setting.
Methods: This study included RCTs on both pharmacological and non-pharmacological interventions for delirium in hospitalized patients in the non-ICU setting.
Results: 39 trials involving 16082 patients assessing 22 different interventions were included. Strong evidence was identified to support the use of multi-component interventions for the prevention of delirium. Multicomponent interventions include any intervention that uses non-pharmacological approaches to target multiple risk factors for delirium. Use of the Bispectral index to monitor anesthesia reduced incidence of postoperative delirium. Evidence to date does not support the use of cholinesterase inhibitors, antipsychotics, or melatonin to reduce incidence of delirium.

Major Neurocognitive Disorder (Dementia)

- see Neurology, N22

DSM-5 DIAGNOSTIC CRITERIA FOR MAJOR NEUROCOGNITIVE DISORDER

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. evidence of significant cognitive decline from a previous level of performance in one or more cognitive domains (complex attention, executive function, learning and memory, language, perceptual-motor, or social cognition) based on
   1. concern of the individual, a knowledgeable informant, or the clinician that there has been a significant decline in cognitive function;
      and
   2. a substantial impairment in cognitive performance, preferably documented by standardized neuropsychological testing or, in its absence, another quantified clinical assessment
B. the cognitive deficits interfere with independence in everyday activities (i.e. at a minimum, requiring assistance with complex IADLs such as paying bills or managing medications)
C. the cognitive deficits do not occur exclusively in the context of a delirium
D. the cognitive deficits are not better explained by another mental disorder (e.g. major depressive disorder, schizophrenia)
   - **Note**: if deficits do not interfere (as in B) and cognitive impairments are mild-moderate (as in A.2), this is considered "mild neurocognitive disorder;" see Neurology, N21

Specify whether due to:
- Alzheimer's disease
- frontotemporal lobar degeneration
- Lewy body disease
- vascular disease
- traumatic brain injury
- normal pressure hydrocephalus
- substance/medication use
- HIV infection
- Prion disease
- Parkinson's disease
- Huntington's disease
- another medical condition (e.g. nutritional deficiency)
- multiple etiologies
- unspecified
- also specify if mild, moderate or severe; major neurocognitive disorder diagnosis requires an impairment in functioning

Epidemiology
- prevalence increases with age: 5% in patients >65 yr, 35-50% in patients >85 yr
- probability of dementia in an older person with reported memory loss is estimated to be 60%
- prevalence is increased in people with Down's syndrome and head trauma
- Alzheimer's disease comprises >50% of cases; vascular causes comprise approximately 15% of cases (other causes of dementia neurocognitive disorder – see Neurology, N22)
- disease course: insidious onset, usually leading to death within 8-10 yr of first symptoms

The 7 As of Dementia
Amnesia: loss of memory
Aphasia: loss of language ability
Apraxia: loss of ability to carry out purposeful movement
Agnosia: no longer recognizes things through the senses
Anosognosia: not knowing what one does not know
Apathy: loss of Initiative
Altered perception

Subtypes
- with or without behavioural disturbance (e.g. wandering, agitation)
- early-onset: <65 yr, late-onset: >65 yr

Assessment and Investigations (to rule out reversible vauses)
- history: consider the 7 A's of dementia, significant changes in ADLs and IADLS, medication compliance and substance use, risk factors for dementia and delirium, mood/anxiety and psychotic symptoms, screen for non-Alzheimer's dementias, assess safety and consent/capacity issues
- cognitive tests (e.g. MMSE, Rowland Universal Dementia Assessment Scale, Frontal Assessment Battery, MoCA)
- MoCA 18-25 suggestive of mild NCD, <18 suggestive of major NCD; beware of many false positives)
- standard "neurocognitive work-up": see *Delirium*, PS23
- as indicated: VDRL, HIV, LP, CXR, EEG, SPECT, head CT, or MRI
- indications for head imaging: same as for delirium, plus: age <60, rapid onset (unexplained decline in cognition or function over 1-2 mo), dementia of relatively short duration (<2 yr), recent significant head trauma, unexplained neurological symptoms (new onset of severe headache/seizures), bleeding disorder or use of anticoagulants, Hx of cancer, suspicions of normopressure hydrocephalus, and presence of unsuspected cerebrovascular disease would change management

The "Mini Cog" Rapid Assessment
3 word immediate recall
Clock drawn to "10 past 11"
3 word delayed recall

Management
- see Neurology, N22 for further management
- treat underlying medical problems and prevent new ones (e.g. treatment of hypertension and B_{12} deficiency)
- discontinue cognitively impairing medications (e.g. anticholinergic, benzodiazepines, non-benzodiazepine ("Z-drugs"))
- provide orientation cues for patient (e.g. clock, calendar)
- provide education and support for patient and family (e.g. day programs, respite care, support groups, home care)
- consider power of attorney/living will and long-term care plan (nursing home)
- inform Ministry of Transportation about patient's inability to drive safely
- consider pharmacological therapy
- to slow AD:
  - cholinesterase inhibitors (donepezil (Aricept®, 5-10 mg once daily), rivastigmine, galantamine) for mild to severe disease
  - NMDA receptor antagonist (memantine 5 mg once daily to 10 mg BID) for moderate to severe disease
- to manage AD:
  - low-dose atypical antipsychotics such as olanzapine (2.5-10 mg/d), quetiapine (25-200 mg/d), or risperidone (0.25-3 mg/d) for severe behavioural disturbances
  - trazodone (25-100 mg) can be used for night-time agitation
- to treat comorbid psychiatric conditions:
  - antidepressants such as escitalopram can be used for depressive episodes
  - "start low and go slow" (effective doses can be 1/3 to 1/2 that of regular adult age patients); reassess pharmacological therapy every 3 mo

Table 3. Comparison of Dementia, Delirium, and Cognitive Impairment Associated with Depression

	Dementia/Major Neurocognitive Disorder	Delirium	Cognitive Impairment Associated with Depression
Onset	Gradual/step-wise decline	Acute (usually hours to days)	Subacute
Duration	Months-years	Days-weeks	Variable
Natural History	Progressive Usually irreversible	Fluctuating, reversible high morbidity/mortality in the elderly	Recurrent Partially reversible
Level of Consciousness	Normal	Fluctuating between (agitation) hyperactive and stupor (hypoactive) (over 24 h)	Normal
Attention	Not initially affected	Decreased (wandering, easy distraction)	Difficulty concentrating
Orientation	Intact initially	Impaired (usually to time and place), fluctuates	Intact
Behaviour	Disinhibition, impairment in ADL/IADL, personality change, loss of social graces	Potential for agitation/retardation (even severe)	Anhedonia, decreased/increased sleep/eating, agitation/retardation
Psychomotor	Normal	Fluctuates between extremes	Slowing or agitation
Sleep Wake Cycle	Fragmented sleep at night	Reversed sleep wake cycle	Early morning awakening
Mood and Affect	Labile, anxiety or depression are common in the early stages	Anxious, irritable, fluctuating or apathetic, withdrawn	Depressed, pervasive
Cognition	Decreased executive functioning, paucity of thought	Fluctuating	May appear to be impaired/slowed
Memory Loss	Recent, eventually remote Typically, low insight	Marked recent	Recent More likely to complain
Language	Agnosia, aphasia, decreased comprehension, repetition, speech (echolalia, palilalia)	Dysnomia, dysgraphia, speech rambling, irrelevant, incoherent, subject changes	Not affected
Delusions	Compensatory	Nightmarish and poorly formed	Nihilistic, somatic
Hallucinations	Variable	Visual common	Less common; if present, auditory predominates
Quality of Hallucinations	Vacuous/bland	Frightening/bizarre	Self-deprecatory
Medical Status	Variable	Acute illness, drug toxicity	Rule out systemic illness, medications

Most Common Causes of Dementia

- **Alzheimer's disease (up to 50-60%):** predominantly memory and learning issues, insidious onset/gradual progression
- **Frontotemporal degeneration (5%):** language type (early preservation), behavioural type (apathy/disinhibition/self-neglect); more common among those with dementia that has onset before age 65; progressive
- **Lewy body disease (up to 25%):** early changes in executive and attention, may fluctuate, well-formed visual hallucinations (e.g. rabbits), autonomic impairment (falls, hypotension), Parkinson's type EPS that does not respond well to pharmacotherapy and follows >1 yr after cognitive decline, fluctuating degree of cognitive impairment, sleep disturbances
- **Vascular disease (15-30%):** vascular risk factors, focal neurological signs, abrupt onset, stepwise progression, executive dysfunction > memory impairment, personality and mood changes (loss of motivation)
- **Normal pressure hydrocephalus:** abnormal gait ("magnetic gait"), early incontinence, rapidly progressive; dilated ventricles on imaging

Substance-Related and Addictive Disorders

Overview

- substance use disorder (SUD): a neurobiological disorder involving compulsive drug seeking and drug taking, despite adverse consequences, with loss of control over drug use (think issues with the "3 Cs": compulsive, consequences, control)
- it is possible to have a substance use disorder without physiological dependence (i.e. withdrawal syndrome or tolerance), dependence is the hallmark of substance use disorders and comes in the following forms:
  - behavioural: substance-seeking activities and pathological use patterns
  - physical: physiologic withdrawal effects without use or tolerance
  - cognitive: continuous or intermittent cravings for the substance to avoid dysphoria or to attain drug state
- drug misuse: drug use that deviates from the approved social or medical pattern, usually causing impairment or disruption to function in self or others
- these disorders are usually chronic with a relapsing and remitting course
- there are 10 separate classes of substances identified in the DSM-5: alcohol; caffeine; cannabis hallucinogens (PCP or similarly acting arylcyclohexylamines, and other hallucinogens); inhalants; opioids; sedatives, hypnotics, and anxiolytics; stimulants (amphetamine-type substances, cocaine, and other stimulants); tobacco; and other (or unknown) substances
- whereas substance use disorders imply addiction to substances, addictive disorders include process (behavioural) addictions such as gambling

Epidemiology

- the lifetime prevalence of SUD in Canada is 21.6% lifetime and 10.1 % for the last 12 mo; for alcohol use disorder it is 18.1% and 3.2%; for cannabis use disorder 6.8% and 1.3% and for other substances, 4.0% and 0.7%, respectively
- 47% of those with substance use disorder have mental health problems
- 29% of those with a mental health disorder have a substance use disorder
- 47% of those with schizophrenia and 25% of those with an anxiety disorder have a substance use disorder

Etiology

- almost all drugs (and activities) related to dependence increase dopamine in the nucleus accumbens, an action that contributes to their euphoric properties and, with repeated use, to their ability to change signaling pathways in the brain's reward system
- substance use disorders arise from multifactorial interactions between genes (personality, neurobiology) and environment (low socioeconomic status, substance-using peers, adverse childhood or traumatic experiences, social isolation, systemic racism, and chronic stress)
- certain comorbid conditions may also predispose individuals to a substance use disorder (e.g. mental illness, chronic disease, acute and chronic pain)
- environmental factors play a significant role in the exposure to the substance. For instance, the over prescription of opioids for pain in North America played a major role in the development of the opioid use disorder crisis

Diagnosis

- each specific substance is addressed as a separate use disorder and diagnosed utilizing the same overarching criteria (e.g. a single patient may have moderate alcohol use disorder, and a mild stimulant use disorder)
- testing for illicit drugs is most commonly done on urine or blood samples
  - serum toxicology screen measures recent alcohol consumption but has no relation to the diagnosis of alcohol use disorder
  - toxicology may be helpful in differentiating withdrawal from other mental disorders
  - urine drug screens are useful for detecting recent drug use, but not for diagnosing drug use disorders
- substance use disorders are measured on a continuum from mild to severe based on the number of criteria met within 12 mo
  - mild: 2-3
  - moderate: 4-5
  - severe: 6 or more
- criteria for substance use disorders (**PEC WITH MCAT**)
  - use despite **P**hysical or psychological problem (e.g. alcoholic liver disease or cocaine related nasal problems)
  - failure to fulfill **E**xternal roles at work/school/home
  - **C**raving or a strong desire to use substance
  - **W**ithdrawal
  - continued use despite **I**nterpersonal problems
  - **T**olerance: needing to use more substance to get same effect
  - use in physically **H**azardous situations
  - **M**ore substance used or for longer period than intended
  - unsuccessful attempts to **C**ut down
  - **A**ctivities given up due to substance
  - excessive **T**ime spent on using or finding substance

Table 4. Substance Symptomatology

	Drugs	Symptoms of Intoxication	Symptoms of Withdrawal
CNS Depressants	Alcohol, opioids, barbiturates, benzodiazepines, GHB	Euphoria, slurred speech, disinhibition, confusion, poor coordination, coma (severe)	Anxiety, anhedonia, tremor, seizures, insomnia, psychosis, delirium, death
Stimulants	Amphetamines, methylphenidate, MDMA, cocaine	Euphoria, mania, psychomotor agitation, anxiety, psychosis (especially paranoia), insomnia, cardiovascular complications (stroke, MI, arrhythmias), seizure	'Crash', craving, dysphoria, suicidality
Hallucinogens	LSD, mescaline, psilocybin, PCP, ketamine, ibogaine, salvia	Distortion of sensory stimuli and enhancement of feelings, psychosis (++ visual hallucinations), delirium, anxiety (panic), poor coordination	Usually absent

Questions to Characterize Substance Use and Risk Assessment (THE WATER)

- When was the last **T**ime you used?
- **H**ow long can you go without using?
- Have you **E**xperienced medical or legal consequences of your use?
- Any previous attempts to cut down or quit, and did you experience any **W**ithdrawal symptoms?
- How has your substance use **A**ffected your work, school, relationships?
- Are there any **T**riggers that you know will cause you to use?
- Substances can be very **E**xpensive, how do you support your drug use?
- By what **R**oute (oral ingestion, inhalation (snorting), smoking, IV) do you usually use?

General Approach to Assessment

- a comprehensive evaluation should inquire about drug history including names of substances used, amount, frequency, duration, routes, last use, injection drug use, needle sharing, symptoms of withdrawal, consequences of use (medical, social, or personal), previous treatment programs and medical (e.g. HIV, Hepatitis B and C, chronic pain), psychiatric (e.g. mood and anxiety disorders), and social history (e.g. family and housing arrangements, any child safety concerns)
- ask about more socially accepted substances (e.g. nicotine, alcohol) before asking about use of cannabis, misuse of prescription medicines, and about illicit drugs
- obtaining collateral history is recommended as well as evaluating patient insight into the problem

Lab Testing
- urine, saliva, sweat, and hair can be tested for the presence of drugs
- urine is most commonly used due to ease of collection and adequate sensitivity and specificity, but it does not reflect serum concentrations
- proper urine drug testing involves an initial screening test (qualitative) followed by confirmatory testing for substances with positive screening results
- most confirmatory tests use gas or high-performance liquid chromatography
- post-ingestion window of detection with urine test: alcohol (7-12 h), amphetamine (48 h), barbiturates (1-21 d), short-acting benzodiazepine (72 h), long-acting benzodiazepine (30 d), cocaine (12-72 h), morphine (48-72 h), methadone (72 h), Oxycodone (2-4 d), PCP (8 d), cannabis (3 d for single use to >30 d for heavy users)
- limitations: negative tests cannot rule out substance use, and positive results cannot determine how much or frequency of use

General Approach to Treatment
- approach must be appropriate to the patient's current state of change (see Public Health and Preventive Medicine, *Health Promotion Strategies*, PH11)
- patients will only change when the pain of change appears less than the pain of staying the same
- provider can help by providing psychoeducation (emphasize neurobiologic model of addiction), motivation, and hope
- principles of motivational interviewing (see *Psychotherapy*, PS50)
  - non-judgmental stance
  - space for patient to talk and reflect
  - offer accurate empathic reflections back to patient to help frame issue
- encourage and offer referral to evidence based services
  - social: 12-step programs (alcoholics anonymous, narcotics anonymous), family education, and support
  - psychological therapy: addiction counselling, MET, CBT, contingency management, group therapy, family therapy, marital counselling
  - medical management (differs depending on substance): acute detoxification, pharmacologic agents to aid maintenance
- harm reduction whenever possible: safe-sex practices, avoid driving while intoxicated, avoid substances with child care, safe needle practices/exchange, pill-testing kits, reducing tobacco use
- comorbid psychiatric conditions: many will resolve with successful treatment of the substance use disorder but patients who meet full criteria for another disorder should be treated for that disorder with psychological and pharmacologic therapies
- always consider duty to inform Ministry of Transportation for risk of driving or operating other vehicles

Nicotine

- see Family Medicine, FM13

Alcohol

- see Family Medicine, FM15 and Emergency Medicine, ER54

History
- Validated screening questionnaire for alcohol use disorders
  - **C** ever felt the need to **C**ut down on your drinking?
  - **A** ever felt **A**nnoyed at criticism of your drinking?
  - **G** ever feel **G**uilty about your drinking?
  - **E** ever need a drink first thing in the morning (**E**ye opener)?
    - for men, a score of ≥2 is a positive screen; for women, a score of ≥1 is a positive screen
    - if positive CAGE, then assess further to distinguish between problem drinking and alcohol use disorder

Canada's Low-Risk Alcohol Drinking Guidelines

Moderate Drinking		
Men: 3 or less/d (≤15/wk)	Women: 2 or less/d (≤10/wk)	Elderly: 1 or less/d

Biochemical Markers of Prolonged Alcohol Use
- elevated liver function tests (AST, ALT, GGT), MCV, and carbohydrate-deficient transferrin (CDT)
- AST:ALT ratio >2:1 and elevated GGT are suggestive of alcohol use

Confabulations: the fabrication of imaginary experiences to compensate for memory loss

Make sure to ask about other alcohols: mouthwash, rubbing alcohol, methanol, ethylene glycol, aftershave (may be used as a cheaper alternative)

A "Standard Drink" (SD)
Spirit (40%): 1.5 oz. or 43 mL
Table Wine (12%): 5 oz. or 142 mL
Fortified Wine (18%): 3 oz. or 85 mL
Regular Beer (5%): 12 oz. or 341 mL
OR
1 pint of beer = 1.5 SD
1 bottle of wine = 5 SD
1 "mickey" = 8 SD (375 mL)
"26-er" = 17 SD (750 mL)
"40 oz." = 27 SD

Alcohol Intoxication
- throughout Canada, the legal limit for impaired driving is a BAC ≥0.08% (≥80 mg/dL or 17.4 mmol/L) which is typically reached after 4 drinks in women and 5 drinks in men in a 2 h period
- most signs of intoxication are present at over >21.7 mmol/L (100 mg/dL): altered perception, impaired judgement, ataxia, hyper-reflexia, impaired coordination, changes in mood/personality, prolonged reaction time, and slurred speech
- respiratory depression and arrest can occur with >60 mmol/L (non-tolerant drinkers) and 90-120 mmol/L (tolerant drinkers)

Management of Alcohol Intoxication
- stabilize patient if there is reduced level of consciousness or vomiting; assess airways and respiratory function
- administer IV crystalloid fluids if evidence of volume depletion or shock; correct electrolytes and hypoglycemia
- monitor for signs of alcohol withdrawal following detoxification in patients with alcohol use disorder

Alcohol Withdrawal
- medical emergency: occurs within 12-48 h after prolonged heavy drinking and can be life-threatening
- ~50% of middle-class, functional individuals with alcohol use disorder have experienced alcohol withdrawal; 80% in hospitalized/homeless individuals
  - alcohol withdrawal can be described as having 4 stages, however not all stages may be experienced:
    - stage 1 (onset 4-12 h after last drink): "the shakes" tremor, sweating, agitation, anorexia, cramps, diarrhea, sleep disturbance, anxiety, insomnia, headache
    - stage 2 (onset 12-24 h): alcoholic hallucinosis: visual, auditory, olfactory, or tactile hallucinations
    - stage 3 (onset 12-48 h): alcohol withdrawal seizures, usually tonic-clonic, non-focal, and brief (can occur as early as 2 h after alcohol consumption)
    - stage 4 (onset 48-96 h): delirium tremens, confusion/disorientation, delusions, hallucinations, agitation, tremors, autonomic hyperactivity (diaphoresis, fever, tachycardia, HTN)
- course: almost completely reversible in young; elderly often left with cognitive deficits
- mortality rate 20% if untreated

Management of Alcohol Withdrawal
- monitor using the Clinical Institute Withdrawal Assessment for Alcohol (CIWA-A) scoring system
  - areas of assessment include (**SHANT AS TAV**):
    - physical (5): paroxysmal **S**weats, **H**eadache/fullness in head, **A**gitation, **N**ausea and vomiting, **T**remor
    - psychological/cognitive (2): **A**nxiety, orientation/clouding of **S**ensorium
    - perceptual (3): **T**actile disturbances, Auditory disturbances, **V**isual disturbances
    - all categories are scored from 0-7 (except: orientation/sensorium 0-4), maximum score of 67
    - mild <10, moderate 10-20, severe >20
- check for signs of hepatic failure (e.g. ascites, jaundice, and coagulopathy)

Delirium Tremens (alcohol withdrawal delirium)
- Autonomic hyperactivity (diaphoresis, tachycardia, increased respiration)
- Hand tremor
- Insomnia
- Psychomotor agitation
- Anxiety
- Nausea or vomiting
- Tonic-clonic seizures
- Visual/tactile/auditory hallucinations
- Persecutory delusions

Table 5. CIWA-A Scale Treatment Protocol for Alcohol Withdrawal

Basic protocol	Diazepam 20 mg PO q1-2 h PRN until CIWA-A <10 points
	Observe 1-2 h after last dose and re-assess on CIWA-A scale
	Thiamine 100-250 mg IM then 100 mg PO once daily for 3 d, folic acid
	Supportive care (hydration, nutrition, and electrolyte replacement)
History of withdrawal seizures	Diazepam 20 mg PO q1 h for minimum of three doses regardless of subsequent CIWA scores
If age >65 or patient has severe liver disease, severe asthma or respiratory failure	Use a short acting benzodiazepine
	Lorazepam 1-4 mg PO/SL/IM q1-2 h
If hallucinations are present	Haloperidol 2-5 mg IM/PO q1-4 h – max 5 doses/d or atypical antipsychotics (olanzapine, risperidone)
	Diazepam 20 mg x 3 doses as seizure prophylaxis (haloperidol lowers seizure threshold)
Admit to hospital if	Still in withdrawal after >80 mg of diazepam
	Delirium tremens, recurrent arrhythmias, or multiple seizures
	Medically ill or unsafe to discharge home

Wernicke-Korsakoff Syndrome
- alcohol-induced amnestic disorders due to thiamine deficiency (poor nutrition or malabsorption)
- necrotic lesions: mammillary bodies, thalamus, brainstem
- Wernicke's encephalopathy (acute and reversible): triad of oculomotor dysfunction such as nystagmus (CN VI palsy (eye pointing inwards)), gait ataxia, and confusion. If untreated, may progress to Korsakoff's syndrome
- Korsakoff's syndrome (chronic and only 20% reversible with treatment): anterograde amnesia and compensatory confabulation; cannot occur only during an acute delirium or dementia and must persist beyond usual duration of intoxication/withdrawal
- management
  - Wernicke's preventative treatment (any patient in withdrawal): thiamine 100-250 mg IM/IV x 1 dose
  - Wernicke's acute treatment: thiamine 500 mg IV BID/TID x 72 h, then reassess
  - Korsakoff's: IV treatment as for Wernicke's followed by thiamine 100 mg PO TID x 3-12 mo

Treatment of Alcohol Use Disorder
- non-pharmacological
  - see *General Approach to Treatment*, PS28
- pharmacological
  - naltrexone (Revia®): opioid antagonist, shown to be successful in reducing the "high" associated with alcohol, moderately effective in reducing cravings, frequency or intensity of alcohol binges; can be started if still consuming alcohol or abstinent but can precipitate withdrawal in those with physical opioid dependence
  - acamprosate (Campral®): NMDA glutamate receptor antagonist; useful in maintaining abstinence and decreasing cravings
  - disulfiram (Antabuse®): prevents oxidation of alcohol (blocks acetaldehyde dehydrogenase) and causes an adverse reaction to alcohol (nausea/vomiting, tachycardia, shortness of breath, headache); if patient relapses, must wait 48 h before restarting Antabuse®; prescribed only when treatment goal is abstinence; RCT evidence is generally poor or negative due to poor medication adherence; contraindicated in severe renal disease, pregnancy, psychoses, and cardiac disease
  - some evidence for the use of gabapentin, topiramate, and ondansetron as anti-craving agents, but not approved by Health Canada approved for this indication (currently under investigation)

Opioids

- types of opioids: heroin, morphine, oxycodone, Tylenol #3® (codeine), hydromorphone, fentanyl, methadone, meperidine (Demerol®)
- in addition to working on opiate receptors, opiates also act on the dopaminergic system, which mediates their addictive properties
- most commonly used are: Percocet® (oxycodone/acetaminophen), Vicodin® (hydrocodone/acetaminophen), and OxyContin® (oxycodone)
- major risks associated with the use of contaminated needles: increased risk of hepatitis B and C, bacterial endocarditis, and HIV/AIDS
- recent considerations of inadvertent overdose secondary to contamination with fentanyl in the drug supply "opioid crisis" leading to 9000 deaths in Canada between January 2016 and June 2018

Acute Intoxication
- direct effect on receptors in CNS resulting in decreased pain perception, sedation, decreased sex drive, nausea/vomiting, decreased GI motility (constipation and anorexia), pupil constriction (e.g. pinpoint pupils; exception is meperidine), and respiratory depression (can be fatal)
- medical emergency: typical syndrome includes shallow respirations, miosis, bradycardia, hypothermia, decreased level of consciousness
- management
  - ABCs
  - IV glucose
  - naloxone hydrochloride (Narcan®): 0.4 mg up to 2 mg IV for diagnosis
  - treatment: intubation and mechanical ventilation, ± naloxone drip, until patient alert without naloxone (up to >48 h with long-acting opioids)
- caution: opioids have a longer half-life than naloxone; may need to observe for toxic reaction for at least ≥24 h

Withdrawal
- symptoms: dysphoric mood, insomnia, drug-craving, myalgias, nausea or vomiting, yawning, chills, lacrimation, rhinorrhea, pupillary dilation, piloerection, sweating, diarrhea, fever; withdrawal symptoms can be severe but are not life threatening
- onset: 6-12 h (depending on half-life of opioid used); duration: 5-10 d
- complications: loss of tolerance (overdose on relapse), miscarriage, premature labour
- management: long-acting oral opioids (methadone, buprenorphine), α-adrenergic agonists (clonidine for symptomatic management of autonomic signs and symptoms of withdrawal)
- monitor withdrawal severity using Clinical Opioid Withdrawal Scale (COWS)

Opioid Antagonists
Naltrexone vs. Naloxone
Naltrexone (Revia®)
- Can be used for EtOH dependence (although not routinely used)
- Long half life (h)

Naloxone (Narcan®)
- Used for life-threatening CNS/respiratory depression in opioid overdose
- Short half life (<1 h)
- Very fast acting (min)
- High affinity for opioid receptor
- Induces opioid withdrawal symptoms

Maintenance Medication for Opiate Addiction: The Foundation of Recovery
J Addict Dis 2012;31:207-225
Maintenance treatment of opioid addiction with methadone or buprenorphine is associated with retention in treatment, reduction in illicit opiate use, decreased craving, and improved social function. Recently, studies showing extended release naltrexone injections have showed some promise.

Classic Opioid Overdose Triad (RAM)
Respiratory Depression
Altered Mental Status
Miosis

Treatment of Opioid Use Disorder

- see *General Approach to Treatment*, PS28
- long-term treatment may include maintenance treatment with methadone (opioid agonist) or buprenorphine (mixed agonist-antagonist)
- caution: methadone can cause QTc interval prolongation, screening ECG recommended
- Suboxone® formulation includes naloxone in addition to buprenorphine, in an effort to prevent injection of the drug. When naloxone is injected, it will precipitate opiate withdrawal and block the opiate effect of buprenorphine. However, it will not have this antagonist action when taken sublingually
- decreasing risk of overdose: patients with opiate use disorder should be encouraged to carry a naloxone kit and educated on ways to limit overdose risk (i.e. use with a friend, avoid mixing drugs)

Cocaine

- street names: blow, C, coke, crack, flake, freebase, rock, snow
- alkaloid extracted from leaves of the coca plant; blocks presynaptic uptake of serotonin (causing euphoria), dopamine (linked to its addictive effect), norepinephrine and epinephrine (causing vasospasm, HTN)
- sodium channel blockade: cocaine slows or blocks nerve conduction and acts as a local anesthetic by altering recovery of neuronal Na^+ channels; it has a similar effect on cardiac Na^+ channels and in overdose can manifest on ECG as prolongation of the QRS complex
- self-administered by inhalation/smoking (crack) (90% bioavailability), insufflation (i.e. intranasal; 80% bioavailability), or intravenous route
- onset and duration of action: onset within seconds if inhaled or IV, lasting 15-30 min; onset in 3-5 min if insufflated, blood levels peak at 10-20 min with effects beginning to fade after 45-60 min; cocaine has a biologic half-life of 1 h, thus repeated self-administration is common among users to maintain an effect

Intoxication

- elation, euphoria, pressured speech, restlessness, sympathetic stimulation (e.g. tachycardia, mydriasis, sweating, hypertension)
- prolonged use may result in paranoia and psychosis (including tactile hallucinations)

Overdose

- medical emergency: HTN, tachycardia, tonic-clonic seizures, dyspnea, hyperthermia, and ventricular arrhythmias
- the vasoconstrictive effects of cocaine can also result in stroke, MI, or intracranial hemorrhage
- treatment with IV diazepam to control seizures
- benzodiazepines may also be used for management of moderate agitation and anxiety, whereas severe agitation may require antipsychotics
- beta-blockers (incl. labetalol or propranolol) are not recommended because of risk from unopposed alpha-adrenergic stimulation

Withdrawal

- initial "crash" (1-48 h): increased sleep, increased appetite, dysphoria (non-life threatening)
- withdrawal (1-10 wk): dysphoric mood plus fatigue, irritability, vivid unpleasant dreams, insomnia or hypersomnia, psychomotor agitation or retardation
- complications: relapse, suicide (significant increase in suicide during withdrawal period)
- management: supportive management

Treatment of Cocaine Use Disorder

- see *General Approach to Treatment*, PS28
- no pharmacologic agents have widespread evidence or acceptance of use (some evidence for off-label use of topiramate)
- referral to psychological interventions (e.g. relapse prevention) is the mainstay of long-term treatment

Complications

- cardiovascular: arrhythmias, MI, cerebrovascular accident, ruptured AAA, chest pain (accounts for 40% of all cocaine-related ED visits)
- neurologic: seizures
- psychiatric: psychosis, delirium, suicidal ideation
- other: nasal septal deterioration, acute/chronic lung injury "crack lung," possible increased risk of connective tissue disease

Common Presentations of Drug Use

System	Findings
General	Weight loss (especially with chronic use of cocaine, heroin) Injected conjunctiva (cannabis) Pinpoint pupils (opioids) Track marks (injection drugs)
MSK	Trauma
GI	Viral hepatitis (injection drugs) Unexplained elevations in ALT (injection drugs)
Behavioural	Missed appointments Non-compliance Drug-seeking (especially benzodiazepines, opioids)
Psychological	Insomnia Fatigue Depression Flat affect (benzodiazepines, barbiturates) Paranoia (cocaine) Psychosis (cocaine, cannabis, hallucinogens)
Social	Marital discord Family violence Work/school Absenteeism and poor performance

Amphetamines

- includes prescription medications for ADHD e.g. Ritalin® and Adderall® and street drugs such as crystal meth
- intoxication characterized by euphoria, improved concentration, sympathetic and behavioural hyperactivity, and at high doses. Can mimic symptoms of psychosis or mania; can eventually cause coma
- chronic use can produce psychosis which can resemble schizophrenia with agitation, paranoia, delusions, and hallucinations
- withdrawal symptoms include dysphoria, fatigue, and restlessness
- treatment of amphetamine induced psychosis: antipsychotics for acute presentation, benzodiazepines for agitation, β-blockers for tachycardia, HTN

Cannabis

- psychoactive substance: delta-9-tetrahydrocannabinol (Δ9-THC)
- general clinical manifestations: intoxication characterized by tachycardia, conjunctival vascular engorgement, dry mouth, altered sensorium, increased appetite, and muscle relaxation
- neuropsychiatric effects:
  - altered mood, perception, and thought content: increased sense of well-being, euphoria/laughter
  - impaired cognitive and psychomotor performance: reduced reaction time, impaired attention, concentration, and short-term memory. It may also impair motor coordination required to complete complex tasks requiring divided attention. Notably, psychomotor impairments may interfere with one's ability to operate heavy machinery such as automobiles
- inhaled cannabis: onset of psychoactive effects occurs rapidly with peak effects felt 15-30 min after intake and lasting up to 4 h
  - acute exacerbation in patients with asthma may be a complication with inhalation
- ingested cannabis: following oral ingestion, psychotropic effects set in with a delay of 30-90 min, reach their maximum after 2-3 h and last for about 4-12 h depending on dose
- high doses can cause depersonalization, paranoia, anxiety and may trigger psychosis and schizophrenia if predisposed
- chronic use is associated with tolerance and an apathetic, amotivational state; may also exacerbate respiratory problems such as asthma and chronic bronchitis
- assessment: standard urine drug screens
- treatment of cannabis use disorder: see *General Approach to Treatment*, PS28
- cessation following heavy use produces a significant withdrawal syndrome: irritability, anxiety, insomnia, decreased food intake

Hallucinogens

- types of hallucinogens by primary action
  - 5-HT2A agonists: LSD, mescaline (peyote), psilocybin mushrooms, DMT (ayahuasca)
  - NMDA antagonists: PCP, ketamine
  - κ-opioid agonists: salvia divinorum, ibogaine
- 5-HT2A agonists are most commonly used; intoxication characterized by tachycardia, HTN, mydriasis, tremor, hyperpyrexia, and a variety of perceptual, mood and cognitive changes (rarely, if ever, deadly; treat vitals symptomatically)
- psychological effects of high doses: depersonalization, derealization, paranoia, and anxiety (panic with agoraphobia)
- tolerance develops rapidly (hours-days) to most hallucinogens so physical dependency is virtually impossible, although psychological dependency and harmful use patterns can still occur
- no specific withdrawal syndrome characterized but may experience "flashbacks"
- management of acute intoxication: support, reassurance, diminished stimulation; benzodiazepines (e.g. lorazepam) or high potency antipsychotics (e.g. haloperidol) seldom required (if used, use small doses), minimize use of restraints
- long term adverse effects: controversial role in triggering psychiatric disorders, particularly mood or psychosis, thought to be chiefly in individuals with genetic or other risk factors
- Hallucinogen Persisting Perception Disorder: DSM-5 diagnosis characterized by long lasting, spontaneous, intermittent recurrences of visual perceptual changes reminiscent of those experienced with hallucinogen exposure

Cannabinoid Hyperemesis Syndrome
An interesting and relatively new clinical phenomenon associated with chronic cannabis use characterized by cyclical, recurrent severe nausea, vomiting, and colicky pain. Possibly due to increased potency of available THC products. Patients often present to ED in acute distress with no evidence of specific GI pathology. Many patients will successfully self-medicate with hot baths or showers

Medical Uses of Cannabis
- Chemotherapy-induced nausea and vomiting
- Spasticity, muscle spasms (multiple sclerosis, spinal cord injury)
- Chronic pain (neuropathic pain)

Cannabis Use and Risk of Psychotic or Affective Mental Health Outcomes: A Systematic Review
The Lancet 2007;370:319-28
Purpose: To review the evidence for cannabis use and occurrence of psychotic or affective mental health outcomes.
Study Characteristics: A meta-analysis of 35 population-based longitudinal studies, or case-control studies nested within longitudinal designs.
Results: There was an increased risk of any psychotic outcome in individuals who had ever used cannabis (pooled adjusted odds ratio =1.41, 95% CI 1.20-1.65). Findings were consistent with a dose-response effect, with greater risk in people who used cannabis more frequently (2.09, 95% CI, 1.54-2.84). Findings for depression, suicidal thoughts, and anxiety outcomes were less consistent. In both cases (psychotic and affective outcomes), a substantial confounding effect was present.
Conclusions: The findings are consistent with the view that cannabis increases risk of psychotic outcomes independent of transient intoxication effects, although evidence is less strong for affective outcomes. Although cannabis use and the development of psychosis are strongly associated, it is difficult to determine causality and it is possible that the association results from confounding factors or bias. The authors did conclude that there is sufficient evidence to warn young people that using cannabis could increase their risk of developing a psychotic illness later in life.

Cannabis Use and Psychosis: A Review of Reviews
Eur Arch Psychiatry Clin Neurosci 2019;10.1007/s00406-019-01068-z
Purpose: To review the evidence on cannabis use and the development of psychosis
Methods: This study included systematic reviews and meta-analyses published after 2006. Studies on cannabis use and psychosis were included regardless of use pattern (lifetime, past year, past month, daily use, intensive use, occasional use) and type of psychosis (acute psychosis, psychotic disorders, schizophrenia).
Results: 26 systematic reviews and meta-analyses met inclusion criteria. A dose dependent relationship was identified between cannabis use and the development of psychotic illness. Cannabis users also had earlier symptom onset, increased relapse rate, more hospitalization, and more positive symptoms compared to non-users.

"Club Drugs"

Table 6. The Mechanism and Effects of Common "Club Drugs"

Drug	Mechanism	Effect	Adverse Effects
MDMA ("Ecstasy", "X", "E", "M", "Molly")	Acts on serotonergic and dopaminergic pathways, properties of a hallucinogen and stimulant	Enhanced sensorium; feelings of well-being, empathy	Diaphoresis, tachycardia, fatigue, muscle spasms (especially jaw clenching), ataxia, hyperthermia, arrhythmias, DIC, rhabdomyolysis, renal failure, seizures, death
Gamma Hydroxybutyrate (GHB, "G", "Liquid Ecstasy")	Biphasic dopamine response (inhibition then release) and releases opiate-like substance	Euphoric effects, increased aggression, impaired judgment	Diaphoresis, tachycardia, fatigue, muscle spasms (especially jaw clenching), ataxia Severe withdrawal from abrupt cessation of high doses results in tremor, seizures, psychosis
Flunitrazepam (Rohypnol®, "Roofies", "Rope", "The Forget Pill")	Potent benzodiazepine, rapid oral absorption	Sedation, psychomotor impairment, amnestic effects, decreased sexual inhibition	CNS depression with EtOH
Ketamine ("Special K", "Kit-Kat")	NMDA receptor antagonist, rapid-acting general anesthetic used in paediatrics and by veterinarians	"Dissociative" state, profound amnesia/analgesia, hallucinations and sympathomimetic effects	Psychological distress, accidents due to intensity of experience and lack of bodily control In overdose: decreased LOC, respiratory depression, catatonia
Methamphetamine ("speed", "meth", "chalk", "ice", "crystal")	Amphetamine stimulant, induces norepinephrine, dopamine, and serotonin release	Rush begins in min, effects last 6-8 h, increased activity, decreased appetite, general sense of well-being, tolerance occurs quickly, users often binge and crash	Short-term use: high agitation, rage, violent behaviour, occasionally hyperthermia and convulsions Long-term use: addiction, anxiety, confusion, insomnia, paranoia, auditory and tactile hallucinations (especially formication), delusions, mood disturbance, suicidal and homicidal thoughts, stroke May be contaminated with lead, and IV users may present with acute lead poisoning
Phencyclidine ("PCP", "angel dust")	Not understood, used by veterinarians to immobilize large animals	Amnestic, euphoric, hallucinatory state	Horizontal/vertical nystagmus, myoclonus, ataxia, autonomic instability (treat with diazepam IV), prolonged agitated psychosis (treat with haloperidol) High-risk for suicide; violence towards others High dose can cause coma

Date Rape Drugs
- GHB
- Flunitrazepam (Rohypnol®)
- Ketamine (sometimes used as it is tasteless and odourless)

Formication
Tactile hallucination that insects or snakes are crawling over or under the skin (especially associated with crystal meth use but also observed among some cocaine and PCP users)

Emerging Medical Uses of Hallucinogens
Many hallucinogens are currently under investigation for therapeutic benefit; LSD & psilocybin for end of life anxiety, MDMA for PTSD, ketamine for rapid treatment of depression, ibogaine derivatives for addiction

Malingering: intentional production of false or grossly exaggerated physical or psychological symptoms, motivated by secondary gain/external reward (e.g. avoiding work, obtaining financial compensation, or obtaining drugs)

Factitious Disorder: intentional production or feigning of physical or psychological signs or symptoms. Unlike malingering, patients are not motivated by secondary gain but rather may seek sympathy, nurturance, and attention

Somatic Symptom and Related Disorders

General Characteristics

- physical signs and symptoms lacking objective medical support in the presence of psychological factors that are judged to be important in the initiation, exacerbation, or maintenance of the disturbance (suffering is out of keeping with what would be normally expected)
- cause significant distress or impairment in functioning
- symptoms are produced unconsciously and are not the result of malingering or factitious disorder, which are disorders of voluntary presentation of symptoms (or intentionally inducing, e.g. injecting feces) for secondary gain
- primary gain: somatic symptom represents a symbolic resolution of an unconscious psychological conflict; serves to reduce anxiety and conflict with no external incentive
- secondary gain: the sick role; external benefits obtained, or unpleasant duties avoided (e.g. work)
- theories for root cause: may represent a masked presentation of a psychiatric issue, amplified perception; social/cultural norms that devalue psychological suffering; lack of ability/language to express distress in a non-somatic way

Management of Somatic Symptom and Related Disorders

- brief, regular scheduled visits with GP to facilitate therapeutic relationship and help patient feel supported (e.g. q4-6 wk)
- good, clear communication among all involved care providers
- limit number of physicians involved in care, minimize medical investigations, coordinate necessary investigations
- emphasis on mechanism of the symptoms and not on the cause while focusing on what the patient can change and control; the psychosocial coping skills, not their physical symptoms (functional recovery > explanation of symptoms)

- focus on functional improvement (physiotherapy, occupational therapy), provide psychoeducation to validate suffering in the face of medically unexplained symptoms
- psychotherapy: CBT, psychodynamic therapy, mindfulness interventions, biofeedback
- minimize psychotropic drugs: anxiolytics for short-term use only (associated with worse outcomes), antidepressants for comorbid depression and anxiety

Somatic Symptom Disorder

DSM-5 DIAGNOSTIC CRITERIA FOR SOMATIC SYMPTOM DISORDER

Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. one or more somatic symptoms that are distressing or result in significant disruption of daily life
B. excessive thoughts, feelings, or behaviours related to the somatic symptoms or associated health concerns as manifested by at least one of the following:
    1. disproportionate and persistent thoughts about the seriousness of one's symptoms
    2. persistently high level of anxiety about health or symptoms
    3. excessive time and energy devoted to these symptoms or health concerns
C. although any one somatic symptom may not be continuously present, the state of being symptomatic is persistent (typically >6 mo)

- **somatic symptom disorder with predominant pain** (previously pain disorder) for those whose somatic symptom is primarily pain
- patients have physical symptoms and believe these symptoms represent the manifestation of a serious illness
- persistent belief despite negative medical investigations and may develop different symptoms over time
- lifetime prevalence may be around 5-7% in the general adult population
- females tend to report more somatic symptoms than males do; cultural factors may influence sex ratio
- other risk factors include: history of sexual abuse, lower education and socioeconomic status, and concurrent psychiatric/chronic physical illnesses
- complications: anxiety and depression commonly comorbid (up to 80%), unnecessary medications, or surgery
- often a misdiagnosis for an insidious illness, so rule out all organic illnesses (e.g. multiple sclerosis)
- DDx: GAD, depressive disorder, delusional disorder, body dysmorphic disorder, obsessive compulsive disorder, other medical condition

Illness Anxiety Disorder

- preoccupation with fear of having, or the idea that one has a serious disease to the point of causing significant impairment
- convictions persist despite negative investigations and medical reassurance; however, able to acknowledge the possibility that feared disease is not present, unlike a delusion, which is fixed and firm
- somatic symptoms are mild or not present (not acute)
- there is a high level of anxiety about health and the individual is easily alarmed about personal health status
- person engages in maladaptive behaviour such as excessive physical checking or total healthcare avoidance
- duration is ≥6 mo; onset in 3rd-4th decade of life
- epidemiology: 3-5% of patients seen by primary care physicians; increased risk of substance use problems
- possible role for SSRIs as treatment due to generally high level of anxiety
- specifiers: care-seeking type or care-avoidant type

Conversion Disorder (Functional Neurological Symptom Disorder)

- one or more symptoms or deficits affecting voluntary motor or sensory function that mimic a neurological or GMC (e.g. impaired coordination, local paralysis, double vision, seizures, or convulsions)
- does not need to be preceded by a psychological event as per previous DSM criteria, however this is still worth exploring as many patients will present after such an event or related to a medical diagnosis in a first-degree relative
- incidence of 2-5 in 100000 in general population; up to 20-25% of neurology inpatients and 5% of psychiatry inpatients
- more common in rural populations and in individuals with little medical knowledge
- spontaneous remission in 95% of acute cases, 50% of chronic cases (>6 mo)
- incompatible findings detected from specific neurological testing can help differentiate between functional and neurological origin (e.g. Hoover's sign and dermatome testing)
- for more details about Conversion Disorder, please consult the DSM-5

Screening questions for somatic disorders

1. When did the symptoms start?
2. Have you been frustrated with getting no answers?
3. What has been your experience with other physicians?
4. What Is your understanding of your symptoms?
5. How have the symptoms affected your life?

Table 7. Differential of Somatic Symptom and Related Disorders

	Somatic Symptom Disorder	Illness Anxiety Disorder	Conversion Disorder	Factitious Disorder	Malingering
Somatic Symptoms	Present	Mild or absent	Neurologic, voluntary motor or sensory	Psychological or physical	Psychological or physical
Symptoms Produced	Unconsciously	Unconsciously	Unconsciously	Consciously	Consciously
Physical Findings	Absent	Absent	Incompatible	Possible, attempts to falsify	Possible, attempts to falsify

La belle indifference: an inappropriately cavalier patient attitude in the face of serious symptoms; classically associated with conversion disorder but is not diagnostic

Hoover's sign: involuntary extension of the "normal" leg occurs when flexing the contralateral leg against resistance

Dissociative Disorders

General Characteristics

- severe dissociation resulting in breakdown of integrated functions of consciousness and perception of self
- severe stress or traumas are predisposing factors for dissociative disorders (e.g. victims of significant or chronic trauma, child abuse)
- result in significant distress or impairment in social/occupational functioning
- psychotherapy (psychodynamic, CBT) are the mainstays of treatment; lack of evidence for use of medications
- DDx: PTSD, acute stress disorder, borderline personality disorder, somatic symptom disorder, substance use disorder, GMC (various neurologic disorders including complex/partial seizures, migraine, Cotard syndrome)

Dissociative Identity Disorder

- disruption of identity characterized by ≥2 distinct personality states or an experience of possession
- can manifest as sudden alterations in sense of self and agency (ego-dystonic emotions, behaviours, speech)
- features recurrent episodes of amnesia (declarative or procedural) as well as episodes of depersonalization and derealization
- rare (<1%); can manifest at any age, although childhood physical/sexual abuse or neglect is a major risk factor
- caution: high-risk of attempting suicide and/or self-harm
- DDx includes borderline personality disorder and PTSD

Dissociative Amnesia

- inability to recall important autobiographical information, usually of a traumatic or stressful nature that is inconsistent with normal forgetting and not attributable to a psychiatric disorder, medical illness, or effects of a substance
- localized/selective amnesia: failure to recall all/some events during a prescribed period of time (however procedural memory is preserved)
- can experience periods of flashbacks or nightmares related to associated trauma, increased risk of suicide as amnesia resolves
- generalized amnesia (more rare): complete loss of memory for one's life history, ± procedural knowledge, ± semantic knowledge; usually sudden onset; often presents with perplexity, disorientation, and aimless wandering

Dissociative Fugue
Sudden unexpected travel away from home that is accompanied by amnesia for identity or other autobiographical details

Depersonalization/Derealization Disorder

- persistent or recurrent episodes of one or both of:
  - depersonalization: experiences of detachment from oneself, feelings of unreality, or being an outside observer to one's thoughts, feelings, speech, and actions (can feature distortions in perception including time, as well as emotional and physical numbing)
  - derealization: experiences of unreality or detachment with respect to the surroundings (i.e. feeling as if in a dream, or that the world is not real; external visual world is foggy or distorted)
- transient (s-h) experiences of this nature are quite common in the general population
- episodes can range from h-yr, patients are often quite distressed and verbalize concerns of "going crazy"

During depersonalization (detachment from one's self) or derealization (detachment from one's surroundings), patients usually have intact reality testing, which adds to their alarming nature

Sleep Disorders

- for more information regarding normal sleep cycles and the illnesses described, see Neurology, *Sleep Disorders*, N48

Overview

- adequate sleep is essential to normal functioning; deprivation can lead to cognitive impairment and increased mortality
- circadian rhythms help regulate mood and cognitive performance
- neurotransmitters commonly implicated in psychiatric illnesses also regulate sleep
  - increased ACh activity and decreased activity of monoamine neurotransmitters is associated with greater REM sleep
  - decreased adrenergic and cholinergic activity are associated with NREM sleep
- depression is associated with decreased Δ (deep, slow-wave) sleep, decreased REM latency, and increased REM density
- criteria for sleep disorders:
  - must cause significant distress or impairment in normal functioning
  - not due to a General Medical Condition (GMC) or medications/drugs (unless specified)

Management

- sleep hygiene is a simple, effective, but often underutilized method for addressing sleep disturbances; recommendations include:
  - waking up and going to bed at same time every day, including on weekends
  - avoiding long periods of wakefulness in bed
  - not using bed for non-sleep activities (reading, TV, work)
  - avoiding screens, especially smartphones and iPads in the hour before bed
  - avoiding napping
  - discontinuing or reducing consumption of alcohol, caffeine, drugs
  - exercising at least 3-4x/wk (but not in the evening, if this interferes with sleep)
- cognitive behavioural therapy for insomnia (CBTi) is considered first-line treatment for chronic insomnia
- pharmacological treatments are illness-specific
  - avoid benzodiazepenes: increased risk of abuse/dependence, rebound anxiety/insomnia, cognitive impairment, daytime somnolence, and disturbed sleep architecture (suppresses deep and REM sleep)
  - non-benzodiazepines (e.g. zopiclone/eszopiclone/zolpidem, lemborexant, low dose doxepin) are preferred and effective for short-term treatment; they should be re-evaluated regularly as long-term use is associated with dependency
  - "z-drugs": common side-effect is bitter metallic taste, which is improved by something acidic such as orange juice; high doses increase risk of cognitive impairment and falls (particularly among the elderly)
  - lemborexant (orexin receptor antagonist) reduces wake pressure/drive, as opposed to increasing sleep pressure/drive with other sedating agents; avoid use in patients with narcolepsy or cataplexy
  - trazodone, mirtazapine, and quetiapine can be prescribed off-label if there are comorbid psychiatric symptoms
  - low-dose amitriptyline can be prescribed for patients with comorbid pain
  - screen for complex sleep behaviours before and after prescribing a medication for insomnia
  - consider whether sleep issue is part of another psychiatric or medical illness and treat those conditions

Table 8. Major DSM-5 Sleep-Wake Disorders

Note: For more information regarding specific disorders, see Neurology, *Sleep Disorders*, N48; Family Medicine, *Sleep Disorders*, FM48; and Respirology, *Sleep Apnea*, R29

Category	Disorder	Description	Management
Dyssomnias (insufficient, excessive, or altered timing of sleep)	**Insomnia disorder**	Difficulty initiating/maintaining sleep or early-morning awakening with inability to return to sleep; can be acute or chronic (≥3 mo)	Sleep hygiene measures CBT for insomnia Non-benzodiazepines are first-line ("z-drugs", lemborexant, low dose doxepin)
	Hypersomnolence disorder	Excessive daytime sleepiness despite sleeping at least 7 h; difficulty being fully awake after awakening at least 3 times per wk for at least 3 mo	Modafinil or stimulant drugs Scheduled napping
	Narcolepsy	Classic tetrad consists of recurrent attacks of irrepressible need to sleep (sleep attacks), REM-related sleep phenomena, hypnagogic or hypnopompic hallucinations, and cataplexy (sudden loss of tone evoked by strong emotion without LOC)	Sleep hygiene Amphetamines (methamphetamine) Non-amphetamines (Modafinil, sodium oxybate)
	Circadian rhythm sleep-wake disorders	Insomnia or excessive sleepiness due to misalignment or alteration in endogenous circadian rhythm	Melatonin Bright light phototherapy Modafinil if severe
	Restless legs syndrome	Uncomfortable, frequent urge to move legs at night; relief with movement and aggravation with inactivity	Dopamine agonists and benzodiazepines are first-line Replace iron if low ferritin Modify medications that may be exacerbating symptoms
	Substance/medication-induced sleep disorder	Disturbance in sleep (insomnia or daytime sleepiness) caused by substance/medication intoxication or withdrawal	
Breathing-Related Sleep Disorders	**Obstructive sleep apnea hypopnea**	Breathing issues due to repetitive collapse of the upper airway during sleep - resulting in nonrestorative sleep and excessive daytime sleepiness; snoring, disrupted sleep, and morning headaches are common signs	Continuous positive airway pressure (CPAP) Weight loss/exercise Surgery
	Central sleep apnea	Breathing issues due to aberrant brain signaling More common among chronic opioid users	CPAP/bilevel positive airway pressure (BiPAP) Supplemental oxygen
	Sleep-related hypoventilation	Breathing issues due to decreased responsiveness to carbon dioxide levels (decreased respiration)	CPAP/BiPAP Medications that support breathing
Parasomnias (unusual sleep-related behaviours)	**Non-rapid eye movement sleep arousal disorders**	Incomplete awakening from sleep, complex motor behaviour without conscious awareness; amnesia regarding episodes; includes symptoms of:	
		Sleepwalking: rising from bed and walking about, blank face, unresponsive, awakened with difficulty	Most cases do not require treatment aside from addressing precipitating factors and education regarding sleep hygiene Severe cases may respond to low-dose clonazepam
		Sleep terrors: recurrent episodes of abrupt terror arousals from sleep, usually beginning with a panicky scream, intense fear, and autonomic arousal; relative unresponsiveness to comfort during episodes	Often self-limited and benign
		Specifiers: sleep-related sexual behaviour (sexsomnia) and sleep-related eating	
	Nightmare disorder	Repeated extended, extremely dysphoric, often very vivid, well-remembered dreams that usually involve significant threats; rapid orientation and alertness on awakening with autonomic arousal	Reassurance Desensitization/imagery rehearsal therapy Prazosin can be helpful for those with PTSD
	Rapid eye movement sleep behaviour disorder	Arousal during sleep, associated with vocalization and/or complex motor behaviours; can cause violent injuries; rapid orientation and alertness on awakening	Melatonin Clonazepam Discontinuation of causative medications such as TCAs, SSRIs and SNRIs

Sexuality and Gender

Gender Dysphoria

Definition

- discomfort or distress caused by a discrepancy between sex assigned at birth and a person's gender identity
- gender identity refers to a person's intrinsic sense of self as male, female, both, neither, or anywhere along the spectrum
- for more details about Gender Dysphoria, please consult the DSM-5

Clinical Features

- strong and persistent cross-gender identification
- desire to be rid of primary/secondary sex characteristics and to gain the primary/secondary sex characteristics of their identified gender
- repeated stated desire or insistence that one is of the opposite sex

- preference for cross-dressing, cross-gender roles in make-believe play
- intense desire to participate in the stereotypical games and pastimes of the opposite sex
- strong preference for playmates of the opposite sex
- significant distress or impairment in functioning and persistent discomfort with his or her sex or gender role

Management
- supportive psychotherapy or other mental health counselling
- hormone therapy with feminizing (e.g. estrogen and anti-androgen) or masculinizing (e.g. testosterone) agents
- gender affirming surgery

Paraphilic Disorders

Definition
- intense and persistent sexual arousal, over a period of at least 6 mo, that is elicited by something other than genital stimulation or preparatory fondling with phenotypically normal, physically mature, consenting human partners
- paraphilic disorder: when paraphilia causes distress or functional impairment to the individual, or a paraphilia whose realization entails personal harm or risk of harming others

Clinical Features
- begins in childhood or early adolescence; increasing complexity and stability with age
- tends to be chronic but decreases in intensity with advancing age; may increase with stress
- rarely self-referred; come to medical attention through interpersonal or legal conflict
- person usually has more than one paraphilia; more common in men (only 5% of patients with paraphilia are women)
- subtypes:
  - voyeuristic - sexual arousal when spying intentionally on unsuspecting individuals
  - exhibitionistic - sexual arousal from the act or fantasy of exposing one's genitals to non-consenting individuals
  - frotteuristic - sexual arousal from touching or rubbing one's genitals up against non-consenting individuals
  - sexual masochism - sexual arousal from being humiliated, beaten, bound, or otherwise made to suffer
  - sexual sadism - sexual arousal from the psychological or physical suffering of a victim including humiliation
  - pedophilic - sexual attraction to prepubescent children - may be exclusive (only children) or nonexclusive (children and adults)
  - fetishistic - recurrent, intense sexual arousal from an inanimate object or specific focus on a non-genital body part(s)
  - transvestic - sexual arousal from act or fantasies of cross-dressing
  - other specified paraphilic disorder or unspecified paraphilic disorder

Management
- anti-androgen drugs (e.g. medroxyprogesterone or leuprolide)
- SSRIs (e.g. high-dose fluoxetine)
- behaviour modification
- psychotherapy

Sexual Addiction

- definition: engaging in persistent and escalating patterns of sexual behaviour, despite increasing negative consequences to self and others
- clinical features: may be characterized by compulsive searching for multiple sexual partners, persistent thoughts of or craving for sex to the detriment of other activities, compulsive masturbation, extensive use of pornography, compulsive sexuality in a relationship, and feelings of remorse or guilt after sex
- management: CBT, 12-step programs, SSRIs to reduce libido

Sexual Dysfunction

- important to identify treatable causes (e.g. atrophic vaginitis, diabetes, antidepressant medications)
- see Gynaecology, GY34 and Urology, U33

Eating Disorders

Definition
- eating disorders are characterized by a persistent disturbance of eating that impairs psychosocial functioning or health
- disorders include: anorexia nervosa, avoidant/restrictive food intake disorder, binge eating disorder, bulimia nervosa, pica, and rumination disorder

Epidemiology
- anorexia nervosa (AN): 1% of adolescent and young adult females; 0.3% males; onset in mid-teens (14-18 yr)
- bulimia nervosa (BN): 2-4% of adolescent and young adult females; 0.5% males; onset in late teens or early adulthood
- F:M=10:1; mortality of AN 5-10%
- common comorbidities: depression (50-75%), substance misuse (35% in BN, 15% in AN), OCD (25% in AN)

Etiology
- multifactorial: psychological, sociological, and biological associations
- individual: perfectionism, lack of control in other life areas, history of sexual abuse
- personality: anxiety, perfectionism, obsessionality, negative emotionality, cognitive inflexibility
- family & sociocultural: invalidating family structure, prevalent in industrialized societies, idealization of thinness in the media, athletic demands
- puberty
- genetic factors
  - AN: 6% prevalence in siblings, with one study of twin pairs finding concordance in 9 of 12 monozygotic pairs vs. concordance in 1 of 14 dizygotic pairs (10x greater risk among first-degree relatives)
  - BN: higher familial incidence of affective disorders than the general population

Risk Factors
- physical factors: obesity, chronic medical illness (e.g. DM)
- psychological factors: individuals who by career choice are expected to be thin, family history (mood disorders, eating disorders, substance use disorder), history of sexual abuse (especially for BN), competitive athletes, concurrent associated mental illness (depression, OCD, anxiety disorder (especially panic and agoraphobia), substance use disorder (specifically for BN))

Complications
- growth delay, osteoporosis (40%), osteopenia (50%), cardiovascular complications (bradycardia, QTc prolongation, starvation edema), gastrointestinal complications (irritable bowel syndrome, constipation, gastric dilation), electrolyte disturbances (hypokalemia, hypomagnesemia, hypophosphatemia), refeeding syndrome, and endocrine abnormalities (increased GH, reduced LH, FSH, and T3)

Eating Disorder Screening
Method to identify patients with eating disorders. A "Yes" to two or more questions is associated with a sensitivity and specificity of 78 and 88%, respectively

SCOFF
- Do you make yourself **S**ick because you feel uncomfortably full?
- Do you worry you have lost **C**ontrol over how much you eat?
- Have you recently lost more than **O**ne stone (14 pounds or 6.35 kg) in a 3 mo period?
- Do you believe yourself to be **F**at when others say you are too thin?
- Would you say that **F**ood dominates your life?

Anorexia Nervosa

DSM-5 DIAGNOSTIC CRITERIA FOR ANOREXIA NERVOSA
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. restriction of energy intake relative to requirements, leading to a significantly low body weight in the context of age, sex, developmental trajectory, and physical health. Significantly low weight is defined as a weight that is less than minimally normal or, for children and adolescents, less than that minimally expected
B. intense fear of gaining weight or of becoming fat, or persistent behaviour that interferes with weight gain, even though at a significantly low weight
C. disturbance in the way in which one's body weight or shape is experienced, undue influence of body weight or shape on self-evaluation, or persistent lack of recognition of the seriousness of the current low body weight

- **specifiers**: partial remission, full remission, severity based on BMI (mild = BMI >17 kg/m^2, moderate = BMI 16-16.99 kg/m^2, severe = BMI 15-15.99 kg/m^2, extreme = BMI <15 kg/m^2), type (restricting = during last 3 mo no episodes of binge-eating or purging vs. binge-eating/purging type = in last 3 mo have participated in recurrent episodes of binge-eating/purging)

Athletic Triad
Disordered eating
Amenorrhea
Osteoporosis

Some patients with insulin-dependent DM may stop their insulin in order to lose weight

Management
- standard work-up: vitals (weight and orthostatic BP and HR), bloodwork (CBC, electrolytes, creatinine, liver enzymes, B_{12}, TSH), ECG
- psychotherapy: individual, group, family; address food and body perception, coping mechanisms, health effects
- CBT: sets clear weight goals and expectations, makes use of recording sheets, targets maintaining factors such as negative body image
- family-based treatment is primarily used in the paediatric system, main focus is on weight restoration and return to physical health
- medications of little value; however, SSRIs may be helpful in treating concurrent mood and anxiety disorders
- outpatient and inpatient programs are available (nutritional rehabilitation)
- inpatient psychiatric hospitalization for treatment of eating disorders is rarely on an acute basis (unless there is a concurrent psychiatric reason for emergent admission (e.g suicide risk)). Such patients often require a specialized ED program.
- criteria to admit to medical ward for hospitalization: <65% of standard body weight (<85% of standard body weight for adolescents), hypovolemia requiring intravenous fluid, heart rate <40 bpm, abnormal serum chemistry (e.g. low K^+, low Mg^{2+}, Low PO_4^{3-}, high creatinine), or if actively suicidal
- agree on target body weight on admission and reassure this weight will not be surpassed
- monitor for complications of AN (see Table 9, PS42)
- monitor for refeeding syndrome
  - potentially life-threatening metabolic response to refeeding in severely malnourished patients resulting in severe shifts in fluid and electrolyte levels
  - complications include hypophosphatemia, congestive heart failure, cardiac arrhythmias, delirium, and death
  - prevention: slow refeeding, gradual increase in nutrition, supplemental phosphorus, and close monitoring of electrolytes and cardiac status

Prognosis
- adolescent onset has much better prognosis than adult onset
- only about 50% make a full recovery
- with treatment, 70% resume a weight of at least 85% of expected levels and about 50% resume normal menstrual function
- eating peculiarities and associated psychiatric symptoms are common and persistent
- high rates of mortality (7%) secondary to severe and chronic starvation, metabolic or cardiac catastrophes, with a significant proportion dying by suicide

Bulimia Nervosa

DSM-5 DIAGNOSTIC CRITERIA FOR BULIMIA NERVOSA
Reprinted with permission from the Diagnostic and Statistical Manual of Mental Disorders, 5th ed. 2013. American Psychiatric Association

A. recurrent episodes of binge-eating; an episode of binge-eating is characterized by both of the following:
   - eating, in a discrete period of time, an amount of food that is definitely larger than what most individuals would eat during a similar period of time and under similar circumstances
   - a sense of lack of control over eating during the episode

B. recurrent inappropriate compensatory behaviour in order to prevent weight gain, such as self-induced vomiting, misuse of laxatives, diuretics, enemas, or other medications, fasting, or excessive exercise

C. the binge-eating and inappropriate compensatory behaviours both occur, on average, at least once a week for 3 mo

D. self-evaluation is unduly influenced by body shape and weight

E. the disturbance does not occur exclusively during episodes of AN

- **specifiers**: partial remission, full remission, severity (mild = 1-3 inappropriate compensatory behaviours/wk, moderate = 4-7 inappropriate compensatory behaviours/wk, severe = 8-13 inappropriate compensatory behaviours/wk, extreme = 14+ inappropriate compensatory behaviours/wk)

Associated Features
- fatigue and muscle weakness due to repetitive vomiting and fluid/electrolyte imbalance
- tooth decay, perioral irritation, mouth ulcers
- swollen appearance around angle of jaw and puffiness of eye sockets due to fluid retention, edema
- reddened knuckles, Russell's sign (knuckle callus from self-induced vomiting)
- trouble concentrating, fatigue, headache, abdominal pain/reflux
- weight fluctuation over time

Management
- medical admission for significant electrolyte abnormalities
- biological: treatment of starvation effects, SSRIs (60 mg fluoxetine has the most evidence) as adjunct
- psychological: develop trusting relationship with therapist to explore personal etiology and triggers, CBT, family therapy, recognition of health risks
- social: challenge destructive societal views of women, use of hospital environment to provide external patterning for normative eating behaviour

Prognosis
- relapsing/remitting disease
- good prognostic factors: onset before age 15, achieving a healthy weight within 2 yr of treatment
- poor prognostic factors: later age of onset, previous hospitalizations, individual and familial disturbance
- 60% good treatment outcome, 30% intermediate outcome, 10% poor outcome (mortality rate of approximately 2% per decade)

Binge-Eating Disorder

Definition
- recurrent episodes of binge-eating (as defined by criteria A of BN) that are associated with eating much more rapidly than normal, eating until feeling uncomfortably full, eating large amounts when not physically hungry, eating alone because embarrassed by how much one is eating, and/or feeling disgusted with oneself/depressed/very guilty afterwards at least once/wk x 3 mo
- not associated with any compensatory behaviours
- dieting usually follows binge-eating (vs. BN where dysfunctional dieting typically precedes binge-eating)
- for more details about Binge-Eating Disorder, please consult the DSM-5

Epidemiology
- F:M=2:1
- begins in adolescence or young adulthood

Treatment
- CBT

Avoidant/Restrictive Food Intake Disorder

Definition
- eating/feeding disturbance (i.e. apparent lack of interest in eating or food) to the extent of persistent failure to meet appropriate nutritional and/or energy needs, resulting in significant weight loss/growth failure and nutritional deficiencies; patients experience disturbances in psychosocial functioning and may become dependent on enteral feeding/oral nutritional supplementation
  - does not occur during an episode of AN or BN and not better explained by lack of available food or culturally sanctioned practice
  - no evidence of distress in the way in which one's body weight or shape is experienced

Risk Factors
- temperament (e.g. anxiety disorders), environment (e.g. familial anxiety), genetic (e.g. history of GI conditions)
- begins in infancy and can persist into adulthood

Treatment
- psychoeducation
- behaviour modification
- psychotherapy

Points for Differentiating Between Eating Disorders
- AN of binge-eating/purging type (significantly low body weight) takes priority over a BN diagnosis (body weight not in criteria)
- BN requires compensatory behaviours
- Binge-eating disorder does not involve compensatory behaviours
- Avoidant/restrictive food intake disorder does not involve disturbances in body image

Table 9. Physiologic Complications of Eating Disorders

System	Starvation/Restriction	Binge-Purge
General	Low BP	Russell's sign (knuckle callus)
	Low HR	Parotid gland enlargement
	Significant orthostatic changes ± syncopal episodes Low body temperature	Perioral skin irritation and mouth ulcers
	Vitamin deficiencies	Periocular and palatal petechiae
	Emaciation	Loss of dental enamel and caries
	Sleep disturbances	Aspiration pneumonia
	Fatigue/weakness	Metabolic alkalosis secondary to hypokalemia and loss of acid
		Fatigue
Endocrine	Primary or secondary amenorrhea, cold intolerance, decreased T3/T4	
Neurologic	Seizure (decreased Ca^{2+}, Mg^{2+}, PO_4^{3-})	
Cutaneous	Dry skin, lanugo hair, hair loss or thinning, brittle nails, yellow skin from high carotene	
GI	Constipation, GERD, delayed gastric emptying, abdominal pain	Acute gastric dilation/rupture, pancreatitis, GERD, hematemesis secondary to Mallory-Weiss tear
CVS	Arrhythmias, CHF	Arrhythmias, cardiomyopathy (from use of ipecac), sudden cardiac death (decreased K^+)
MSK	Osteoporosis secondary to hypogonadism	Muscle wasting
Renal	Pre-renal failure (hypovolemia), renal calculi	Renal failure (electrolyte disturbances)
Extremities	Pedal/periorbital edema (decreased albumin)	Pedal/periorbital edema (decreased albumin)
Lab Values	Starvation: decreased RBCs, decreased WBCs, decreased LH, decreased FSH, decreased estrogen, decreased testosterone, increased GH, increased cholesterol	Vomiting: decreased Na^+, decreased K^+, decreased Cl^-, decreased H^+, increased amylase; hypokalemia with metabolic alkalosis
	Dehydration: increased BUN	Laxatives: decreased Na^+, decreased K^+, decreased Cl^-, increased H^+; metabolic acidosis

Important electrolytes in eating disorders: KPMg (potassium, phosphate, magnesium)

Personality Disorders

- in the literature, personality and its disorders can be understood using a trait-based dimensional approach (i.e. 5 major traits such as extraversion, agreeableness, conscientiousness, neuroticism, and openness to experiences rated on a continuum of dysfunctional effects) rather than discrete categories; however, the discrete categories still remain in the current DSM and will be referenced here

A flag for personality disorders in clinical setting is the reaction that a patient is eliciting in you

General Information

- an enduring pattern of inner experience and behaviour that deviates markedly from the expectations of the individual's culture; manifested in two or more of: cognition, affect, interpersonal functioning, impulse control
- inflexible and pervasive across a range of situations
- pattern is stable and well-established by adolescence or early adulthood (i.e. not a sudden onset)
- associated with many comorbidities such as depression, suicide, violence, brief psychotic episodes, substance use, and treatment resistance
- relationship building and establishing boundaries are important; focus should be placed on validating, finding things to be truly empathetic about, and speaking to the patient's strengths
- mainstay of treatment is psychotherapy (e.g. CBT, interpersonal psychotherapy, psychodynamic psychotherapy, DBT); add pharmacotherapy to treat associated psychiatric disorders (e.g. depression, anxiety, substance misuse)

Personality disorders with familial associations: schizotypal, antisocial, and borderline

Classification

- personality disorders are divided into three clusters (A, B, and C), with shared features among disorders within each

Table 10. Description and Diagnosis of Personality Disorders

Cluster A: "Mad" Personality Disorders
- Patients seem odd, eccentric, withdrawn
- Familial association with psychotic disorders
- Common defense mechanisms: intellectualization, projection, magical thinking

Paranoid Personality Disorder (1-4% of general population)
Pervasive distrust and suspiciousness of others, interpret motives as malevolent
Blame problems on others and seem angry and hostile
Diagnosis requires 4+ of: **SUSPECT**
1. **S**uspicious that others are exploiting or deceiving them (without sufficient basis)
2. **U**nforgiving (bears grudges)
3. **S**pousal infidelity suspected without justification
4. **P**erceive attacks on character, counterattacks quickly
5. **E**nemies or friends? Preoccupied with acquaintance trustworthiness
6. **C**onfiding in others is feared
7. **T**hreats interpreted in benign remarks
(Note: Must rule out psychotic disorder where no true delusions or hallucinations present)

Schizotypal Personality Disorder (4-5% of general population)
Pervasive pattern of social and interpersonal deficits, cognitive/perceptual distortions, eccentric behaviours, and peculiar thought patterns
Diagnosis requires 5+ of: **ME PECULIAR**
1. **M**agical thinking
2. **E**xperiences unusual perceptions (including body illusions)
3. **P**aranoid ideation
4. **E**ccentric behaviour or appearance
5. **C**onstricted or inappropriate affect
6. **U**nusual thinking/speech (e.g. vague, stereotyped)
7. **L**acks close friends
8. **I**deas of reference
9. **A**nxiety in social situations that does not diminish with familiarity (related to fears)
(Note: **R**ule out psychotic/pervasive developmental disorders - this is not part of the criteria; the more fixed and systematic a belief is, the more likely it is of delusional intensity)

Schizoid Personality Disorder (3-5% of general population)
Neither desires nor enjoys close relationships including being a part of a family; prefers to be alone. Lifelong pattern of social withdrawal. Seen as eccentric and reclusive with restricted affect in a variety of contexts
Diagnosis requires 4+ of: **DISTANT**
1. **D**etached/flat affect, emotionally cold
2. **I**ndifferent to praise or criticism
3. **S**exual experiences of little interest
4. **T**asks done solitarily
5. **A**bsence of close friends (other than first-degree relatives)
6. **N**either desires nor enjoys close relationships (including family)
7. **T**akes pleasure in few (if any) activities

Cluster B: "Bad" Personality Disorders
- Patients seem dramatic, emotional, inconsistent, and impulsive
- Sensitive to perceived criticism, abandonment, or lack of attention; difficulty with interpersonal relationships due to self-serving, hostile, or erratic behaviour
- Familial association with mood disorders
- Common defense mechanisms: denial, acting out, regression (histrionic PD), splitting (borderline PD), projective identification, idealization/devaluation

Borderline Personality Disorder (1-2% of general population)
A pervasive pattern of instability of interpersonal relationships, self-image, and affects; marked impulsivity
Strong correlation with a history of childhood sexual abuse. Characterized by interpersonal, cognitive, behavioural, and affective deficits. Often exposed to an emotionally invalidating environment. The more dramatic behaviour tends to diminish as patients age. DBT is the principal treatment (see *Psychotherapy*, PS50)
10% suicide rate
Diagnosis requires 5+ of: **IMPULSIVE**
1. **I**mpulsive (minimum of 2 self-damaging ways, e.g. sex/drugs/spending)
2. **M**ood/affect instability
3. **P**aranoia or dissociation under stress
4. **U**nstable self-image
5. **L**abile intense relationships (extremes of idealization and devaluation)
6. **S**uicidal gestures/self-harm
7. **I**nappropriate anger
8. **V**oiding abandonment (real or imagined, frantic efforts to)
9. **E**mptiness (feelings of)
(Note: More frequently diagnosed in females but research suggests equal gender distribution)

Narcissistic Personality Disorder (around 6% of general population)
Sense of superiority, needs constant admiration, lacks empathy, but with fragile sense of self. Consider themselves "special" and will exploit others for personal gain. Beginning by early adulthood and present in a variety of contexts
Diagnosis requires 5+ of: **GRANDIOSE**
1. **G**randiose sense of self-importance (e.g. exaggerates achievements and talents)
2. **R**equires excessive admiration
3. **A**rrogant
4. **N**eeds to be special (and associate with other special or high-status people)
5. **D**reams of success, power, beauty, love (preoccupied with these fantasies)
6. **I**nterpersonally exploitative
7. **O**thers (lacks empathy, unable to recognize feelings/needs of others)
8. **S**ense of entitlement
9. **E**nvious (or believes others are envious)

Antisocial Personality Disorder (M: 2-4%, F: 0.5-1%)
Lack of remorse for actions, manipulative and deceitful, often violate the law. May appear charming on first impression. Pervasive pattern of disregard for others and violation of others' rights must be present before age 15; however, for the diagnosis of ASPD patients must be at least 18. Must have evidence of conduct disorder before age 15, history of trauma/abuse common (see *Child Psychiatry*, PS44)
Diagnosis requires 3+ of: **CORRUPT**
1. **C**annot conform to law and/or social norms (repeated illegal acts)
2. **O**bligations ignored (irresponsible)
3. **R**eckless disregard for safety of self or others
4. **R**emorseless
5. **U**nderhanded (deceitful; conning others for personal profit or pleasure)
6. **P**lanning insufficient (impulsive)
7. **T**emper (irritable and aggressive)

Histrionic Personality Disorder (2% of general population)
Attention-seeking behaviour and excessively emotional. Are dramatic, flamboyant, and extroverted. Cannot form meaningful relationships. Often sexually inappropriate. Diagnosed more in females but studies suggest equal prevalence
Diagnosis requires 5+ of: **ACTRESSS**
1. **A**ppearance used to attract attention
2. **C**entre of attention (else uncomfortable)
3. **T**heatrical
4. **R**elationships (believed to be more intimate than they are)
5. **E**asily influenced
6. **S**eductive behaviour
7. **S**hallow expression of emotions (which rapidly shift)
8. **S**peech (impressionistic and vague)

Table 10. Description and Diagnosis of Personality Disorders

Cluster C: "Sad" Personality Disorders
- Patients seem anxious, fearful
- Familial association with anxiety disorder
- Common defense mechanisms: isolation, avoidance, hypochondriasis

Avoidant Personality Disorder (2.4% of general population)
Timid and socially awkward with a pervasive sense of inadequacy, social inhibition, and hypersensitivity to criticism. Fear of embarrassing or humiliating themselves in social situations so remain withdrawn and socially inhibited
Diagnosis requires 4+ of: **CRINGES**
1. **C**riticism or rejection preoccupies thoughts in social situations
2. **R**estraint in relationships due to fear of being shamed
3. **I**nhibited in new relationships due to fear of inadequacy
4. **N**eeds to be sure of being liked before engaging socially
5. **G**ets around occupational activities requiring interpersonal contact
6. **E**mbarrassment prevents new activity or taking risks
7. **S**elf-viewed as unappealing or inferior

Obsessive-Compulsive Personality Disorder (2.1-7.9%)
Preoccupation with orderliness, perfectionism, and mental and interpersonal control. Is inflexible, closed-off, and inefficient
Highly comorbid with mood/anxiety and eating disorders
Diagnosis requires 4+ of: **SCRIMPER**
1. **S**tubborn
2. **C**annot discard worthless objects
3. **R**ule/detail obsessed (to point of activity lost)
4. **I**nflexible in matters of morality, ethics, values
5. **M**iserly
6. **P**erfectionistic to the extent that it hampers task completion
7. **E**xcludes leisure due to devotion to work
8. **R**eluctant to delegate to others

Dependent Personality Disorder (0.5-0.6% of general population)
Pervasive and excessive need to be taken care of, excessive fear of separation, clinging and submissive behaviours. Difficulty making everyday decisions. Useful to set regulated treatment schedule (regular, brief visits) and being firm about in between issues. Encourage patient to do more for themselves, engage in own problem-solving
Diagnosis requires 5+ of: **RELIANCE**
1. **R**eassurance and/or advice required for everyday decisions (excessive)
2. **E**xpressing disagreement difficult
3. **L**ife responsibilities assumed by others
4. **I**nitiating projects difficult (because lack of self-confidence)
5. **A**lone (feels helpless and uncomfortable when alone)
6. **N**urturance (goes to excessive lengths to obtain)
7. **C**ompanionship sought urgently
8. **E**xaggerated fears of being left to care for self

Table 11. Key Differences Among Schizoid, Schizotypal, and Schizophrenia

	Schizoid	Schizotypal	Schizophrenia
Thought Form	Organized	Organized, but vague and circumstantial	Disorganized, tangential, loosening of associations
Thought Content	No psychosis	No psychosis; may have ideas of reference, paranoid ideation, odd beliefs, and magical thinking	Psychosis
Relationships	Solitary, NO desire for social relationships	Lacks close relationships, INTERESTED in relationships but has difficulty forming them	Socially marginalized, but not by choice

OCPD vs. OCD

	OCPD	OCD
Ego-Syntonic or Ego-Dystonic	Ego-syntonic	Ego-dystonic
Thought Content	Obsessional thinking, no compulsions, strict routine and rigidity in day-to-day matters, more perfectionistic and rigid	Obsessions and compulsions, rituals, anxiety provoking unwanted intrusive thoughts

Child Psychiatry

Developmental Concepts

- temperament: a child's innate psycho-physiological and behavioural characteristics (i.e. emotionality, activity, and sociability); spectrum from "difficult" to "slow-to-warm-up" to "easy temperament"
- parental fit: the congruence between parenting style (authoritative, permissive) and child's temperament
- attachment: special relationship between child and primary caretaker(s); develops during first year, the caretaker's attachment style is the best predictor of their child's attachment style, see Table 12
- separation anxiety (normal between 10-18 mo): where separation from attachment figure results in distress

Table 12. Attachment Models

Parent/Caregiver	Attachment Type	Features in Child (during Strange Situation experiment)
Loving, consistently available, sensitive, and receptive	Secure	Freely explores and engages with strangers well (as long as mother in close proximity), upset with caregiver's departure, happy with return
Rejecting, unavailable psychologically, insensitive responses	Insecure (avoidant)	Ignores caregiver, shows little emotion with arrival or departure, little exploration
Inconsistent, insensitive responses, role reversal	Insecure (ambivalent/resistant)	Clingy but inconsolable, often displays anger or helplessness, little exploration
Frightening, dissociated, sexualized, or atypical **Often history of trauma or loss**	Disorganized	Simultaneous approach/avoidance and stress-related straining behaviour

Consider speaking to children alone. Always consider child abuse in your DDx.
See Paediatrics, P18

Tips for the Child Interview
- Use language the child will understand (e.g. don't ask about feelings of worthlessness, ask about whether they feel like they are a bad kid)
- Use developmentally-appropriate questions (e.g. don't ask about lack of interest in activities, ask children whether they feel bored)

Mood Disorders in Children and Adolescents

MAJOR DEPRESSIVE DISORDER

HEEADSSS Interview
Home environment
Education/Employment
Eating
Activities
Drugs
Sex
Safety
Suicide/depression

Epidemiology
- lifetime prevalence for pre-pubertal 1-2% (F:M=1:1); adolescents 4-18% (F:M=2:1)

Clinical Features
- only difference in diagnostic criteria for children and adolescents is that irritable mood may replace depressed mood
- physical features: insomnia (children), hypersomnia (adolescents), somatic complaints, substance misuse, decreased hygiene
- psychological features: irritability, boredom, anhedonia, low self-esteem, deterioration in academic performance, social withdrawal, lack of motivation, listlessness
- common comorbid diagnoses: anxiety, ADHD, ODD, conduct disorder, eating disorders, and substance misuse

Treatment
- majority never seek treatment
- supportive therapy including psychoeducation, active listening, and lifestyle advice helpful in mild depressive episode
- CBT or IPT, internet-based therapy if in-person options unavailable
- 1st line SSRI: fluoxetine
- 2nd line SSRIs: escitalopram, sertraline, citalopram
- close follow-up for adolescents starting SSRIs to monitor for increased suicidal ideation or behaviour
- in severe depression, best evidence for combined pharmacotherapy and psychotherapy
- ECT or rTMS: limited evidence in this population, only for use in adolescents ≥12 y/o with severe illness, psychotic features, catatonic features, persistently suicidal
- light therapy, self-help books, and applications can be used as adjuncts

Prognosis
- prolonged episodes, up to 1-2 yr = poor prognosis
- prognosis variable; adolescents with depression more likely to have depression in adulthood than adolescents without
- approximately 2% of adolescents with depression will develop bipolar disorder within 4 yr
- complications: negative impact on family and peer relationships, school failure, significantly increased risk of suicide attempt or completion (however, suicide risk low for pre-pubertal children), substance use disorder

DISRUPTIVE MOOD DYSREGULATION DISORDER

Clinical Features
- severe, developmentally inappropriate, recurrent verbal or behavioural temper outbursts at least 3x/wk with persistently irritable mood in between
- symptom onset before age 10, occurring for ≥12 mo, in ≥2 settings, with no more than 3 consecutive mo free from symptoms
- diagnosis should be made between ages 6-18
- criteria not met for intermittent explosive disorder nor bipolar disorder (no mania/hypomania)
- supersedes diagnosis of ODD if criteria for both are met
- common comorbidities: ADHD, anxiety disorders, depressive disorders

BIPOLAR DISORDER

Clinical Features
- mixed presentation and psychotic symptoms (hallucinations and delusions) more common in adolescent population than adult population
  - often misdiagnosed in the adolescent population
- unipolar depression may be an early sign of adult bipolar disorder
- associated with rapid onset of depression, psychomotor retardation, mood-congruent psychosis, affective illness in family, and pharmacologically-induced mania

Treatment
- lack of research in adolescent population, treatment guidelines based off of adult recommendations
- pharmacotherapy: mood stabilizers (lithium, anticonvulsants) and/or antipsychotics (risperidone, olanzapine, quetiapine, aripiprazole)
- psychotherapy: CBT, family-focused therapy (a therapeutic modality designed for bipolar disorder that combines psychoeducation, communication skills training, and problem-solving skills training)

Anxiety Disorders in Children and Adolescents

- prevalence 10% in childhood/adolescence; F:M=2:1
- often not recognized

Clinical Features
- becomes problematic when it interferes with typical academic/social functioning
- children and adolescents may not vocalize their anxiety but instead exhibit behavioural manifestations
- associated with school problems, unrealistic worries, physical/somatic symptoms (abdominal pain, headaches), social and relationship problems, social withdrawal and isolation, sleep difficulties, tearful episodes or temper tantrums, lack of confidence, irritability and mood symptoms, alcohol and drug use in adolescents
- tension may look like fidgeting

Differential Diagnosis
- depressive disorders, ODD, truancy
- persistence and impairment to daily functioning differentiates anxiety disorder from normal anxiety
- for school avoidance, differentiate social anxiety (fear of performance and humiliation) from generalized anxiety
- consider anxiety about separation, and rule out bullying and school refusal due to learning disorder

Course and Prognosis
- better prognosis with later age of onset, fewer comorbidities, early initiation of treatment, ability to maintain school attendance and peer relationships, and absence of social anxiety disorder
- with treatment, up to 80% of children will not meet criteria for their anxiety disorder at 3 yr follow-up, but up to 30% will meet criteria for another psychiatric disorder

Treatment
- similar principles for most childhood anxiety disorders due to overlapping symptomatology and frequent comorbidity
- psychoeducation of child and family
- psychotherapy: CBT has been shown to be effective in children and adolescents with anxiety
- pharmacotherapy: SSRIs can be helpful

SEPARATION ANXIETY DISORDER
- excessive and developmentally inappropriate anxiety on real, threatened, or imagined separation from attachment figures or home, with physical or emotional distress for at least 4 wk
- persistent worry about losing attachment figures or experiencing an untoward event to self; reluctance to go places, be alone, or sleep alone; nightmares involving separation; physical symptoms when separated
- often associated with school refusal, comorbid major depression

SOCIAL ANXIETY DISORDER (SOCIAL PHOBIA)
- anxiety, fear, and/or avoidance provoked by situations where child feels under the scrutiny of others
- must distinguish between shy child, child with issues functioning socially (e.g. autism), and child with social anxiety
  - diagnosis only if anxiety interferes significantly with daily routine, social life, academic functioning, or if markedly distressed. Must occur in settings with peers, not just adults
- features: crying, tantrums, freezing, clinging behaviour, mutism, excessively timid, stays on periphery, refuses to be involved in group play
- significant implication for future quality of life if untreated; lower levels of satisfaction in leisure activities, higher rates of school dropout, poor workplace performance, increased rates of remaining single

SELECTIVE MUTISM
- consistent failure to speak in specific social situations where speaking is expected, despite speaking in other situations for ≥1 mo
- the disturbance interferes with educational or occupational achievement or with social communication
- not due to lack of knowledge of language or communication disorder

GENERALIZED ANXIETY DISORDER
- diagnostic criteria same as adults (note: only 1 item is required in children for Criteria C)
- children worry about many things (e.g. school, future, family, past)
- often redo tasks, show dissatisfaction with their work, and tend to be perfectionistic
- often fearful in multiple settings and expect more negative outcomes when faced with academic or social challenges, and require reassurance and support to take on new tasks

Attachment type can be assessed in infants 10-18 mo of age using the Strange Situation test, in which the child is stressed by the caregiver being removed from the situation and the stranger staying. Attachment style is measured by the child's behaviour during the reunion with the caregiver

Attachment problems may present as a child who is difficult to soothe, has difficulty sleeping, problems feeding, tantrums, or behavioural problems

The shy child is quiet and reluctant to participate but slowly 'warms up'

Fluoxetine, Cognitive-Behavioural Therapy and Their Combination for Adolescents with Depression: Treatment for Adolescents with Depression Study (TADS) Randomized Controlled Trial

JAMA 2004;292:807-820

Purpose: To evaluate effectiveness of fluoxetine alone, cognitive behavioural therapy (CBT) alone, CBT with fluoxetine, and placebo among adolescents with major depressive disorder (MDD).

Methods: Randomized controlled trial at 13 US academic and community clinics between spring 2000-summer 2003, including patients 12-17 y/o with a primary DSM IV diagnosis of MDD assigned to one of the aforementioned four treatment arms. The primary outcome was the Children's Depression Rating Scale-Revised (CDRSR) total score.

Results: Fluoxetine with CBT had a statistically significant CDRSR score as compared to placebo (P=0.001) with a 71% response rate. This combination was greater than fluoxetine alone (P=0.02), and CBT alone (P=0.01). Fluoxetine alone was greater than CBT alone (P=0.01).

Conclusion: Combination of fluoxetine with CBT offered the most favourable benefit-risk tradeoff for adolescents with MDD.

SPECIFIC PHOBIA
- common phobias in childhood: fear of heights, small animals, physicians, dentists, darkness, loud noises, thunder, lightning

OCD
- diagnostic criteria same as adults
- note: young children may not be able to articulate the aims of their compulsions

Neurodevelopmental Disorders

Autism Spectrum Disorder

Diagnosis
- persistent deficits in social communication and interaction, manifested in three areas:
  - **social-emotional reciprocity**: abnormal social approach and failure of normal back-and-forth conversation; reduced sharing of interests, emotions, or affect; failure to initiate or respond to social interactions
  - **nonverbal communicative behaviours**: poorly integrated verbal and nonverbal communication; abnormalities in eye contact and body language or deficits in understanding and use of gestures; total lack of facial expressions and nonverbal communication
  - **developing, maintaining, and understanding relationships**: difficulties adjusting behaviour to suit various social contexts; difficulties in sharing imaginative play or in making friends; absence of interest in peers
- restricted, repetitive patterns of behaviour, interests, or activities manifested by ≥2 of: stereotyped or repetitive motor movements, insistence on sameness, highly restricted fixated interests, hyper-/hypo-reactivity to sensory input
- symptoms must be present in early developmental period
- symptoms cause clinically significant impairment in social, occupational, or other important areas of current functioning
- not better explained by intellectual disability or global developmental delay
- **specifiers**
  - current severity: requiring very substantial support, requiring substantial support, requiring support
  - ± language impairment, ± intellectual impairment, ± catatonia
  - associated with known medical or genetic condition or environmental factor

Differential Diagnosis
- neurodevelopmental: global delay, intellectual disability, language disorder, social communication disorder, learning disorder, developmental coordination disorder, stereotypic movement disorder
- mental and behavioural: ADHD, mood disorder, anxiety disorder, selective mutism, attachment disorder, ODD, conduct disorder, OCD, childhood schizophrenia
- conditions with developmental regression: Rett syndrome, epileptic encephalopathy (Landau-Kleffner)
- other: hearing/visual impairment, abuse

Treatment
- team-based: school, psychologist, occupational therapist, physiotherapist, speech-language pathologist, paediatrics, psychiatry
- psychosocial: family education and support, school programming, behavioural therapy, social skills training
- treat concomitant disorders such as ADHD, tics, OCD, anxiety, depression, and seizure disorder
- adjunctive pharmacotherapy (does not treat ASD itself): atypical antipsychotics (for irritability, aggression, agitation, self-mutilation, tics), SSRIs (for anxiety, depression), stimulants (for associated inattention and hyperactivity)

Prognosis
- variable, but improves with early intervention

Attention Deficit Hyperactivity Disorder

- prevalence: 5-12% of school-aged children; M:F=4:1, although girls may be under-diagnosed
- girls tend to have inattentive symptoms; boys tend to have impulsive/hyperactive symptoms

Etiology
- genetic: 75% heritability, dopamine candidate genes DAT1, DRD4
- neurobiology: decreased catecholamine transmission, low prefrontal cortex (PFC) activity, increased β activity on EEG
- cognitive: developmental disability, poor inhibitory control, and other errors of executive function

Efficacy and Safety of Selective Serotonin Reuptake Inhibitors, Serotonin-Norepinephrine Reuptake Inhibitors, and Placebo for Common Psychiatric Disorders Among Children and Adolescents: A Systematic Review and Meta-Analysis

JAMA Psychiatry 2017;74(10):1011-1020

Purpose: Examine the relative efficacy and safety of SSRIs, SNRIs, and placebo for the treatment of depressive disorders (DDs), anxiety disorders (ADs), obsessive-compulsive disorder (OCD), and posttraumatic stress disorder (PTSD) in children and adolescents.

Methods: Meta-analysis of RCTs regarding use of SSRIs or SNRIs in youths with DD, AD, OCD, or PTSD. Effect sizes, calculated as standardized mean differences (Hedges g) and risk ratios (RRs) for adverse events, were assessed in a random-effects model.

Results: Thirty-six trials were eligible and analysis showed that SSRIs and SNRIs were more beneficial compared with placebo (g = 0.32; 95% CI, 0.25-0.40; P < .001). ADs (g = 0.56; 95% CI, 0.40-0.72; P < .001) had larger between-group effect sizes than DDs (g = 0.20; 95% CI, 0.13-0.27; P < .001). Patients with DDs exhibited significantly larger placebo responses (g = 1.57; 95% CI, 1.36-1.78; P < .001) compared with those with ADs (g = 1.03; 95% CI, 0.84-1.21; P < .001). The SSRIs produced a relatively large effect size for ADs (g = 0.71; 95% CI, 0.45-0.97; P < .001). Patients receiving an antidepressant vs. a placebo reported significantly more treatment-emergent adverse events (RR, 1.07; 95% CI, 1.01-1.12; P = .01 or RR, 1.49; 95% CI, 1.22-1.82; P < .001, depending on the reporting method), severe adverse events (RR, 1.76; 95% CI, 1.34-2.32; P < .001), and study discontinuation due to adverse events (RR, 1.79; 95% CI, 1.38-2.32; P < .001).

Conclusion: Compared with placebo, SSRIs and SNRIs are more beneficial than placebo in children and adolescents; however, the benefit is small and disorder specific, yielding a larger drug-placebo difference for AD than for other conditions. Response to placebo is large, especially in DD. Severe adverse events are significantly more common with SSRIs and SNRIs than placebo.

Diagnosis

- diagnosis requires: onset before age 12, persistent symptoms ≥6 mo, symptoms present in ≥2 settings (i.e. home, school, work), interferes with academic, family, and social functioning, and is divided into 3 subtypes
  - combined type: ≥6 symptoms of inattention and ≥6 symptoms of hyperactivity-impulsivity
  - predominantly inattentive type: ≥6 symptoms of inattention
  - predominantly hyperactive-impulsive type: ≥6 symptoms of hyperactivity-impulsivity
  - for older adolescents and adults (≥ age 17), ≥5 symptoms required
- does not occur exclusively during the course of another psychiatric disorder
- DDx: learning disorders, hearing/visual defects, thyroid, atopic conditions, congenital problems (fetal alcohol syndrome, Fragile X), lead poisoning, history of head injury, traumatic life events (abuse)
- specify current severity (mild/moderate/severe); if in partial remission (past diagnosis, has not met full criteria >6 mo, still functional impairment present)

Table 13. Core Symptoms of ADHD (DSM-5)

Inattention	Hyperactivity	Impulsivity
Careless mistakes	Fidgets, squirms in seat	Blurts out answers before questions completed
Cannot sustain attention in tasks or play	Leaves seat when expected to remain seated	Difficulty awaiting turn
Does not listen when spoken to directly	Runs and climbs excessively	Interrupts/intrudes on others
Fails to complete tasks	Cannot play quietly	
Disorganized	"On the go", driven by a motor	
Avoids and/or dislikes tasks that require sustained mental effort	Talks excessively	
Loses things necessary for tasks or activities		
Distractible		
Forgetful		

Clinical Features

- difficult to differentiate from highly variable normative behaviour before age 4, but often identified upon school entry
- present across multiple settings - school, home, extracurricular
- rule out developmental delay, sensory impairments, genetic syndromes, encephalopathies, or toxins (alcohol, lead)
- increased risk of substance use disorder, depression, anxiety, academic failure, poor social skills, comorbid CD and/or ODD, adult ASPD
- associated with family history of ADHD, difficult temperamental characteristics

Treatment

- non-pharmacological: psychoeducation, behavioural management (e.g. parent training, classroom management, social skills training)
- pharmacological: 1st line: stimulants (methylphenidate, amphetamines); 2nd line: atomoxetine and guanfacine XR; 3rd line: clonidine, bupropion, imipramine
- for comorbid symptoms: antidepressants, antipsychotics
- psychosocial intervention is first line for children <6, whereas psychosocial intervention plus medication is considered first line for children ≥6

Prognosis

- 70-80% continue into adolescence, but hyperactive symptoms usually abate
- 65% continue into adulthood; secondary personality disorders and compensatory anxiety disorders are identifiable

Comparative Efficacy and Tolerability of Medications for Attention-Deficit Hyperactivity Disorder in Children, Adolescents, and Adults: A Systematic Review and Network Meta-Analysis
Lancet 2018;5:727-738
Purpose: Estimate the comparative efficacy and tolerability of oral medications for ADHD in children, adolescents, and adults.
Methods: Review of double-blind RCTs comparing amphetamines, atomoxetine, bupropion, clonidine, guanfacine, methylphenidate, and modafinil with each other or placebo.
Conclusions: Taking into account both efficacy and safety, evidence from this meta-analysis supports methylphenidate in children and adolescents, and amphetamines in adults, as preferred first-choice medications for the short-term treatment of ADHD.

Contrary to the concerns of many parents and health care providers, treatment with stimulant medications of ADHD in childhood does not increase the likelihood of substance misuse later in life

Disruptive, Impulse Control, and Conduct Disorder

Oppositional Defiant Disorder

- prevalence: 2-16%, M=F after puberty

Diagnosis

- pattern of negativistic/hostile and defiant behaviour for ≥6 mo, with ≥ 1 non-sibling, with ≥4 symptoms manifested in 3 areas of:
  - **angry/irritable mood**: easily loses temper, touchy or easily annoyed, often angry and resentful
  - **argumentative/defiant**: argues with adults/authority figure, defies requests/rules, deliberately annoys, blames others for their own mistakes or misbehaviour
  - **vindictiveness**: spiteful or vindictive twice in past 6 mo
  - **note**: difference between normal behaviour and ODD is frequency of symptoms (most days if age <5 yr, weekly if age ≥5 yr) exceeds what is normative for one's age gender, culture
- behaviour causes significant distress or impairment in social, academic, or occupational functioning
- behaviours do not occur exclusively during the course of a psychotic, substance use, or mood disorder
- severity (mild/moderate/severe) according to number of settings in which symptoms are present
- diagnosis of disruptive mood dysregulation disorder supersedes ODD if criteria for both are met

Clinical Features

- first symptoms usually appear during preschool and rarely later than early adolescence
- associated with poor school performance, few friends, strained parent/child relationships, risk of developing mood disorders later on, often precedes CD

Treatment

- parent: parent management training, psychoeducation for parents and family
- behavioural therapy: to teach, practice, and reinforce prosocial behaviour
- social: school/day-care interventions
- pharmacotherapy for comorbid disorders

Conduct Disorder

- prevalence: 1.5-3.4% (M:F=4:1)

Etiology

- parental/familial factors: parental psychopathology (e.g. ASPD, substance use disorder), child-rearing practices (e.g. child abuse, discipline), low socioeconomic status (SES), family violence
- child factors: difficult temperament, ODD, learning problems, ADHD, neurobiology

Diagnosis

- pattern of behaviour that violates rights of others and age appropriate social norms with ≥3 criteria noted in past 12 mo and ≥1 in past 6 mo:
  - aggression to people and animals: bullying, initiating physical fights, use of weapons, forced sex, cruel to people and/or animals, stealing while confronting a person (i.e. armed robbery)
  - destruction of property: arson, deliberately destroying others' property
  - deceitfulness or theft: breaking and entering, conning others, stealing nontrivial items without confrontation
  - violation of rules: out all night before age 13, often truant from school before age 13, runaway ≥2 times at least overnight or for long periods of time
  - disturbance causes clinically significant impairment in social, academic, or occupational functioning
  - if ≥18 yr, criteria not met for ASPD
- diagnostic types
  - childhood-onset (≥1 criterion prior to age 10)
  - adolescent-onset (no criteria until age 10)
  - unspecified onset (insufficient information)
  - mild, moderate, severe
- differential: ADHD, depression, head injury, substance misuse

Treatment

- early intervention necessary and more effective; long-term follow-up required
- psychosocial: parent management training, anger replacement training, CBT, family therapy, education/employment programs, social skills training
- pharmacotherapy for comorbid disorders

Children with ODD like "RATs and BEARS"

Rule breaker
Annoying
Temper

Blames others
Easily annoyed
Argues with adults
Resentful
Spiteful/vindictive

A Systematic Review and Analysis of Long-Term Outcomes in Attention Deficit Hyperactivity Disorder: Effects of Treatment and Non-Treatment
BMC Med 2012;10:99
Purpose: To determine the long-term outcomes of ADHD and whether there is an effect on long-term outcomes with treatment.
Methods: Systematic review of studies, including patients with diagnosed or symptomatic presentation of ADHD, assigned to pharmacological, non-pharmacological, multi-modal treatments, or a no-treatment control. Outcome measures included use/addictive behaviour, academic outcomes, antisocial behaviour, social function, occupation, self-esteem, driving outcomes, services use, and obesity.
Results: Untreated participants with ADHD had poorer outcomes vs. non-ADHD participants in 74% (n=244) of studies, while 26% (n=89) showed similar outcomes. 72% (n=37) of studies showed a benefit from ADHD treatment vs. untreated ADHD and 28% (n=15) showed no benefit. Treatment of ADHD was found to be beneficial in studies looking at driving (100%), obesity (100%), self-esteem (90%), social function (83%), academic outcomes (71%), drug use/addictive behaviour (67%), antisocial behaviour (50%), and occupation (33%).
Conclusion: Overall, people with ADHD have poorer long-term outcomes than controls (those without ADHD). For those with ADHD, treatment improves long-term outcomes.

Conduct Disorder Diagnosis

TRAP
Theft: breaking and entering, deceiving, non-confrontational stealing
Rule breaking: running away, skipping school, out late
Aggression: people, animals, weapons, forced sex
Property destruction

Prognosis
- poor prognostic indicators include: early-age onset, high frequency, variety of behaviours, pervasiveness (i.e. in home, school, community), comorbid ADHD, early sexual activity, substance misuse
- 50% of children with CD develop ASPD as adults

Intermittent Explosive Disorder

Diagnosis
- recurrent behavioural outbursts representing a failure to control aggressive impulses in children ages ≥6, manifested as either:
  - verbal or physical aggression that does not damage others or property, occurring ≥2 times per wk for 3 mo
  - 3 outbursts involving physical damage to another person, animal, or piece of property in the last 12 mo
- outbursts are out of proportion to triggers and are not premeditated/for primary gain
- outbursts cause clinically significant distress or impairment in occupation or interpersonal functioning, or financial/legal consequences

Psychotherapy

- treatment in which a person with mental or physical difficulties aims to achieve symptomatic relief through interactions with another person
- psychotherapy is delivered by a trained counsellor, social worker, nurse, psychologist, general practitioner, or psychiatrist
- various types of therapy exist based on diverse theories of human psychology and mental illness etiology

Freud's Personality Theory – Three Parts of the "Psyche"
- **id**: instinctual drives, unconscious
- **superego**: person's conscience, formed by societal/parental norms
- **ego**: Latin "I", sense of self, conscious actions, attempts to satisfy drives of id within confines of reality and demands of superego

Common Factors of Psychotherapy
- good evidence that effective psychotherapy creates observable changes in brain circuitry and connectivity, but these changes are different from those observed with successful pharmacologic and other treatment modalities
- studies suggest that up to 60-90% of therapy outcome is due to common factors with only 10-40% due to specific factors
- common factors are warmth (unconditional positive regard), accurate empathy, genuineness, goodness of fit, relationship with provider predicts positive outcomes

Table 14. Summary of Psychotherapeutic Modalities

Type	Indications	Approach, Technique, and Theory	Ideal Candidates	Duration
Supportive Therapy	Adjustment disorders, somatic symptoms and related disorders, severe psychotic or personality disorders Adjunct to pharmacologic management in most disorders	Uses empathy, validation, and reflection to facilitate adaptation and coping Help patients feel safe, secure, and encouraged	Individuals in crisis or with severe symptoms in acute or chronic settings	Variable (single session to years, though often short-intermittent)
Interpersonal Therapy	Mood disorders	Focuses on how interpersonal relationships impact symptoms 4 key problem areas addressed: 1. grief and loss, 2. role transitions, 3. conflict, 4. interpersonal deficits Break the interpersonal cycle: depression, self-esteem, social withdrawal	Individuals with depression or bipolar disorder with some insight and difficult social functioning Absence of severe psychotic process, personality disorder, or comorbid substance use disorder	Weekly sessions, 12-20 sessions
Cognitive Behavioural Therapy	Most mental health disorders including: mood, anxiety, OCD, personality, eating, substance use, psychotic disorders	Combines theory and method from cognitive and behavioural therapies to teach the patient to change connections between thinking patterns, habitual behaviours, and mood/anxiety problems Cognitive component includes using thought records to help monitor thoughts and identify inaccurate automatic thoughts Behavioural component includes techniques such as systematic desensitization (mastering anxiety-provoking situations by approaching them gradually and in a relaxed state that limits anxiety), flooding (confronting feared stimulus for prolonged periods until it is no longer frightening), positive reinforcement (strengthening behaviour and causing it to occur more frequently by rewarding it), negative reinforcement (causing behaviour to occur more frequently by removing a noxious stimulus when desired behaviour occurs), extinction (causing a behaviour to diminish by not rewarding it), and punishment/aversion therapy (causing a behaviour to diminish by applying a noxious stimulus)	Individuals with motivation to change and who are able to participate in homework	Typically weekly or twice weekly sessions, 12-20 sessions Maintenance therapy can be carried out over years
Dialectical Behavioural Therapy	Borderline personality disorder	Therapy that combines CBT techniques with Buddhist Zen mindfulness practices and dialectical philosophy Focuses on 4 types of skills: mindfulness, emotional regulation, interpersonal effectiveness, and distress tolerance Involves 4 components: individual therapy, group skills training, phone consultations, and a consultation team	Individuals with borderline personality disorder or borderline personality trait and severe problems of emotional dysregulation, impulsivity, or self-harm	Typically 1 yr Weekly individual and group therapy
Motivational Interviewing and Motivational Enhancement herapy	Substance use disorders Techniques can be applied to facilitate behavioural change in most psychological problems	Spirit of MI (CAPE): Compassion, Acceptance, Partnership, Evocation Principles of MI (RULE): Resist "righting reflex", Understand client and their reasons for change, Listen, Empower by conveying hope and supporting autonomy Techniques of MI (OARS): Open-ended questions, Affirmations to validate client, Reflections (the skill of accurate empathy), Summaries to help client organize self	Individuals with problematic substance use, maladaptive behaviour patterns (therapy disengagement, medication noncompliance, poor health habits)	Brief interventions (efficacy with as little as 15 min, single session), better result with more sessions Addiction is a chronic condition, often need boosters over time MET = 4 sessions
Group Psychotherapy	Most mental health disorders including mood, anxiety, OCD, personality, eating, substance use, and psychotic disorders can benefit from group therapy as part of treatment	Aims to promote self-understanding, acceptance, social skills	Adolescents, individuals not currently in crisis, absence of severe psychotic symptoms	Variable Often time-limited (e.g. weekly sessions for 12 wk)
Family Therapy	Most mental health disorders including mood, anxiety, OCD, personality, eating, substance use, and psychotic disorders can benefit from group therapy as part of treatment	Family system considered more influential than individual, especially for children Focus on here and now, re-establishing parental authority, strengthening normal boundaries, and rearranging alliances	Children and adolescents with families willing to engage in treatment	Often short-term (e.g. 12 sessions)
Mindfulness-based Cognitive Therapy/ Mindfulness-based Stress Reduction	Emerging evidence for treating adjustment disorder, MDD (relapse prevention), anxiety, pain disorders, insomnia, substance use disorder (relapse prevention)	Derived from Buddhist meditative and philosophical practices; aims to help people attend to thoughts, behaviours, and emotions in the moment and non-judgmentally using guided breathing exercises	Individuals who are motivated and willing to engage in therapy	Generally weekly sessions for 8 wk
Psychoanalytic/ Psychodynamic Therapy	Anxiety, obsessional thinking, conversion disorder, depression	Theory: exploration of meaning of early experiences and how they affect emotions and patterns of behaviour Recollection (remembering), repetition (reliving with the therapist), working through (gaining insight) Techniques: free association, dream interpretation, transference analysis	Psychologically minded, highly motivated, wish to understand selves and not just relieve symptoms Able to withstand difficult emotions without fleeing or self-destructive acts High level of function	Time intensive: Psychoanalysis: 4-5 times/wk for 3-7 yr Psychodynamically oriented therapy: 2-3 times/wk for fewer yr

Pharmacotherapy

Antipsychotics

- "antipsychotics" used to be called "neuroleptics"
- overall mechanism of action: functionally antagonize, to varying degrees, D2 activity in target brain pathways
- primarily indicated for psychotic symptoms in: schizophrenia and related disorders, manic episodes, depressive episodes, substance use, medical conditions (e.g. neoplasm)
- other uses: treatment-resistant MDD, severe GAD, complex PTSD, severe OCD, borderline PD, behavioural symptoms of dementia, delirium, Tourette syndrome, substance use disorder in dual diagnosis, Huntington's disease, ASD, and impulse control disorders
  - adjunctive management of agitation, aggression, severe anxiety, and severe sleep difficulties when sedative-hypnotics are contraindicated
- onset: acute, rapid calming effect and decrease in agitation; the antipsychotic effect with improvement in thought disorder, delusions, and hallucinations may take 1-4 wk
- rational use
  - no reason to combine two or more antipsychotics, although this is quite common in clinical practice
  - all antipsychotics are equally effective, except for clozapine (considered to be most effective in treatment-resistant schizophrenia)
  - atypical antipsychotics (i.e. second generation) are as effective as typical (i.e. first generation) antipsychotics but are thought to have better adverse effect profiles; main difference is lower risk of EPS and TD but more metabolic side effects (see sidebar)
  - choose a drug to which the patient has responded to in the past or that was used successfully in a family member
- route: PO, short-acting or long-acting depot IM injections, and sublingual; more recently there is inhaled loxapine mainly for use in acute agitation
- if no response in 4-6 wk, switch drugs
- duration: minimum 6 mo and usually for life in most patients with primary psychotic disorders; variable for other indications

Long-Acting Preparations

- antipsychotics formulated in oil for IM injection
- received on an outpatient basis
- indications: initially meant for individuals with schizophrenia or other chronic psychosis who relapse because of non-adherence, but current initial evidence suggests they are better than oral preparations overall
- should have been exposed to oral form prior to first injection
- dosing: start at low dosages, then titrate every 2-4 wk to maximize safety and minimize side effects
- side effects: similar to side effect profile to oral preparation of the same drug

Canadian Guidelines for the Treatment of Acute Psychosis in the Emergency Setting

- haloperidol 5 mg IM ± lorazepam 2 mg IM
- loxapine PO or IM 25 mg ± lorazepam 2 mg IM
- olanzapine 2.5-10 mg (PO, IM, oral quick dissolve – its time to peak is the same as regular PO)
- risperidone 2 mg (M-tab, liquid)

Dopamine Pathways Affected by Antipsychotics

Pathway	Effects	Associated Pathology
Mesolimbic	Emotion origination, reward	HIGH dopamine causes positive symptoms of schizophrenia (delusions, hallucinations)
Mesocortical	Cognition, executive function	LOW dopamine causes negative symptoms of schizophrenia
Nigrostriatal	Movement	LOW dopamine causes EPS
Tubero-infundibular	Prolactin hormone release	LOW dopamine causes hyper-prolactinemia

Typical (First Generation) vs. Atypical (Second Generation) Antipsychotics

	Typical	Atypical
Mechanism	Block postsynaptic dopamine receptors (D2)	Block postsynaptic dopamine receptors (D2) Block serotonin receptors (5-HT2) on presynaptic dopaminergic terminals, triggering DA release, and reversing DA blockade in some pathways. Some are partial D2 agonists
Pros	Inexpensive Plenty of injectable forms available	EPS less prevalent Low-risk of tardive syndromes Mood stabilizing effects
Cons	EPS more prevalent, including tardive syndromes in long-term Not mood stabilizing	Expensive Few injectable forms available Metabolic side effects (weight gain, hyperglycemia, lipid abnormalities, metabolic syndrome) Exacerbation (or new onset) of obsessive behaviour

Anticholinergic Effects

Red	as a	beet
Hot	as a	hare
Dry	as a	bone
Blind	as a	bat
Mad	as a	hatter

Table 15. Common Antipsychotic Agents

	Starting Dose	Maintenance	Maximum	Relative Potency (mg)
Typicals (in order of potency from high to low)				
Haloperidol (Haldol®)	2-5 mg IM q4-8 h 0.5-5 mg PO B/TID 0.2 mg/kg/d PO	Based on clinical effect	20 mg/d PO	2
Fluphenazine enanthate (Moditen®, Modecate® for IM formulation)	2.5-10 mg/d PO	1-5 mg PO QHS 25 mg IM/SC q1-3 wk	20 mg/d PO	2
Zuclopenthixol HCl (Clopixol®)	20-30 mg/d PO	20-40 mg/d PO	100 mg/d PO	4
Zuclopenthixol acetate (Acuphase®)	50-150 mg IM q48-72 h		400 mg IM (q2 wk)	
Zuclopenthixol decanoate (Cloxipol Depot®)	100 mg IM q1-4 wk	150-300 mg IM q2 wk	600 mg IM/wk	
Perphenazine (Trilafon®)	8-16 mg PO B/TID	4-8 mg PO T/QID	64 mg/d PO	10
Loxapine HCl (Loxitane®)	10 mg PO TID 12.5-50 mg IM q4-6 h	60-100 mg/d PO	250 mg/d PO	10
Chlorpromazine (Largactil®)	10-25 mg PO B/T/QID	400 mg/d PO	1000 mg/d PO	100
Atypicals (in order of potency from high to low)				
Risperidone (Risperdal®, Risperdal Consta® for IM long acting preparation, Risperdal® M-Tab for melting form – placed on tongue)	1-2 mg once daily/BID	4-8 mg/d PO 25 mg IM q2 wk	8 mg/d PO	2
Paliperidone (Invega®, Invega Sustenna® (one v) or Trinza® (three months) for IM long acting preparations)	3 mg/d PO	3-12 mg /d PO	12 mg/d PO	4
Olanzapine (Zyprexa®, Zyprexa Zydis® for melting form – placed on tongue)	5 mg/d PO	10-20 mg/d PO	30 mg/d PO	5
Asenapine (Saphris®)	5 mg SL BID	5-10 mg SL BID	10 mg SL BID	5
Ziprasidone (Zeldox®)	20 mg PO BID	40-80 mg PO BID	160 mg/d PO	6
Aripiprazole (Abilify®)	10-15 mg/d PO	10-15 mg/d PO	30 mg/d PO	7.5
Quetiapine (Seroquel®, Seroquel XR® for extended release®)	25 mg PO BID	400-800 mg/d PO	800 mg/d PO	75
Clozapine (Clozaril®)	25 mg PO BID	300-600 mg/d PO	900 mg/d PO	100

See Landmark Psychiatry Trials table for more information on CATIE, which details a comparison between first and second-generation antipsychotics in the treatment of schizophrenia.

Metabolic and Cardiovascular Adverse Effects Associated with Antipsychotic Drugs
Nat Rev Endocrinol 2012;8:114-126
All atypical antipsychotics can cause cardiovascular and metabolic side effects, such as obesity, dyslipidemia, hyperglycemia, and weight gain. Olanzapine and clozapine are most likely to cause these adverse effects. The mechanism that underlies the metabolic and cardiovascular effects is not fully understood. However, the histamine, dopamine, serotonin, and muscarinic receptors are implicated.

QTc prolongation is an important adverse effect of all antipsychotics; although not required, consider getting ECG prior to and after initiating new medication and to monitor QTc
Typicals: chlorpromazine and haloperidol warrant systematic baseline and follow-up ECG
Atypicals: ziprasidone has the highest risk among atypicals, clozapine also warrants systematic baseline and follow-up ECG

Features of Neuroleptic Malignant Syndrome

FARM
Fever
Autonomic changes (e.g. increased HR/BP, sweating)
Rigidity of muscles
Mental status changes (e.g. confusion)

FARM symptoms are also seen in serotonin syndrome (SS)
SS can be distinguished from NMS by the following:

SS	NMS
Twitchy, shivering, restless	Severe global rigidity
Flushed, sweaty	Pallor
Vomiting, diarrhea, abdominal pain	No GI symptoms

Table 16. Commonly Used Atypical Antipsychotics

	Risperidone (Risperdal®) / Paliperidone (Invega®)	Olanzapine (Zyprexa®, Zydis®)	Quetiapine (Seroquel®)	Clozapine (Clozaril®)	Aripiprazole (Abilify®)
Advantages	Lower incidence of EPS than typical antipsychotics at lower doses (<8 mg) Associated with less weight gain compared to clozapine and olanzapine	Better overall efficacy compared to haloperidol Well tolerated Low incidence of EPS and TD	Associated with slightly less weight gain compared to clozapine and olanzapine, but more than the other atypicals Mood stabilizing	Most effective for treatment-resistant schizophrenia Does not worsen tardive symptoms; may treat them Approximately 50% of patients benefit, especially paranoid patients and those with onset after 20 yr	Less weight gain and risk of metabolic syndrome compared to olanzapine and a lower incidence of EPS compared to haloperidol Mood stabilizing
Disadvantages relative to other SGAs	Highest risk of EPS/TD among SGAs – avoid if high-risk for EPS or existing movement disorder or elderly Elevated prolactin - sexual dysfunction, galactorrhea, gynecomastia, menstrual disturbance, infertility	Weight gain and metabolic effects – avoid in DM Sedating – avoid if high-risk for falls or fracture	Sedating/orthostatic hypotension – avoid if high-risk for falls or fracture QT prolongation in high doses – caution if cardiac risk	Weight gain and metabolic effects- avoid in DM Sedating/orthostatic hypotension - avoid if high-risk for falls or fracture Potentially severe constipation - avoid if risk of fecal impaction or bowel perforation Cardiomyopathy – caution if existing heart disease Reduces seizure threshold - caution if seizure disorder Agranulocytosis (1%) – avoid in existing leukopenia/ neutropenia, requires ongoing CBC monitoring	Insomnia, akathisia
Comments	Quick dissolve (M-tabs), and long-acting (Consta®/ Invega Trinza®) formulations available	Quick dissolve formulation (Zydis®) used commonly in ER setting for better compliance (but does not act faster) Acute IM form available		Weekly blood counts for 6 mo, then q2 wk Do not use with other drugs that may cause bone marrow suppression due to risk of agranulocytosis	

Note: Risk of weight gain: Clozapine > Olanzapine > Quetiapine > Risperidone

Table 17. Side Effects of Antipsychotics

System	Side Effects
Anticholinergic	Dry mouth, urinary retention, constipation, blurred vision, confusional states
α-adrenergic Blockade	Orthostatic hypotension, erectile dysfunction, failure to ejaculate
Dopaminergic Blockade	Extrapyramidal syndromes, galactorrhea, amenorrhea, erectile dysfunction, weight gain
Anti-Histamine	Sedation, weight gain
Hematologic	Agranulocytosis (clozapine)
Hypersensitivity Reactions	Liver dysfunction, blood dyscrasias, skin rashes, neuroleptic malignant syndrome, altered temperature regulation (hypothermia or hyperthermia)
Endocrine	Metabolic syndrome
Cardiac	QT prolongation

Neuroleptic Malignant Syndrome

- psychiatric emergency
  - hypothesis: due to strong DA blockade; increased incidence with high potency and depot antipsychotics
- risk factors
  - medication factors: sudden increase in dosage, starting a new drug
  - patient factors: medical illness, dehydration, exhaustion, poor nutrition, external heat load, male, young adults
- clinical features
  - tetrad: mental status changes (usually occur first), fever, rigidity, autonomic instability
  - develops over 24-72 h
  - labs: increased creatine phosphokinase, leukocytosis, myoglobinuria
- treatment: supportive - discontinue antipsychotic drug, hydration, cooling blankets, dantrolene (hydantoin derivative, used as a muscle relaxant), bromocriptine (DA agonist)
- mortality: 5%

Extrapyramidal Symptoms

- incidence related to increased dose and potency
- acute (early-onset; reversible) vs. tardive (late-onset; often irreversible)

Table 18. Extrapyramidal Symptoms

	Dystonia	Akathisia	Parkinsonism	Dyskinesia
Acute or Tardive	Both	Both	Acute	Tardive
High-Risk Groups	Acute: young Asian and Black males	Older females	Older females	Older patients
Presentation	Sustained abnormal posture; torsions, twisting, contraction of muscle groups; muscle spasms (i.e. oculogyric crisis, laryngospasm, torticollis)	Motor restlessness; crawling sensation in legs relieved by walking; very distressing, increased risk of suicide and poor adherence	Tremor; rigidity (cogwheeling); akinesia; postural instability (decreased/absent arm-swing, stooped posture, shuffling gait, difficulty pivoting)	Purposeless, involuntary, constant movements that involve facial and mouth musculature; less commonly – the limbs; rarely, the diaphragm ("hiccups")
Onset	Acute: within 5 d Tardive: >90 d	Acute: within 10 d Tardive: >90 d	Acute: within 30 d	Tardive: >90 d, more commonly yr
Treatment	Acute: benztropine or diphenhydramine, usually IM	Acute: lorazepam, propranolol, benztropine, or diphenhydramine; best approach: reduce dose or change antipsychotic to lower potency	Acute: benztropine; reduce dosage or change antipsychotic to low potency atypical antipsychotic	Tardive: no good treatment; may try clozapine; discontinue drug or reduce dosage Recently the FDA approved valbenazine and deutetrabenazine for the treatment of tardive dyskinesia

Anticholinergic Agents

- types
  - benztropine (Cogentin®) 2 mg PO, IM, or IV once daily (1-6 mg)
  - diphenhydramine (Benadryl®) 25-50 mg PO/IM QID
- do not routinely prescribe with antipsychotics
  - give anticholinergic agents only if at high-risk for acute EPS or if acute EPS develops
- do not give these for tardive syndromes because they worsen the condition

Antidepressants

- onset of effect
  - relief of neuro-vegetative/physical symptoms: 1-3 wk
  - relief of emotional/cognitive symptoms: 2-6 wk
- tapering of most antidepressants is usually required to avoid withdrawal reactions; speed of taper is based on the medication's half-life and the patient's individual sensitivity (i.e. fluoxetine does not require a taper due to its long half-life; paroxetine and venlafaxine require a slower taper than sertraline or citalopram)
- must be vigilant over the first 2 wk of therapy; neuro-vegetative symptoms may start to resolve while emotional and cognitive symptoms may not (patients may be at risk for suicidal behaviour during this time, particularly in children/adolescents)
- treatment of bipolar depression
- patients with bipolar disorder (bipolar depression) should not be treated with an antidepressant as the first line treatment
  - patients with bipolar disorder should only be treated with an antidepressant if combined with a mood stabilizer or antipsychotic; monotherapy with antidepressants is not advisable as the depression can switch to mania
  - maintenance of patients with bipolar disorder with antidepressants is not advisable except in specific cases

Comparative Efficacy and Acceptability of 21 Antidepressant Drugs for the Acute Treatment of Adults with Major Depressive Disorder: A Systematic Review and Network Meta-Analysis
Lancet 2018;391:1357-1366
Purpose: Update of literature to compare and rank antidepressants for the acute treatment of adults with unipolar major depressive disorder (MDD).
Methods: Systematic review and network meta-analysis of RCTs.
Results: 522 trials were identified comprising 116477 participants. All antidepressants were more effective than placebo, with ORs ranging between 2.13 (95% credible interval (CrI) 1.89-2.41) for amitriptyline and 1.37 (1.16-1.63) for reboxetine. For acceptability, only agomelatine (OR 0.84, 95% CrI 0.72-0.97) and fluoxetine (0.88, 0.80-0.96) were associated with fewer dropouts than placebo, whereas clomipramine was worse than placebo (1.30, 1.01-1.68). When all trials were considered, differences in ORs between antidepressants ranged from 1.15 to 1.55 for efficacy and from 0.64 to 0.83 for acceptability. In head-to-head studies, agomelatine, amitriptyline, escitalopram, mirtazapine, paroxetine, venlafaxine, and vortioxetine were more effective than other antidepressants (range of ORs 1.19-1.96), whereas fluoxetine, fluvoxamine, reboxetine, and trazodone were the least efficacious drugs (0.51-0.84). For acceptability, agomelatine, citalopram, escitalopram, fluoxetine, sertraline, and vortioxetine were more tolerable than other antidepressants (range of ORs 0.43-0.77), whereas amitriptyline, clomipramine, duloxetine, fluvoxamine, reboxetine, trazodone, and venlafaxine had the highest dropout rates (1.30-2.32), 46 (9%).
Conclusion: All antidepressants were more efficacious than placebo in adults with MDD. Smaller differences between active drugs were found when placebo-controlled trials were included in the analysis.

Table 19. Common Antidepressants

Class	Drug	Daily Starting Dose (mg)*	Therapeutic Dose (mg)	Comments
SSRI	fluoxetine (Prozac®) fluvoxamine (Luvox®) paroxetine (Paxil®) sertraline (Zoloft®) citalopram (Celexa®) escitalopram (Cipralex®)	20 50-100 10 50 20 10	20-80 150-300 20-60 50-200 20-40 10-20	Useful for typical and atypical depression, seasonal depression, anxiety disorders, OCD, eating disorders All SSRIs have similar effectiveness but consider side effect profiles and half-lives Citalopram and escitalopram have the fewest drug interactions and are sleep-wake neutral Sertraline is the safest SSRI in pregnancy and breastfeeding Fluoxetine is the most activating SSRI (recommend taking in the AM) Fluoxetine does not require a taper due to long half-life and is the most used in children and adolescents as it has most evidence Fluvoxamine is sedating (should be taken in PM) and can be involved in many drug-drug interactions For OCD, aim for maximum doses, sometimes higher
SNRI	venlafaxine (Effexor®) desvenlafaxine (Pristiq®) duloxetine (Cymbalta®)	37.5-75 50 30	75-225 50-100 30-60	Useful for depression, anxiety disorders, neuropathic pain
NDRI	bupropion (Wellbutrin®)	100	300-450	Useful for depression, seasonal depression; not recommended for anxiety disorder treatment because of stimulating effects Causes less sexual dysfunction (may reverse effects of SSRIs/SNRIs), weight gain, and sedation Increased risk of seizures at higher doses Contraindicated with history of seizure, stroke, brain tumour, brain injury, closed head injury Important to specify formulation, as available in IR, SR, XL (longest)
TCA (3° Amines)	amitriptyline (Elavil®) imipramine (Tofranil®) clomipramine (Anafranil®)	25-50 25-50 25-50	150-300 150-300 100-250	Useful for OCD (clomipramine is gold standard), melancholic depression, can also be used in other types of depression and anxiety disorders Requires ECG monitoring Check blood levels if using higher dosage Highly lethal in overdose
TCA (2° Amines)	nortriptyline (Aventyl®) desipramine (Norpramin®)	25-50 25-50	75-150 150-300	Preferred to tertiary amines because of lower propensity for anticholinergic adverse effects Requires ECG monitoring Check blood levels if using higher dosage Highly lethal in overdose
MAOI	phenelzine (Nardil®) tranylcypromine (Parnate®)	15 20	60-90 10-60	Useful for moderate/severe depression that does not respond to other antidepressants; atypical depression; anxiety disorders Requires strict adherence to MAOI diet, (low tyramine)
RIMA	moclobemide (Manerix®)	300	300-600	Useful for some anxiety disorders (e.g. social phobia) and depression
NaSSA	mirtazapine (Remeron®)	15	15-45	Useful in depression with prominent features of insomnia, agitation, or cachexia
SPARI	vilazodone (Viibryd®)	10	10-40	Useful in those with constipation as diarrhea is a common side effect
Serotonin Receptor Modulator	vortioxetine (Trintellix®)	5	5-20	May improve cognitive function

*for depression (start with ½ this dose for treatment of anxiety disorders)
MAOI = monoamine oxidase inhibitors; NaSSA = noradrenergic and specific serotonergic agent; NDRI = norepinephrine and dopamine reuptake inhibitors; RIMA = reversible inhibition of MAO-A; SNRI = serotonin and norepinephrine reuptake inhibitors; SSRI = selective serotonin reuptake inhibitors; TCA = tricyclic antidepressants; SPARI = serotonin partial agonist and reuptake inhibitor

Treatment Approach for Depression

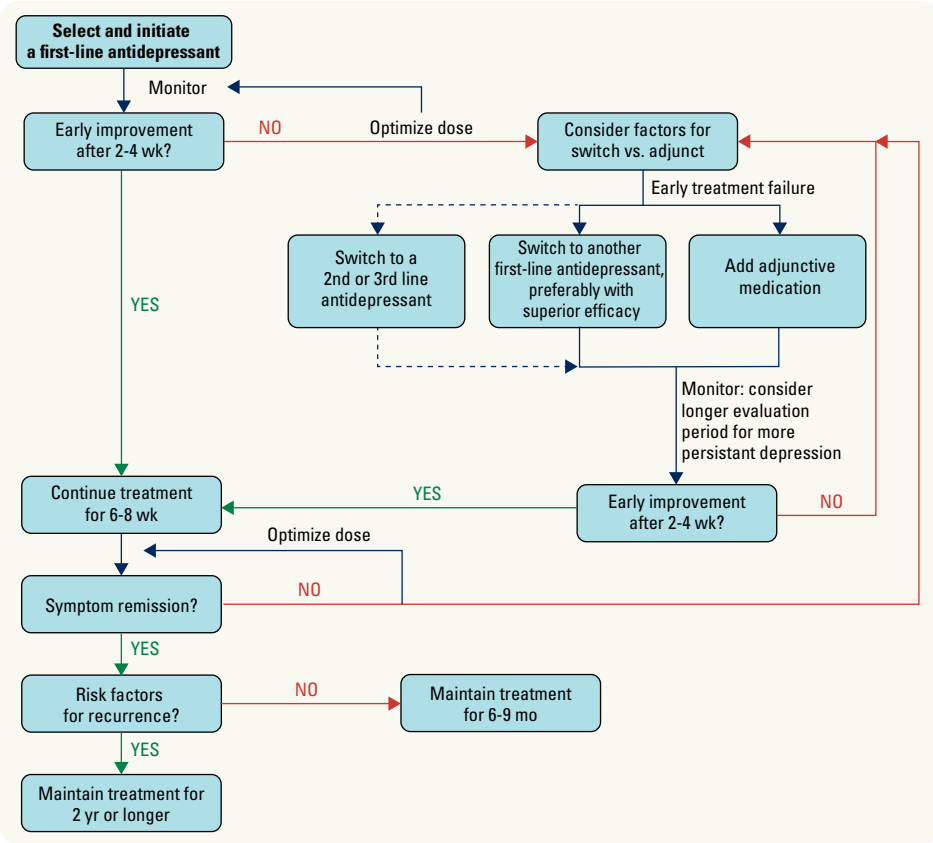

Figure 3. Depression treatment algorithm
Adapted from: Sidney H. Kennedy, Raymond W. Lam, Roger S. McIntyre, et al, The Canadian Journal of Psychiatry (61, 9), p. 21, copyright © 2020, Modified by Permission of SAGE Publications, Inc.

Psychopharmacology of SSRIs

Post-Synaptic Serotonin Receptor Stimulated	Effect/Side Effect
5HT1A centrally	Relief of depression Anxiolytic effect
5HT2A in spinal cord	Sexual dysfunction: delayed ejaculation, anorgasmia, decreased interest/ libido
5HT2C/5HT2A in brain	Activation: anxiety, insomnia Worst with fluoxetine, paroxetine Warn patients anxiety may worsen in first 1-2 wk of treatment
5HT3A in gut	GI upset: nausea, vomiting, bloating Take with food

- **optimization**: increase dosage to maximum tolerated or highest therapeutic dosage
- **augmentation**: the addition of a medication that is not considered an antidepressant to an antidepressant regimen (i.e. thyroid hormone, lithium, atypical antipsychotics (aripiprazole, quetiapine, olanzapine, risperidone))
- **combination**: the addition of another antidepressant to an existing treatment regimen (i.e. the addition of bupropion or mirtazapine to an SSRI or SNRI)
- **switch**: change of the primary antidepressant (within or outside a class)
- note: it is important to fully treat depression symptoms (i.e. to remission) to decrease relapse rates

Symptoms of Antidepressant Discontinuation (mainly from serotonin reuptake inhibition activity)

FINISH
Flu-like symptoms
Insomnia
Nausea
Imbalance
Sensory disturbances
Hyperarousal (anxiety/agitation)

Serotonin Syndrome

- thought to be due to over-stimulation of the serotonergic system
- can result from medication combinations such as more than one SSRI, SSRI + SNRI, SSRI or SNRI + MAOI, SSRI + tryptophan, MAOI + meperidine, MAOI + tryptophan
- rare but potentially life-threatening adverse reaction to SSRIs and SNRIs
- symptoms include: nausea, diarrhea, palpitations, chills, diaphoresis, restlessness, confusion, and lethargy but can progress to myoclonus, hyperthermia, rigor, and hypertonicity
- treatment: discontinue medication and administer emergency medical care as needed
- important to distinguish from NMS

Discontinuation Syndrome

- caused by the abrupt cessation of some antidepressants; most commonly with paroxetine, fluvoxamine, and venlafaxine (drugs with shortest half-lives)
- symptoms usually begin within 1-3 d and can include anxiety, insomnia, irritability, mood lability, N/V, dizziness, headache, dystonia, tremor, chills, fatigue, lethargy, and myalgia ("flu-like symptoms")
- treatment: symptoms may last between 1-3 wk, but can be relieved within 24 h by restarting antidepressant at the same dosage the patient was taking initially and initiating a slower taper over several weeks
- consider avoiding drugs with a short half-life

Table 20. Features of Commonly Used Antidepressant Classes

	SSRI	SNRI	TCA	MAOI	NDRI	RIMA	NaSSA	SPARI	Serotonin receptor modulator
Examples	fluoxetine, sertraline, citalopram	venlafaxine, duloxetine	amitriptyline, clomipramine	phenelzine	bupropion	moclobemide	mirtazapine	vilazodone	vortioxetine
Mode of Action	Block serotonin reuptake only	Block norepinephrine and serotonin reuptake	Block norepinephrine reuptake (clomipramine also blocks serotonin reuptake)	Irreversible inhibition of MAO A and B increases duration that NE, dopamine, and 5HT are in the synaptic cleft by preventing their degradation	Block norepinephrine and dopamine reuptake	Reversible inhibitor of monoamine oxidase A leads to increased duration of norepinephrine, dopamine, and 5HT in the synaptic cleft by preventing their degradation	Enhance central noradrenergic and serotonergic activity by inhibiting presynaptic α-2 adrenergic receptors	5HT1A partial agonism causes downregulation of presynaptic 5HT1A receptors to disinhibit serotonin release, and 5HT4 agonism treats constipation	5HT1A agonism downregulates presynaptic 5HT1A receptors to disinhibit serotonin release, and 5HT7 antagonism theoretically enhances cognitive function
Side Effects	CNS: restlessness, tremor, insomnia, headache, drowsiness, EPS GI: N/V, diarrhea, abdominal cramps, weight gain Sexual dysfunction: erectile dysfunction, anorgasmia CVS: increased HR, increased QTc, serotonin syndrome, SIADH, decreased platelet aggregation – increased risk of bleeding	Low dose side effects similar to SSRIs (serotonergic) Higher dose side effects: tremors, tachycardia, sweating, insomnia, orthostatic hypotension, increase in BP (noradrenergic) SIADH	Anticholinergic effects: (see Table 17, PS54) Noradrenergic effects: tremors, tachycardia, sweating α-1 adrenergic effects: orthostatic hypotension, falls QRS prolongation	Antihistamine effects (minimal): sedation, weight gain CVS: orthostatic hypotension, hypertensive crises with tyramine rich foods (e.g. wine, cheese), or combination with serotonergic or adrenergic medications, headache, flushes, reflex tachycardia, postural hypotension, insomnia Minimal anticholinergic effects	CNS: dizziness, headache, tremor, insomnia, agitation, anxiety, lower seizure threshold CVS: dysrhythmia, HTN GI: dry mouth, N/V, constipation, decreased appetite	CNS (usually minor): dizziness, headache, tremor, insomnia CVS: dysrhythmia, hypotension GI: dry mouth, N/V, diarrhea, abdominal pain, dyspepsia GU: delayed ejaculation Other: diaphoresis	CNS: sedation, dizziness Endocrine: increase in cholesterol, increase in triglycerides, weight gain GI: constipation, ALT elevation	CNS: sedation GI: nausea, diarrhea	GI: nausea
Risk in Overdose	Relatively safe in overdose	Tachycardia and N/V seen in acute overdose	Toxic in overdose 3 times therapeutic dose may be lethal Presentation: anticholinergic effects, CNS stimulation, then depression and seizures ECG: prolonged QRS and QTc (reflect severity) Treatment: activated charcoal, cathartics, supportive treatment, IV diazepam for seizure, physostigmine salicylate for coma Do not give ipecac, as can cause rapid neurologic deterioration and seizures	Toxic in overdose, but wider margin of safety than TCA	Tremors and seizures seen in overdose	Risk of fatal overdose when combined with SSRIs, SNRIs, or clomipramine	Relatively safe in overdose	Relatively safe in overdose	Relatively safe in overdose
Drug Interactions	MAOI, SNRI Some SSRIs (fluoxetine, fluvoxamine, paroxetine) strongly inhibit cytochrome P450 enzymes, therefore will affect levels of drugs metabolized by P450 system	MAOI, SSRI Low inhibition of cytochrome P450 compounds	MAOI, SSRI EtOH	Hypertensive crises with noradrenergic medications (i.e. TCA, decongestants, amphetamines) Serotonin syndrome with serotonergic drugs (i.e. SSRI, SNRI, tryptophan, dextromethorphan)	MAOI Drugs that reduce seizure threshold: antipsychotics, systemic steroids, quinolone antibiotics, antimalarial drugs	MAOI, paroxetine Opioids	MAOI, RIMA	MAOI	MAOI No inhibition of cytochrome P450

Mood Stabilizers

General Prescribing Information

- examples: lithium, divalproex, lamotrigine, carbamazepine
- used mainly for long-term stabilization of bipolar disorder, also used as first-line monotherapy or in conjunction with atypical antipsychotics for acute episodes of bipolar disorder (i.e. depression and mania)
- vary in their ability to "treat" (i.e. reduce symptoms acutely) or "stabilize" (i.e. prevent relapse and recurrence) manic and depressive symptoms; multi-agent therapy can be avoided in many patients but it is common
- before initiating, get baseline: CBC with differential and platelets, ECG (if patient >45 y/o or cardiovascular risk), BUN, creatinine, extended electrolytes, TSH, LFTs for divalproex and carbamazepine
- Also: screen for pregnancy, thyroid disease, neurological, renal, liver, cardiovascular diseases
- full effects may take 2-4 wk, thus may need acute coverage with benzodiazepines or antipsychotics

Specific Prescribing Information

- detailed pharmacological guidelines available online from the Canadian Network for Mood and Anxiety Treatments (CANMAT) and International Society for Bipolar Disorders (ISBD)
- for clinical information for treating bipolar disorder (see *Mood Disorders*, PS10)
- be mindful that divalproex and carbamazepine are teratogenic thus if prescribed for women at reproductive age, a reliable contraceptive strategy is required

Table 21. Commonly Used Mood Stabilizers

	Lithium	Lamotrigine (Lamictal®)	Divalproex (Epival®)	Carbamazepine (Tegretol®)
Indications	**1st line** Acute mania (monotherapy or with adjunct SGA) Bipolar I depression (monotherapy or in combination with divalproex, SSRI, or bupropion) Bipolar disorder maintenance (monotherapy or with adjunct SGA) **Other uses** Bipolar II depression Augmentation of antidepressants in MDD and OCD Schizoaffective disorder Chronic aggression, antisocial behaviour Recurrent depression	**1st line** Bipolar I depression (monotherapy) Bipolar disorder maintenance (limited efficacy in preventing mania, more effective when combined with lithium) **Other uses** Bipolar II depression Not recommended for acute mania	**1st line** Acute mania (monotherapy or with adjunct SGA) Bipolar I depression (combination with lithium or SSRI) Bipolar disorder maintenance (monotherapy or with adjunct SGA) **Other uses** Bipolar II depression Rapid cycling bipolar disorder Mixed phase/dysphoric mania	**2nd line** Acute mania (monotherapy) Bipolar disorder maintenance (monotherapy or in combination with lithium) **Other uses** Rapid cycling bipolar disorder
Mode of Action	Unknown Therapeutic response within 7-14 d	May inhibit 5-HT3 receptors May potentiate DA activity	Depresses synaptic transmission Raises seizure threshold	Depresses synaptic transmission Raises seizure threshold
Dosage	Adult: 600-1500 mg/d Geriatric: 150-600 mg/d Usually daily dosing Blood levels monitored and dose adjusted accordingly	Note: very slow titration required due to risk of Stevens-Johnson Syndrome Dose adjusted in patients taking other anticonvulsants such as divalproex Daily dose: 100-200 mg/d	750-2500 mg/d Usually daily dosing with ER preparation	400-1600 mg/d Usually BID or TID dosing
Therapeutic Level	Adult: 0.8-1.0 mmol/L (1.0-1.25 mmol/L for acute mania) Geriatric: 0.6-0.8 mmol/L	Therapeutic plasma level not established Dosing based on therapeutic response	17-50 mmol/L Same therapeutic levels as used for seizure prophylaxis (no data specific for mood stabilizing effect)	350-700 µmol/L Same therapeutic levels as used for seizure prophylaxis (no data specific for mood stabilizing effect)
Monitoring	Monitor serum levels every 5-7 d until therapeutic (always 12 h after dose) Then monitor monthly, then q2-3 mo Monitor thyroid function, creatinine q6 mo	Monitor for skin rash and suicidality when initiating treatment	Monitor serum levels every 5-7 d until therapeutic LFTs weekly x 1 mo, then monthly, then q2-3 mo due to risk of liver dysfunction Watch for signs of liver dysfunction: nausea, edema, malaise Check platelets and monitor levels to adjust dosage and confirm adherence	Monitor serum levels every 5-7 d until therapeutic Weekly blood counts for 1st mo, due to risk of agranulocytosis Watch for signs of blood dyscrasias: fever, rash, sore throat, easy bruising
Side Effects	GI: N/V, diarrhea, stomach pain GU: polyuria, polydipsia, nephrogenic diabetic insipidus, glomerulonephritis, renal failure, decreased glomerular filtration rate CNS: fine tremor, headache, fatigue, lethargy Hematologic: reversible benign leukocytosis Other: teratogenic (Ebstein's anomaly), hypothyroidism, weight gain, edema, worsening of psoriasis, bradycardia, ECG changes	Skin: rash (consider discontinuing due to risk of Steven-Johnson syndrome which is an emergency), slow dose titration to reduce risk Otherwise, usually well tolerated (GI: N/V, diarrhea CNS: ataxia, dizziness, diplopia, headache, somnolence Other: anxiety)	GI: liver dysfunction, N/V, diarrhea CNS: ataxia, drowsiness, tremor, sedation, cognitive blurring Other: hair loss, weight gain, thrombocytopenia, neural tube defects when used in pregnancy, polycystic ovarian syndrome	GI: N/V, diarrhea, hepatic toxicity CNS: ataxia, dizziness, slurred speech, drowsiness, confusion, nystagmus, diplopia Hematologic: transient leukopenia (10%), rare agranulocytosis, aplastic anemia Skin: rash (5% risk; consider discontinuing drug because of risk of Stevens-Johnson syndrome) Other: neural tube defects when used in pregnancy
Interactions	NSAIDs, thiazides, ACEI, and metronidazole decrease clearance, risk for lithium toxicity		OCP	OCP

Lithium Toxicity

- clinical diagnosis as toxicity can occur at therapeutic levels
- common causes: overdose, sodium/fluid loss, concurrent medical illness or initiation of NSAIDs, diuretics, or ACEI
- clinical features
  - GI: severe nausea/vomiting and diarrhea
  - cerebellar: ataxia, slurred speech, lack of coordination
  - cerebral: drowsiness, myoclonus, tremor, upper motor neuron signs, seizures, delirium, coma
- management
  - discontinue lithium for several days and begin again at a lower dose when lithium level has fallen to a non-toxic range
  - monitor serum lithium levels, creatinine, BUN, electrolytes
  - IV saline
  - hemodialysis if lithium >2 mmol/L, coma, shock, severe dehydration, failure to respond to treatment after 24 h, or deterioration

Long-term lithium use can lead to a nephropathy and diabetes insipidus in some patients

Anxiolytics

- anxiolytics mask or alleviate symptoms
- **indications**
  - short-term treatment of anxiety disorders, insomnia, alcohol withdrawal (especially delirium tremens), barbiturate withdrawal, akathisia due to antipsychotics, seizure disorders, musculoskeletal disorders, agitation or aggression associated with acute mania, or psychosis
- **relative contraindications**
  - major depression (except as an adjunct to other treatment), history of drug/alcohol misuse, caution in pregnancy/breastfeeding
  - myasthenia gravis is a relative contraindication for benzodiazepines
- **mechanism of action**
  - benzodiazepines: potentiate binding of GABA to its receptors; results in decreased neuronal activity
  - buspirone: partial agonist of 5-HT1A receptors

Benzodiazepine Antagonist – Flumazenil (Anexate®)
Use for suspected benzodiazepine overdose
Specific antagonist at the benzodiazepine receptor site

Benzodiazepines

- should be used for limited periods (i.e. days-weeks) to avoid tolerance and dependence
- all benzodiazepines are sedating, decrease respiratory drive, and increase risk for falls, confusion, and motor vehicle accidents; be wary with use in the elderly, especially in combination with other psychotropic medications
- have similar efficacy, so choice depends on half-life, metabolites, and route or schedule of administration
- taper slowly over weeks-months because they can cause withdrawal reactions (see below)
- beware of use with alcohol and other CNS depressants because of potentiation of CNS depression; caution with drinking and driving/machinery use
- **side effects**
  - CNS: drowsiness, cognitive impairment, reduced motor coordination (falls), memory impairment
  - dependence, tolerance, withdrawal
- **withdrawal**
  - low dose withdrawal symptoms: tachycardia, HTN, panic, rebound insomnia, anxiety, impaired memory and concentration, perceptual disturbances
  - high dose or rapid withdrawal symptoms: hyperpyrexia, seizures, death
  - onset: 1-2 d (short-acting), 2-4 d (long-acting)
  - duration: days-weeks
  - complication with above 50 mg diazepam/d or abrupt withdrawal: autonomic hyperactivity, seizures, delirium, arrhythmias
  - management: taper slowly, may need to switch to a long-acting benzodiazepine
  - similar to but less severe than alcohol withdrawal; can be fatal
- **overdose**
  - overdose is common but rarely fatal unless combined with other substances
  - more dangerous or potentially fatal when combined with alcohol, other CNS depressants, opioids, or TCAs

Benzodiazepines That are Safe for Patients with Impaired Liver Function

LOT
Lorazepam
Oxazepam
Temazepam

Buspirone (Buspar®)

- primary use: GAD
- may be preferred over benzodiazepines because it is non-sedating, has no interaction with alcohol, does not alter seizure threshold, not prone to abuse
- onset of action: 2 wk
- side effects: dizziness, drowsiness, nausea, headache, nervousness, EPS

Z-drugs for Sleep

- non-benzodiazepine sedatives indicated for short-term management of insomnia
- examples include zopiclone (Imovane®), eszopiclone (Lunesta®), and zolpidem (Sublinox®)
- anecdotally provide a more restful sleep than benzodiazepines
- similar side effect profile and warnings to benzodiazepines
- should not be used long-term due to side effects and likelihood of dependency

Table 22. Dosing and Indications for Common Anxiolytics

Class	Drug	Dose Range (mg/d)	$t_{1/2}$ (h)	tmax (h)	Appropriate Use
Benzodiazepines					
Long-acting	Clonazepam (Rivotril®)	0.25-4	18-50	1-4	Seizure prevention, akathisia, generalized anxiety disorder, panic disorder
	Diazepam (Valium®)	2-40	30-100	1-2	Seizure prevention, muscle relaxant, alcohol withdrawal, generalized anxiety
	Chlordiazepoxide (Librium®)	5-300	30-100	1-4	Alcohol withdrawal
	Flurazepam (Dalmane®)	15-30	50-160	0.5-1	Should be avoided
Short-acting	Alprazolam (Xanax®)	0.25-4.0	6-20	1-2	Should be avoided due to high dependency rate
	Lorazepam (Ativan®)	0.5-6.0	10-20	1-4	Alcohol withdrawal (no first-pass liver metabolism), akathisia, short-term sedation for anxiety during procedures (e.g. CT or MRI), generalized anxiety; sublingual or IM for rapid action
	Oxazepam (Serax®)	10-120	8-12	2-3	Alcohol withdrawal (no first-pass liver metabolism), generalized anxiety disorder
	Temazepam (Restoril®)	7.5-30	8-20	2-5	Should be avoided
	Triazolam (Halcion®)	0.125-0.5	1.5-5	1-2	Shortest $t_{1/2}$, rapid sleep without daytime sedation (e.g. overnight plane travel), but risk of rebound insomnia
Azapirones					
	Buspirone (Buspar®)	15-30	2-3	1-1.5	Generalized anxiety disorder

Somatic Therapies

Electroconvulsive Therapy

- ECT is a safe and controlled way of producing seizures to treat mental illness
- various methodological improvements have been made since the first treatment in 1938 to reduce adverse effects
- modern ECT: induction of a generalized seizure using an electrical pulse through scalp electrodes while the patient is under general anesthesia with a muscle relaxant
- considerations: unilateral vs. bilateral electrode placement, pulse rate, energy, number, and spacing of treatments
- usual course is 6-12 treatments, 2-3 treatments per wk
- indications
  - treatment-resistant depression (unipolar, bipolar I, bipolar II): psychotic features, catatonic features, when medications may be unsafe or rapid response is needed (e.g. cachexia, severe dehydration, frail elderly, high suicide risk, pregnancy)

ECT in Society
Prior to the 1940's, ECT was performed without the use of muscle relaxants, resulting in seizures with full-scale convulsions and rare but serious complications such as vertebral and long-bone fractures. This practice may have led to negative societal perceptions of ECT, further perpetuated by negative depictions in popular culture. Despite ongoing stigmatization, ECT as it is practiced today is an effective and safe option for patients with severe mental illness, including depression

  - catatonia: refractory, severe, or life-threatening
  - schizophrenia: treatment-resistant, acute symptoms, catatonia, history of NMS
  - mania: refractory, severe or life-threatening situation
  - personal or family history of good response to ECT
  - inconclusive evidence for OCD
- adverse effects: risk of anesthesia (equal to risk of ECT), memory loss (may be retrograde and/or anterograde, tends to resolve by 6-9 mo, permanent impairment controversial), transient headaches, transient myalgias
- unilateral ECT causes less memory loss than bilateral but may not be as effective
- contraindications: no absolute contraindications; relative contraindications: increased intracranial pressure, recent (<4 wk) hemorrhagic stroke, recent (<2 wk) MI, requires special monitoring

Electroconvulsive Therapy for Treatment Resistant Schizophrenia
Cochrane DB Syst Rev 2019;CD011847
Purpose: Assess benefits and harms of ECT for people with treatment-resistant schizophrenia.
Outcomes: Moderate-quality evidence indicates that relative to standard care, ECT has a positive effect on medium-term clinical response for people with treatment-resistant schizophrenia. However, there is no clear and convincing advantage or disadvantage for adding ECT to standard care for other outcomes.

Repetitive Transcranial Magnetic Stimulation (rTMS)

- noninvasive production of focal electrical currents in select brain circuits using magnetic induction
- indications: strong evidence for treatment-resistant depression and pain disorders; possibly efficacious for anxiety disorders, PTSD, eating disorders, and substance use disorders
- adverse effects: common – transient local discomfort, hearing issues, or cognitive changes; rare - seizure, syncope, mania induction

Magnetic Seizure Therapy (Experimental)

- magnetic seizure therapy (MST) is generalized seizure induction using strong magnetic current
- early studies demonstrate efficacy for depression as well as anxiety, with reduced memory effects vs. ECT

Neurosurgical Treatments

Ablative/Lesion Procedures

- used for MDD or OCD unresponsive to all other forms of treatment; efficacy ranges from 25-75% depending on procedure
- adverse effects: related to lesion location and size, high-risk of suicide in those who are not helped by surgery
- focused ultrasound therapy (FUS) is an experimental surgical technique under investigation for the treatment of MDD, OCD with the advantage of avoiding an open skull surgery

Deep Brain Stimulation (Experimental)

- placement of small electrode leads in specific brain areas to alter neuronal signaling
- most evidence for treating OCD, some evidence for other disorders such as treatment-resistant MDD
- response rates (>50% symptom reduction) of 40-70%, adverse effects related to surgical risks and poor treatment response

Vagus Nerve Stimulation

- direct, intermittent electrical stimulation of left cervical vagus nerve via implanted pulse generator
- used for chronic, recurrent MDD with poor response to previous therapy and ECT
- slow onset, approximately 30% response rate at 1 yr

Other Therapy Modalities

Phototherapy (Light Box Therapy)

- bright light source exposure (usually 10000 lux) for 30 min daily within the first hour of awakening
- proposed mechanisms: reverses pathological alterations in circadian rhythm through action on suprachiasmatic nucleus
- indications: seasonal affective disorder (SAD), non-seasonal depression (as augmentation), and some sleep disorders
- adverse effects: mania induction, reaction with photosensitizing drug or photosensitive eye or skin conditions

Aerobic Exercise

- moderate-intense aerobic exercise is associated with acute increased release of serotonin, phenethylamine, brain-derived neurotrophic factor, endogenous opioids, and cannabinoids (likely this combination is what contributes to the "runner's high")
- associated with long term increases grey matter in multiple areas, as well as improvements in cognition, memory, and stress tolerance
- indications: monotherapy for mild-moderate MDD; adjunctive therapy for moderate-severe MDD
- may be helpful in PTSD, schizophrenia

Canadian Legal Issues

Common Forms

- the legislation is specific to each province, as are the types and numbers of forms, but the principles are common across Canada

Table 23. Common Forms Under the Mental Health Act (in Ontario)

Form	Who Signs	When	Expiration Date	Right of Patient to Review Board Hearing	Options Before Form Expires
Form 1: Application by physician to bring a patient to hospital (schedule 1 facility) for psychiatric assessment against patient's will (Form 42 given to patient)	Any physician	Within 7 d after having examined the patient	72 h after hospitalization Void if not implemented within 7 d	No	Form 3 and 30 or voluntary admission or send home ± follow-up
Form 2: Order by Justice of the Peace to bring patient to a hospital for an examination against patient's will	Justice of the Peace	No statutory time restriction	7 d from when completed Purpose of form is complete once patient brought to hospital	No	Form 1 and 42 or voluntary admission or send home ± follow-up
Form 3: Certificate of involuntary admission to a schedule 1 facility (Form 30 given to patient, notice to rights advisor)	Any physician other than physician who completed Form 1	Before expiration of Form 1 Any time to change status of a voluntary inpatient	14 d	Yes	Form 4 and 30 or voluntary admission (Form 5)
Form 4: Certificate of renewal of involuntary admission to a schedule 1 facility (Form 30 given to patient, notice to rights advisor)	Any physician, usually the attending physician following patient on Form 3	Prior to expiration of Form 3	First: 1 mo Second: 2 mo Third: 3 mo (max)	Yes	Form 4 and 30 or voluntary admission (Form 5)
Form 4a: Certificate of continuation of involuntary admission to a schedule 1 facility (Form 30 given to patient, notice to rights advisor, Form 17 sent to the Capacity and Consent Board, copies to chart)	Any physician, usually the attending physician following patient on Form 4	Prior to expiration of the third Form 4	3 mo	Mandatory review board hearing	Another Form 4a or voluntary admission
Form 5: Change to informal/voluntary status	Any physician, usually the attending physician following patient on Form 3/4/4a	Whenever deemed appropriate (i.e. the criteria for involuntary admission under the Mental Health Act are no longer fulfilled)	N/A	N/A	N/A
Form 30: Notice to patient that patient is now under involuntary admission on either Form 3, 4, or 4a (original to patient, copy to chart)	Physician issuing the Form 3/4/4a	Whenever Form 3/4/4a filled	N/A	Yes	N/A
Form 33: Notice to patient that patient is incapable of consenting to treatment of a mental disorder, and/or management of property and/or disclosure of health information (original to patient, notice to rights advisor, copy to chart)	Attending physician	Whenever deemed appropriate	N/A	Yes	N/A
Form 42: Notice to the patient that patient is now on a From 1 and the reason for this change (original to patient, copy to chart)	Physician who is signing Form 1	Whenever Form 1 filled	N/A	No	

* Schedule 1 Facilities: Able to provide intensive inpatient and outpatient care

Form 1: Application for Psychiatric Assessment

- Filled out when patients are thought to be in imminent danger to harm themselves (suicide) or others (homicide) or when they are incapable of self-care (e.g. not dressed for freezing weather) and are suffering from an apparent mental disorder
- Based on any combination of the physician's own observations and facts communicated by others
- Box A or Box B completed
- **Box A:** Serious Harm Test
- The Past/Present Test assesses current behaviours/threats/attempts
- The Future Test assesses the likelihood of serious harm occurring as a result of the presenting mental disorder. In this section, one should document evidence of the mental disorder and concerning behaviour/thoughts
- **Box B:** Patients with a known mental disorder, who are incapable of consenting to treatment (substitute decision-maker needed), have previously received treatment and improved, and are currently at risk of serious harm due to the same mental disorder

Consent

- see Ethical, Legal, and Organizational Medicine, ELOM11

CTO Legislature

- Ontario passed CTO legislature on December 1, 2000 (known as "Brian's Law")
- Similar CTOs have been implemented in Saskatchewan (1995), Manitoba (1997), and British Columbia (1999)

Community Treatment Order (CTO)

- purpose: a community treatment order (CTO) orders a person suffering from a serious mental disorder to receive treatment and supervision in the community. Based on a comprehensive plan outlining medications, appointments, and other care believed necessary to allow the person to live in the community (vs. in a psychiatric facility, where conditions are more restrictive)
- intended for those who:
  - due to their serious mental disorder, experience a pattern of admission to a psychiatric facility where condition is usually stabilized
  - after being released, these patients often stop treatment, leading to destabilization
  - due to the destabilization of their condition, these patients usually require readmission to hospital
  - if CTO violated (i.e. treatment not taken), the physician can issue a Form 47 which is an order for examination that allows the police to bring the patient to the hospital for an examination (usually the patient is examined and the treatment will continue as per the CTO)
- criteria for a physician to issue a CTO
  - patient with a prior history of psychiatric hospitalization (cumulative ≥30 d over ≥2 hospitalizations in the past 3 yr), or the person has been subject to a previous CTO in the past 3 yr
  - a community treatment plan for the person has been made
  - examination by a physician within the previous 72 h before entering into the CTO plan
  - ability of the person subject to the CTO to comply with it
  - consultation with a rights advisor and consent of the person or the person's substitute decision maker
- CTOs are valid for 6 mo unless they are renewed or terminated at an earlier date such as
  - when the person or his/her substitute decision-maker withdraws consent to the community treatment plan
- CTO process is consent-based and all statutory protections governing informed consent apply
- the rights of a person subject to a CTO include
  - the right to a review by the Consent and Capacity Board with appeal to the courts each time a CTO is issued or renewed
  - a mandatory review by the Consent and Capacity Board every second time a CTO is renewed
  - the right to request a re-examination by the issuing physician to determine if the CTO is still necessary for the person to live in the community
  - the right to review findings of incapacity to consent to treatment
  - provisions for rights advice

CTO Legislature
- Ontario passed CTO legislature on December 1, 2000 (known as "Brian's Law")
- Similar CTOs have been implemented in Saskatchewan (1995), Manitoba (1997), and British Columbia (1999)

Duty to Inform/Warn

- see Ethical, Legal, and Organizational Medicine, ELOM10

Landmark Psychiatry Clinical Trials

Trial	Reference	Results
Schizophrenia		
CATIE	Psychiatr Serv 2008;59(5):500-506	**Title**: What CATIE Found: Results From the Schizophrenia Trial **Purpose**: Compare the effectiveness of a proxy first-generation antipsychotic (perphenazine) to several second-generation antipsychotics. **Methods**: 1460 patients with chronic schizophrenia were randomly assigned in a double-blind study to receive one of perphenazine, olanzapine, quetiapine, risperidone, or ziprasidone for up to 18 mo. **Results**: Perphenazine did not differ significantly in overall effectiveness or benefits compared to the second-generation antipsychotics. Perphenazine was the most cost-effective drug. Individual clinical circumstances impacted drug effectiveness. Patients who have a poor response to an initial medication may tolerate and see greater effectiveness with a different medication. **Conclusions**: First and second-generation antipsychotics did not differ in overall effectiveness. Patient factors must be considered when prescribing antipsychotic medications.
Major Depressive Disorder		
TRANSFORM-2	Am J Psychiatry 2019,176(6):428-438	**Title**: Efficacy and Safety of Flexibly Dosed Esketamine Nasal Spray Combined With a Newly Initiated Oral Antidepressant in Treatment-Resistant Depression: A Randomized Double-Blind Active-Controlled Study **Purpose**: Evaluate the efficacy and safety of flexibly dosed esketamine nasal spray for patients with treatment-resistant depression. **Methods**: Patients with treatment-resistant depression were randomly assigned treatment of esketamine nasal spray with a newly initiated antidepressant or a placebo nasal spray with a newly initiated antidepressant. **Results**: 197 participants completed the study. Patients receiving the esketamine nasal spray plus antidepressant treatment demonstrated a change in Montgomery-Åsberg Depression Rating Scale score that was significantly greater than placebo nasal spray plus antidepressant at day 28. Clinically meaningful improvements were found in the esketamine group earlier in the study timeline. **Conclusions**: Esketamine nasal spray was a safe, rapid-acting, and efficacious therapy for treatment-resistant depression.

Public Health Context

- see Ethical, Legal, and Organizational Medicine, *Overview of Canadian Healthcare System*, ELOM2 for the organization of health care in Canada including the legal foundation and historical context

Definitions

- **population health**
  - refers to the health of defined groups of people, their health determinants, trends in health, and health inequalities
  - influenced by: physical, biological, social, environmental, and economic factors; personal health behaviours; health care services
  - broader scope compared to public health; accounts for socioeconomic, policy, and historical issues
- **public health**
  - an organized effort by society to promote, protect, improve, and when necessary, restore the health of individuals, specified groups, or the entire population
  - a combination of sciences, skills, and values that function through collective societal activities and involve programs, services, and institutions aimed at protecting and improving the health of all people
  - public health services in many provinces (e.g. Ontario) are administered, funded, and delivered entirely separately from healthcare services
- **epidemiology**
  - "study of the distribution […] of determinants of disease, health-related states, and events in populations"
- **public health and preventive medicine** (formerly called community medicine)
  - the medical specialty that focuses on population rather than individuals' health
  - works with diverse populations to improve population health, address social determinants of health, and promote health equity
  - 5 yr Royal College training in medical skills and knowledge, epidemiology, statistics, social sciences, public administration, policy development, program management, and leadership

Sources: Shah, CP. Chapter 2 Measurement and Investigation. Public Health and Preventive Medicine in Canada, 5e. Toronto: Elsevier, 2003
Shah, CP. Chapter 15 Community Health Services. Public Health and Preventive Medicine in Canada, 5e. Toronto: Elsevier, 2003

Public Health in Canada

The Public Health System in Canada is composed of various agencies at the federal (Public Health Agency of Canada), provincial (Public Health Ontario), and municipal/local levels (local public health units). The organization of the public health system in each province varies widely and is usually separate from the health care system.

Mission of the Public Health Agency of Canada (federal only): to promote and protect the health of Canadians through leadership, partnership, innovation, preparedness, and action in public health

- local public health units and services within regional health authorities (in most provinces except Ontario, where local public health units are either autonomous or within local government) provide programs and activities for health protection, promotion, and disease prevention at local and regional levels
- catchment-area populations range widely (100s to 1000000s), covering areas of 15 km^2 to 1.5 million km^2
- the "core functions" of public health include six essential activities

(The Organization of Health Services in Canada. AFMC Primer on Population Health, Accessed: March 25 2016)

1. health protection: measures taken to address potential risks to health at the population level through regulation and advising government (e.g. safe water and food supply)
2. health surveillance: monitoring and predicting health outcomes and determinants with systematic, longitudinal data collection
3. disease and injury prevention: address infectious disease through preventive (e.g. vaccination, droplet protection) and control (e.g. quarantine) measures; reduce morbidity through lifestyle improvement

Preparing for the LMCC
The AFMC Primer on Population Health is the core text for the LMCC and is available as an online resource on the AFMC website (http://phprimer.afmc.ca) For the LMCC exam, it is recommended that you also read Chapter 15 in Shah CP. Public health and preventive medicine in Canada, 5th ed. Toronto: Elsevier, 2003

Historical Perspective
Over the last century, the focus of public health has evolved:

- **Infectious diseases:** a prominent issue in low- and middle-income countries and higher income countries alike; includes emergent diseases caused by unfamiliar or new pathogens, inefficient or inappropriate antibiotic use, travel, global warming (e.g. HIV, drug-resistant TB, COVID-19), and the manufactured conditions of crisis and/or routine conditions of poverty imposed on Indigenous, Black, and other communities of colour
- **Chronic diseases:** have increased morbidity and mortality (e.g. heart disease and cancer due to risk factors and/or exposures) and disproportionately affect Indigenous populations throughout the world
- **Social determinants of health:** driven by a growing body of evidence since the 1980s that universal access to health care services did not ameliorate health inequalities, and that significant improvements in health could only be achieved by going 'upstream' with action on policies

Example of a Municipal Health Unit: The Middlesex-London Health Unit

- Serves 450000 people living, working, visiting, and studying in the city of London and Middlesex county
- 275 full-time staff including MOHs (physicians), public health nurses, epidemiologists, health promotion educators, dental hygiene managers, etc.
- Services include infectious disease control, ensuring environmental health standards, health promotion, and providing family health programs

4. population health assessment: studying and engaging with a community to understand their needs and improve policies and services
5. health promotion: advocate for improved health through broad community and government measures (e.g. policy, interventions, community organizations)
6. emergency preparedness and response: developing protocols and infrastructure for natural (e.g. hurricane) and man-made (e.g. opioid crisis) disasters. In many types of health-related disasters, public health leads the disaster response

Sources: Shah, CP. Chapter 15 Community Health Services. Public Health and Preventive Medicine in Canada, 5e. Toronto: Elsevier, 2003
The Association of Faculties of Medicine of Canada Public Health Educators' Network. The Organization of Health Services in Canada. AFMC Primer on Population Health

Legislation and Public Health in Canada

Table 1. Legislation and Public Health in Canada

Federal	Provincial	Municipal (Ontario)
Health Canada • Provides health services to the Canadian military and veterans • Provides non-insured health benefits (NIHB) to status First Nations peoples and Inuit, and is responsible for the funding of healthcare services on reserve • Approves new drugs and medical devices • Food Guide **Public Health Agency of Canada** (main Government of Canada agency responsible for public health) • An independent body created post-SARS to strengthen public health capacity and response • Focuses on preventing chronic diseases, preventing injuries, and responding to public health emergencies and infectious disease outbreaks • Activities include CTFPHC guideline secretariat, knowledge brokers • Oversees immigration screening, protects Canadian borders (e.g. airport health inspection) • Liaises with the WHO on global health issues **Canadian Food Inspection Agency** • Regulates food labeling • Deals with animal-related infections **Canadian Institutes of Health Research (CIHR)** • Formed in 2000 to support research to improve health and the health care system	Each province has its own Public Health Act or equivalent (e.g. the *Health Protection and Promotion Act* in Ontario) and agencies (e.g. Public Health Ontario) • Designates the creation of geographic areas for the provision of public health services • Gives powers to the Chief Medical Officer of Health to control public health hazards • Specifies diseases to be reported to public health units by physicians, laboratories, and hospitals (see *Appendix*, PH32) • Mandates programs that address public health issues, environmental health, and chronic disease prevention	Local public health units (e.g. Middlesex-London Health Unit) deliver programs mandated by provincial, municipal, or regional legislation and are responsible for the delivery of most public health services, such as: • Infectious disease control, including the follow-up of reported diseases and management of local outbreaks • Inspection of food premises including those in hospitals, nursing homes, and restaurants • Family health services including pre-conception, preschool, school-aged, and adult health programs • Tobacco control legislation enforcement • Assessment and management of local environmental health risks • Collection and dissemination of local health status reports • Oral health • By-laws may be approved by municipal governments to facilitate public health issues

Chief Public Health Officer (CPHO) of Canada
- Responsible for the Public Health Agency of Canada (PHAC) and reports to the Minister of Health
- As the federal government's lead public health professional, provides advice to the Minister of Health and Government of Canada and collaborates with other governments, jurisdictions, agencies, organizations, and countries on health matters
- Communicates public health information to health professionals, stakeholders, and the public
- In an emergency, such as an outbreak or natural disaster, directs PHAC staff, including medical professionals, scientists, and epidemiologists, to coordinate emergency response

Source: Public Health Agency of Canada. www.canada.ca/en/public-health/corporate/organizational-structure/canada-chief-public-health-officer/role-chief-public-health-officer.html

Medical Officer of Health (MOH) (Ontario)
- May be called "Medical Health Officer" (MHO) in other provinces
- Appointed to each public health unit by the board of health
- Position held by a Public Health and Preventive Medicine specialist physician
- Responsibilities include oversight of a multidisciplinary team who:
  - Collect and analyze epidemiological data
  - Provide occupational and environmental health surveillance
  - Implement health programs, including tobacco use prevention inspections (restaurants, physician's offices, tattoo parlors) and prenatal courses
  - The MOH, by law, can require an individual/premise/agency to take or refrain from any action due to a public health hazard (Section 13 and 22 of the Health Protection and Promotion Act)

Determinants of Health

Concepts of Health

- **wellness**: "state of dynamic physical, mental, social, and spiritual well-being that enables a person to achieve full potential and have an enjoyable life"
- **disease**: "abnormal, medically-defined changes in the structure or function of the human body"
- **illness**: "an individual's experience or subjective perception of a lack of physical or mental well-being and consequent inability to function normally in social roles"
- **illness behaviour**: an individual's actions resulting from and responding to their illness, including their interactions with, or avoidance of, the healthcare system
- **sickness**: views the individual and their society hold towards a health condition, affecting their thoughts and actions
- **impairment**: "any loss or abnormality of psychological, physiological, or anatomical structure or function"
- **disability**: "any restriction or lack of ability to perform an activity within the range considered normal for a human being"
- **handicap**: a disadvantage for an individual arising from impairment or disability
  - "limits or prevents the fulfillment of an individual's normal role as determined by society and depends on age, sex, social, and cultural factors"

Determinants of Health
- Income and social status
- Employment and working conditions
- Education and literacy
- Childhood experiences
- Physical environments
- Social supports and coping skills
- Healthy behaviours
- Access to health services
- Biology and genetic endowment
- Gender
- Culture
- Exposure to colonization and racialized prejudice
- Racism

Source: Public Health Agency of Canada. https://www.canada.ca/en/public-health/services/health-promotion/population-health/what-determines-health.html

- **health equity**: when all people have "the opportunity to attain their full health potential" and no one is "disadvantaged from achieving this potential because of their social position or other socially determined circumstance." Health inequities are systematic differences in the health of individuals/groups which are considered unjust
- **health equality**: defined as where populations have equal or similar health status. Health inequalities are systematic differences in the health of groups that do not necessarily carry a moral judgement

Source: ACC Institute of Human Services, Special Needs Education. Impairment, Disability, and Handicap: What's the Difference? [Internet]. Institute of Human Services; 2018 Nov 9 [cited 2020 Apr 28]. Available from: https://acc.edu.sg/en/impairment-disability-and-handicap-whats-the-difference/

Determinants of Health

- 1974: the Honourable Marc Lalonde, federal Minister of Health, publishes A New Perspective on the Health of Canadians which outlines four factors that determine health: "human biology, environment, lifestyle, and health care organizations." The idea of determinants of health has since been expanded and refined to include many additional factors

Sources: Shah, CP. Concepts, Determinants, and Promotion of Health. Public Health and Preventive Medicine in Canada, 5e. Toronto: Elsevier, 2003
The Association of Faculties of Medicine of Canada Public Health Educators' Network. Concepts of Health and Illness. AFMC Primer on Population Health

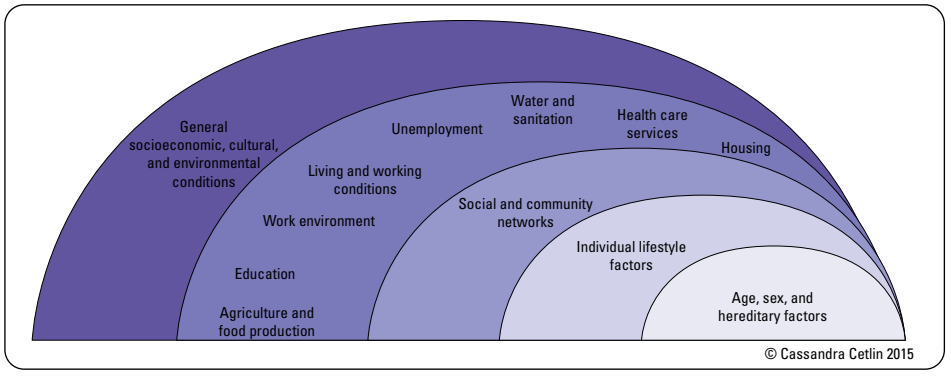

Figure 1. Population health model
Adapted from Dahlgreen G, Whitehead M. European strategies for tackling social inequities in health: Leveling up Part 2. World Health Organization, 2006

- **cultural humility**: an approach to health care based on humble acknowledgement of oneself as a learner when it comes to understanding a person's experience. This is a life-long process of learning and being self-reflexive
- **cultural safety**:
  - developed by Dr. Irihapeti Ramsden, a Maori nurse scientist, in the 1980s and is "concerned with the power relationships between nurses and those in their care. The recipients of nursing care are empowered to decide what is culturally safe rather than complying passively with the authority of nurses or other health professionals" - Cancer Australia
  - "an approach that considers how social and historical contexts, as well as structural and interpersonal power imbalances, shape health and health care experiences. Practitioners are self-reflective/self-aware with regards to their position of power and the impact of this role in relation to patients" - HeretoHelp British Columbia
- **cultural awareness**: an attitude that includes awareness about differences between cultures
- **cultural sensitivity**: an attitude that recognizes the differences between cultures and that these differences are important to acknowledge in health care
- **cultural competency**: an approach that focuses on practitioners' attaining skills, knowledge, and attitudes to work in more effective and respectful ways with Indigenous patients and people of different cultures

Groups Facing Systemic Barriers, Discrimination, and Structural Violence

- certain groups are at greater risk for poorer health outcomes not due to their identity, but rather due to systemic barriers, discrimination, and structural violence (e.g. harmful policies, historic, and contemporary factors). The readers are strongly cautioned against pathologizing entire groups and are encouraged to further read into the historical factors that have contributed to creating systemic barriers which perpetuate inequities
- see *Colonization and Healthcare*, PH7; Ethical, Legal, and Organizational Medicine, *Indigenous Disproportionate Over-Representation of Biological, Psychological and Social Co-Morbidities*, ELOM27; *Indigenous Health*, ELOM24

Definitions of Health

- Multidimensional definition of health, as defined by the WHO in 1948: "state of complete physical, mental and social well-being and not merely the absence of disease or infirmity"
- WHO updated the definition (socio-ecological definition) of health in 1986: "The ability to identify and to realize aspirations, to satisfy needs, and to change or cope with the environment. Health is therefore a resource for everyday life, not the objective of living. Health is a positive concept emphasizing social and personal resources, as well as physical capacities" (Ottawa Charter for Health Promotion)
- Other definitions of health have since been proposed that incorporate other dimensions of health
- "Health is a social, economic, and political issue and above all a fundamental human right" – The People's Charter for Health
- "Health is the continuous and harmonious interaction and balance between the physical, emotional, spiritual, and mental/intellectual realms" - The National Aboriginal Health Organization

State of the Art Review: Poverty and the Developing Brain

Pediatrics 2016;13(4):e20153075
Socioeconomic status (SES) plays an important role in paediatric brain development. Lower SES is associated with developmental delay, lower academic achievement, and more behavioural and emotional problems. SES has been found to influence brain regions that support memory, emotion regulation, higher-order cognitive functioning, and regions that support language and literacy. Some possible mechanisms underlying these changes include epigenetics, material deprivation (e.g. cognitive stimulation, nutrient deficiencies), stress (e.g. negative parenting behaviours), and environmental toxins. There is a need for primary care providers to build capacity to address poverty in their practice and facilitate referral to evidence based community intervention programs.

Ottawa Charter for Health Promotion (1986)

- Health promotion: the process of enabling people to increase control over, and improve their health
- Some health promotion can be achieved through clinical interactions with patients, but most health promotion is done at the population level by public health professionals and agencies through engaging stakeholders, formulating policy, and influencing upstream factors
- The Ottawa Charter is a framework for thinking about health promotion
- The Ottawa Charter states that governments and health care providers should be involved in a health promotion process that includes:
  1. Building healthy public policy
  2. Creating supportive environments
  3. Strengthening community action
  4. Developing personal skills
  5. Re-orienting health services

Table 2. Equity-Seeking Groups Facing Systemic Barriers

	Definition	Physical	Environmental	Personal Risk Factors	Population-Specific Interventions
Indigenous Peoples	Three distinct groups: First Nations (status and non-status Indians as per the Indian Act), Métis, and Inuit The original inhabitants of the land now called Canada All Indigenous communities and individuals experience the effects of colonization, but sometimes in very different ways	A history of surviving colonization and genocide Systemic racism Lower income Higher risk of experiencing violence and unemployment Homelessness	Limited overcrowded housing in disrepair in community Homelessness off-reserve Exposures to environmental toxins (poor drinking water) due to land dispossession and loss of environmental stewardship	Lifestyle adaptation, loss of traditional livelihood, unemployment, and lack of facilities Obesity (higher BMI) secondary to poorer access to high quality nutrition (food insecurity) Higher rates of smoking, substance misuse, and suicide secondary to intergenerational trauma	Movements towards decolonization and addressing the recommendations of the Truth and Reconciliation Commission Mental health awareness and increasing health literacy Indigenous-specific chronic disease management including DM Culturally appropriate and interdisciplinary harm reduction, substance use treatment, and smoking cessation programs Cultural continuity (language and cultural programs are protective against depression and suicide) Incorporation of Traditional Medicine into the care plan (wellness journey) for Indigenous patients who want this to be part of their care Health practitioner training in cultural humility and safety
Black Individuals and Communities	Sub-Saharan African Ancestry, diverse cultures and histories (people may self-identify by geographic or ancestral regions (e.g. Caribbean, Ghanaian, Somali, African American, Black Canadian, etc.) but socially classified by society based on hair/skin phenotype as 'Black') 3rd largest "visible minority" group in Canada 43% Canadian-born	Variable, depending on socioeconomic status and immigrant status/history in Canada The Nova Scotian Black population has been in Canada for centuries; historically displaced into rural settings Newer immigrants tend to live in urban centres	Anti-Black systemic racism in Canada (officially acknowledged by the United Nations, the Canadian Public Health Association, and several provincial and local governments) has led to physical and mental health inequities High BMI Higher risk DM and HTN (poor data quality for identifying disparities in Canada due to lack of collection of race-based data)	Anti-Black systemic racism in Canada (officially acknowledged by the United Nations, the Canadian Public Health Association, and several provincial and local governments) has led to physical and mental health inequities High BMI Higher risk DM and HTN (poor data quality for identifying disparities in Canada due to lack of collection of race-based data)	Culturally-specific and safe practices Anti-racist approaches to care, policy, and programming Movements to reallocate police funding to more appropriate social services to curb police violence through transparency and public oversight
Isolated Seniors	Individuals >65 yr	Elder abuse Lack of emotional support Isolation	Low hazard tolerance Higher rates of institutionalization Mobility issues	Inactivity Polypharmacy Medical comorbidities	Aging in place of choice Falls and injury prevention Mental health promotion Preventing abuse and neglect
Individuals/Children in Poverty	Based on LICOs LICO is an income threshold below which a family will likely devote a larger share of its income on the necessities of food, shelter, and clothing than the average family	Low income Family dysfunction Lack of educational opportunities	Housing availability Unsafe housing Lack of recreational space	Poor supervision Food insecurity High-risk behaviours	Improvements in family income most significant Access to early childhood education Access to safe housing
People with Disabilities	Includes impairments, activity limitations, and participation restrictions	Low income Low education status Discrimination Stigma	Institutionalization Barriers to access Transportation challenges	Substance misuse Poor nutrition Inactivity Dependency for ADLs	Transportation support Multidisciplinary care Unique support for individuals with specific disabilities (e.g. Trisomy 21)
New Immigrants	Person born outside of Canada who has been granted the right to live in Canada permanently by immigration authorities	Access to community services Cultural perspectives (including reliance on alternative health practices) Unstable or precarious housing	Exposure to diseases and conditions in country of origin, in current country of residence, or during immigration process (e.g. smoke from wood fires, incidence of TB)	Barriers finding employment that matches skills and qualifications Exposure to cultural discrimination and isolation which can impact health English language learner Healthy immigrant effect (health worsens over time to match that of the general population) Cultural or religious expectations	Women's health Mental health Comprehensive medical exam Dental and vision screening Vaccinations Cancer screening Receive language and employment training Support integrating into local community Benefit from culturally appropriate and culturally safe interventions, ideally developed in collaboration with the specific target communities

Note: this chart delineates the major challenges faced by each group, but the issues listed are not unique to each population.
Sources: Shah, CP. The Health of Vulnerable Groups. Public Health and Preventive Medicine in Canada, 5e. Toronto: Elsevier, 2003.

Table 2. Equity-Seeking Groups Facing Systemic Barriers

	Definition	Physical	Environmental	Personal Risk Factors	Population-Specific Interventions
Persons with no Fixed Address	An individual who lacks permanent housing	Low income Food insecurity Mental illness	A history of colonial subjugation and land expropriation Exposure to temperature extremes Exposure to communicable diseases in shelters	Higher rates of adverse childhood events and subsequent substance use Greater risk of experiencing violence due to lack of housing and protection	Housing First policies Safe housing Addictions support Mental health
Refugees	Forced to flee country of origin because of a well-founded fear of persecution and given protection by the Government of Canada Refugee claimant: arrive in Canada and ask to be considered refugee	Post-traumatic stress disorders Depression Adjustment problems Partial health coverage via Interim Federal Health Program	Diseases and conditions in country of origin (e.g. malaria, TB, onchocerciasis, etc.) Direct and indirect effects of war	Employment English language learner Longstanding prior lack of access to health care (chronically neglected problems) Cultural or religious expectations	Vaccinations Women's health Mental health Comprehensive medical exam Dental and vision screening Political advocacy Language training Support for transitioning into the workplace Support integrating into local community
Religious Minorities	Religious minorities are those who do not practice the statistically dominant faith It varies by country, but in Canada, religious minorities are currently those who are not affiliated with one of the major Christian denominations Not all members of a minority faith practice and degree of identification varies by individual	Reduced employment options in Quebec due to laws banning government workers such as teachers, police officers, publicly employed lawyers, and court workers from wearing religious symbols like hijabs, turbans, and kippahs	At risk of experiencing hate crimes, especially those who wear visible religious symbols such as Muslim women, Sikh men, and Jewish men	Poorer mental health Suboptimal health and care-seeking behaviours	If possible and when requested, offer patients a healthcare provider of the same gender Provide accessible multi-faith spaces and chaplain services in the hospital Instill a culture of inclusion beyond tolerance and provide religious accommodation where possible Proactively consult healthcare workers if they require alternative scheduling for religious holidays or fasting Collaborate with religious leaders and chaplains in supporting the health of their respective communities
LGBTIQ2S Individuals	Those who identify as lesbian (a homosexual woman), gay (a homosexual person irrespective of gender), bisexual (a person who is attracted to both genders), trans (a person whose core gender identity and/or gender expression does not align with the sex-assigned gender at birth; the sexuality of trans persons is independent of their gender diversity), intersex (an umbrella term to describe bodies that fall outside the strict male/female binary), questioning (regarding one's sexual or gender identity), queer (a historically reclaimed pejorative that is an umbrella term to encompass all sexual and gender diversities), two-spirited (a pan-indigenous term acknowledging gender diversity in uniquely traditional roles as distinct from western gender diverse identities), and asexual (a person who does not experience sexual attraction to others as distinct from celibacy; asexual individuals may still have sex	Family violence Lower income Identity documents lacking correct name or sex designations Victims of hate crimes motivated by sexual orientation and/or gender identity; higher prevalence of hate crimes against racialized communities with greater fatality	Over-representation in youth homeless population Violence, harassment, and discrimination when seeking stable housing, employment, health, or social services	Higher rates of depression, anxiety, obsessive-compulsive and phobic disorders, suicidality, and self-harm Increased risk of alcohol, tobacco, and other substance misuse Double the risk for post-traumatic stress disorder than heterosexual people Greater participation in high-risk sexual practices related to HIV infection Deterioration of mental health due to multiple factors (internalized queerphobia, limited sociomedical infrastructure perpetuating/instigating underlying comorbidities)	Apply an intersectional lens to understand LGBTIQ2S populations (racialized, gender-diverse, traditional/cultural roles as in 2S) Gender-neutral language and the avoidance of heteronormative assumptions to invite patients to self-identify as gender or sexual minorities Increased awareness of the broader social, legal, and medical context in which LGBTIQ2S individuals live Improve recognition that individuals who belong to multiple marginalized communities may face additional barriers to maintaining good health

Note: this chart delineates the major challenges faced by each group, but the issues listed are not unique to each population.
Sources: Shah, CP. The Health of Vulnerable Groups. Public Health and Preventive Medicine in Canada, 5e. Toronto: Elsevier, 2003.

Screening for Poverty
- poverty is not always apparent despite being widespread (20% of families in Ontario live in poverty)
- poverty is a risk factor for many chronic diseases, cancer, and mental illness
- women, Indigenous peoples, new immigrants, and LGBTQ+ are some of the groups at highest risk of living in poverty
- primary healthcare providers should intervene
  - step 1: screen everyone for poverty by asking, "Do you ever have difficulty making ends meet at the end of the month?"
    - for living below the poverty line, sensitivity 98% and specificity 40%
  - step 2: ask everyone, "Have you filled out and sent in your tax forms?"
    - tax returns are required for accessing many income security benefits like GST/HST credit, working income tax benefits, property tax credits, child benefits, etc.
    - connect your patients to a free community tax clinic to assist them

Indigenous Health in Canada

Definitions
- Indigenous peoples represent approximately 4.9% of the total population of Canada in 2016 and speak over 70 Indigenous languages
- 3 distinct groups of Indigenous peoples in Canada (per sec. 35 of the *Constitution Act* 1982): First Nations (status and non-status), Métis, and Inuit
  - First Nations: includes over 600 diverse communities in Canada; status vs. non-status refers to the registration of First Nations peoples under the *Indian Act* (1876), which, in addition to the establishment of the Department of Indian Affairs, was originally established by the government to administer/manage Treaty commitments, and to remove self-governing and traditional practice rights. The *Indian Act* affectsIndigenous life in many areas from birth to death. It has impacted every First Nations individual, family and community
  - Métis: descendants of the First Nations and European settlers; nearly 2/3 residing in cities, greatest percentage in Ontario
  - Inuit: roughly 75% of this population of 70000 resides in the 4 Canadian Regions known as Inuit Nunangat, the Inuit Homeland. These include: Nunavut, Nunavik (N. Quebec), Nunatsiavut (Labrador), and Inuvialuit (Northwest Territories). The majority of Inuit live in Nunavut (30135), followed by Nunavik (11800), Inuvialuit (3110), and Nunatsiavut (2285). Another 17690 Inuit live outside of Inuit Nunangat, many in urban centres in southern Canada, including Ottawa, Edmonton, and Montréal

Young and Growing Populations
- between 2006-2016 the Indigenous populations have increased by 42.5%, 4x that of non-Indigenous Canadian population growth
- 32.1 is the average age of the Indigenous population, about 8 yr younger than the non-Indigenous Canadian population
- the aging Indigenous population is also growing, with anticipated doubling of >65 age group by 2036

Colonization and Healthcare
Colonizers have perpetrated specific acts throughout Canadian history that have greatly impacted the physical, mental, emotional, and spiritual health of Indigenous peoples. Physicians should therefore be aware of the historical (and current) underpinnings of Indigenous health disparities, and the way in which health care professionals, including physicians, have acted as agents of the colonial agenda historically, which are discussed here, and their responsibility to redress previously damaged healthcare relationships (see Ethical, Legal, and Organizational Medicine, *Resources in Indigenous Health*, ELOM29). Despite institutionalized abuse and assimilation, Indigenous people have survived remarkable injustice and have built resilience through traditional knowledge and practices

Residential Schools (1870s-1996)
The residential school era is well-known for its lasting and damaging effects on many generations of Indigenous people. Many Indigenous students suffered from poor nutrition, hygiene, and living conditions, as well as physical, sexual, and psychological abuse from teachers and others in power. The intent of residential schools to assimilate Indigenous people also led to spiritual harms through significant loss of traditional language and culture. Residential school survivors report poorer general and self-rated health as well as increased rates of chronic and infectious diseases, mental distress, depression, substance use, and suicide. Importantly, many of these outcomes extend to subsequent generations (i.e. intergenerational trauma)

The term "residential school syndrome" has been proposed to better characterize the traditional DSM-V definition of post-traumatic stress disorder with additional criteria specific to residential school survivors, such as tendency to misuse alcohol and drugs (often at a young age), loss of cultural knowledge, violent or angry outbursts, and difficulty parenting. Treatment approaches must take into account a holistic view of all these criteria, rather than simply focusing on one aspect, like substance use, which often perpetuates negative stereotypes

New Immigrants to Canada
- Mandatory medical exams on entry to Canada by a designated medical practitioner
- Complete medical examination for persons of all ages
- Chest x-ray and report for persons ≥11 yr
- Urinalysis for persons ≥5 yr
- Syphilis serology for persons ≥15 yr
- HIV testing for applicants ≥15 yr, as well as for those children who have received blood or blood products, have a known HIV-positive mother, or have an identified risk. An ELISA HIV screening test should be done for HIV 1 and HIV 2
- Serum creatinine for persons ≥15 yr, and children with a history of HTN (resting BP >150/90 mmHg), DM, kidney disease, or signs of impaired renal function
- Provide compassionate psychosocial assessment being aware of increased prevalence of mental health issues (e.g. PTSD, depression, intimate partner violence)
- Assess immunization documents and develop catch-up schedule

Traditional and Complementary Medicine Use Among Indigenous Cancer Patients in Australia, Canada, New Zealand, and the United States: A Systematic Review
Integr Cancer Ther 2018;17(3): 568-581
Purpose: To systematically review the use of traditional Indigenous and complementary medicines among Indigenous cancer patients in Australia, Canada, New Zealand, and the United States.
Methods: Studies on the use of traditional Indigenous and complementary medicines among Indigenous cancer patients in Australia, Canada, New Zealand, and the United States published between January 2000 and October 2017 were eligible for inclusion.
Results: 21 articles based on 18 studies were included. Traditional Indigenous and complementary medicines were used by between 19% to 57.7% of Indigenous patients. These modalities were most often used in combination with conventional cancer treatments to meet spiritual, emotional, and cultural needs. These treatments had multiple perceived spiritual, emotional, and cultural benefits. Traditional Indigenous and complementary medicine use was influenced by a patient's perceptions of their healthcare practitioner's attitudes towards these modalities.

In Canada, many Indigenous healing practices include drumming, singing, smudging, herbal teas, sweat lodges, and other ceremonies. Healthcare providers are encouraged to research and explore these options as an additional therapeutic tool for Indigenous patients requesting them. Not all Indigenous patients will request such treatments and so perhaps first ask patients, "What do I need to know about you as a person to give you the best care possible?"

The Truth and Reconciliation Commission (TRC) (2015) is a document jointly created by the Canadian government and residential school survivors that preserves in writing the truth of residential schools and delineates recommendations for reconciliation. Many TRC recommendations pertain directly to health and healthcare providers. Unfortunately, seven years later they remain recommendations and have not become Calls to Action

Nutrition Trials

From 1942 to 1952, nutritional scientists in conjunction with the Canadian government performed unethical research on Indigenous people with the aim of "studying the state of nutrition of the Indian." The James Bay Survey is perhaps the most well-known of these studies conducted on the Attawapiskat and Rupert's House Cree First Nations, though many were conducted on residential school children as well. One of the lead physician-scientists was Dr. Frederick Tisdall (inventor of Pablum), former president of the Canadian Paediatric Society and paediatrician at the Hospital for Sick Children in Toronto, Ontario. Some unethical and arguably criminal acts committed by researchers were:

- lack of informed consent from parents or children
- Indigenous children were kept malnourished over a two-year period to establish a baseline
- one group of children received a flour mix not yet approved for sale that caused them to develop anemia, contributing to greater morbidity and mortality in this group with no therapeutic intervention
- in an effort to control as many factors as possible, dental care was denied to observe the progression of dental cavities and gingivitis in the setting of malnutrition

Impact of Sustained Caloric Restriction on Residential School Survivors and Other Generations

- sustained caloric restriction can cause height stunting, induce physiological changes to prioritize fat over lean mass, and higher risk of developing type 2 diabetes
- stunting negatively impacts neurological, psychological and immune systems
- due to sustained starvation, "the child's physiology is essentially 'programmed' by hunger to continue the cycle of worsening effects, with their bodies displaying a rapid tendency for fat-mass accumulation when nutritional resources become available"
- other generations are at risk of having a higher BMI and developing obesity

Tuberculosis, Tuberculosis Sanatoriums, and "Indian Hospitals"

European colonizers brought tuberculosis (TB) to Indigenous populations as early as the 1700s. Indigenous communities, particularly the Inuit, already had risk factors predisposing the spread of TB. For example, there was malnutrition from food scarcity and overcrowding on federally mandated reserves after forced relocation from traditional territories. From 1930-1940, death rates from TB in Inuit populations were roughly 700 per 100000, among the highest ever recorded in a human population. For comparison, TB was the tenth leading cause of death globally in 2016 at a crude death rate of 17 per 100000, while ischemic heart disease was the first at 126 per 100000. This led the Canadian government to forcibly relocate many Indigenous people to TB sanatoriums and "Indian hospitals," often hundreds of kilometres away. The average length of stay at these institutions was 2.5 yr and many patients never returned home

The TB health crisis persists today; in 2016, the average annual incidence rate of TB among the Inuit in Canada was roughly 296 times higher than Canadian-born non-Indigenous people. In March 2018, the national representational organization for Inuit people in Canada, called Inuit Tapiriit Kanatami (ITK), and the Government of Canada committed to reduce TB rates across Inuit communities by 50% by 2025 and to eliminate TB by 2030 in a project called the Inuit Tuberculosis Elimination Framework

It is worth noting that "Indian hospitals" were initially welcomed by many First Nations who were under the impression that reasonable healthcare was part of treaty terms. In reality, "Indian hospitals" were crowded, underfunded, and poorly staffed, serving to segregate sick Indigenous people from the rest of the population. They were also the site of the cycle of apprehension, coercive sterilization, chemical and physical restraints, and scientific experimentation. When the Canadian government began closing these hospitals in the 1960s, Indigenous people continued to fight for their right to healthcare, which was finally recognized in the Indian Health Policy of 1979

Coerced Sterilizations

Throughout the twentieth century, eugenics programs existed across the country. In the 1920s-1930s, both Alberta and British Columbia legalized eugenic policies in the Sexual Sterilization Acts which were not repealed until the 1970s. To limit reproduction of "unfit" people in the eyes of the government, Indigenous women were disproportionately targeted. This is referred to as forced or coerced sterilization and, according to various accounts by Indigenous women across the country, involved any number of the following:

- tubal ligations being performed without consent
- being falsely told that a procedure is reversible
- being pressured into signing consent forms while actively in labour or on operating tables
- being given an ultimatum to undergo a tubal ligation or risk child apprehension

It is important to note that many sterilizations also occurred outside legislation, in federally run "Indian hospitals," and some have been documented as recently as 2018. At least 100 Indigenous women have come forward with accounts of coerced sterilization by physicians and nurses, spanning from the 1970s until 2018

Sixties Scoop and Indigenous Child Welfare

The "Sixties Scoop" (Johnson, 1983) (1951-1980s) refers to the government-mandated practice of removing Indigenous children from their families without consent for placement in foster care or adoption. As residential schools started to close, many children were transitioned to child welfare facilities as the state deemed Indigenous parents unfit to care for their children – a legacy that persists today. Similar to the Indian Residential School system, the goal was to assimilate Indigenous children into a non-Indigenous family, rather than to directly provide child welfare to Indigenous communities. Though Indigenous bands have increasingly been allowed to provide their own child welfare, Indigenous children are still overrepresented in foster care. In 2016, Indigenous youth ages 0 to 4 made up about half of all foster children in private households, despite being only 8% of total youth in this age group in Canada. Youth with a history in government care may be at greater risk for substance misuse, street involvement, and incarceration

To this day, Indigenous children are disproportionately represented in the child welfare system and are often apprehended for reasons directly related to the routine conditions of poverty. The apprehensions that continue today echo the practices of the Sixties Scoop and residential school eras; the displacement of Indigenous children separates them from their language and culture and hinders the ability of Indigenous families to build resilience. Importantly, many Indigenous mothers and families avoid accessing healthcare services for fear of their children being apprehended

Indigenous Approaches to Health and Wellness

- it is important to recognize the significant diversity amongst Indigenous nations in the land now known as Canada. Even within the same nation or language group, there will be variability in practices. Despite this diversity, there are some ideas that recur across many nations
- restoring balance in the four realms of spiritual, emotional, mental, and physical health of a person acting as an individual, as well as a member of a family, community, and nation
  - ideas represented by the medicine wheel of First Nations peoples, the Learning Blanket of Inuit peoples, and the Métis tree model all share a worldview based on holistic lifelong learning and wellness
  - Indigenous medicines may take many forms (song, dance, smudge, ceremonies, plant medicines, etc.)
  - practiced by experts who have decades of apprenticeship
  - while allopathic medicine often focuses on treating illness (like HTN or DM), Indigenous medicine may understand the cause of a condition and the approach to healing in a different way than a biomedical guideline might
  - cultural humility
    - cultural humility is a respectful, person-centered way of bringing curiosity and compassion when a patient is willing to come for support
    - it takes courage to be humble enough to admit that we do not know what we do not know
    - Indigenous medicine is thousands of years old and eludes randomized controlled trials
    - Traditional Medicine is unlikely to interfere with Western Therapies
    - Latin root of "curiosity" is "cura," which means "to care." Caring about someone's healing and their beliefs about what may help them heal is a powerful act of witnessing and honouring. Beginning with the belief that a person has wisdom about themselves that no one else does and that we can be supporters of their healing, if they consent, can be a way to honour the inherent wholeness of a person seeking care
  - before assuming that an Indigenous person is interested in using traditional medicine, it is important to begin with questions and curiosity. Dr. Chantal Perrot speaks about the Patient Dignity Questionnaire which advises healthcare workers to first ask patients, "What do I need to know about you as a person to give you the best care possible?"
  - National Indigenous Health Organization (NIHO) offers 8 guidelines on practicing culturally safe health care for Indigenous patients including the need to allow Indigenous patients to access ceremony, song, and prayer; the need for information and for family support; guidelines for the appropriate disposal of body parts and for handling death

Disease Prevention

Natural History of Disease

- course of a disease from onset to resolution
  1. pathological onset
  2. presymptomatic stage: from onset to first appearance of symptoms/signs
  3. clinical manifestation of disease: may regress spontaneously, be subject to remissions and relapses, or progress to death

Surveillance

- the continuous, systematic collection, analysis, and interpretation of health-related data needed for the planning, implementation, and evaluation of public health practice

Sources: World Health Organization. Public Health Surveillance. Accessed from: https://www.who.int/topics/public_health_surveillance/en/. 2019

- types of surveillance
  - passive surveillance: reporting of disease data by all institutions that see patients, relying solely on the cooperation of health-care providers (laboratories, hospitals, health facilities, and private practitioners)
    - most common, least expensive, but difficult to ensure completeness and timeliness of data
  - active surveillance: regular visits to health facilities for reviewing medical records to identify suspected cases of disease under surveillance, or active testing of a population for the presence of a disease
    - resource-intensive, used when a disease is targeted for eradication where every possible case must be investigated, or for outbreak investigations
  - sentinel surveillance: selective reporting of disease data from a limited network of carefully selected reporting sites with a high probability of seeing cases in question,
    - well-designed system can be used to signal trends, identify outbreaks, and monitor the burden of disease in a community in a timely and cost-effective manner compared to other kinds of surveillance
    - may not be as effective in identifying rare diseases, or diseases that occur outside the catchment area of sentinel sites

Sources: World Health Organization. Public Health Surveillance. Accessed from: https://www.who.int/immunization/monitoring_surveillance/burden/vpd/surveillance_type/passive/en/; https://www.who.int/immunization/monitoring_surveillance/burden/vpd/surveillance_type/active/en/; https://www.who.int/immunization/monitoring_surveillance/burden/vpd/surveillance_type/sentinel/en/

Disease Prevention Strategies

- measures aimed at preventing the occurrence, interrupting through early detection and treatment, or slowing the progression of disease/mitigating the sequelae

Table 3. Levels of Disease Prevention

Level of Prevention	Goal	Examples
Primordial	Preventing the development of risk factors	Education that begins in childhood about behaviour that can harm health Programs that encourage physical activity
Primary	Protect health and prevent disease onset Reducing exposure to risk factors	Immunization programs (e.g. measles, diphtheria, pertussis, tetanus, polio, see Paediatrics, P5) Smoking cessation Seatbelt use See *Landmark Public Health and Preventive Medicine Trials*, PH34 for more information on VAXICOL, which details the impact of influenza vaccination of nursing home staff on mortality of residents
Secondary	Early detection of (subclinical) disease to minimize morbidity and mortality	Mammography Routine Pap smears
Tertiary	Treatment and rehabilitation of disease to prevent progression, permanent disability, and future disease	DM monitoring with HbA1c, eye exams, foot exams Medication

Source: Basic Concepts in Prevention, Surveillance, and Health Promotion. AFMC Primer on Population Health. http://phprimer.afmc.ca/Part1-TheoryThinkingAboutHealth Chapter4BasicConceptsInPreventionSurveillanceAndHealthPromotion/Thestagesofprevention

Screening (Secondary Prevention)

- "screening is a strategy used in a population to identify the possible presence of an as-yet-undiagnosed disease in individuals without signs or symptoms"
  - screening vs. case finding: screening tests are not diagnostic tests
  - the primary purpose of screening tests is to detect early disease or risk factors for disease in large numbers of apparently healthy individuals. The purpose of a diagnostic test is to establish the presence (or absence) of disease as a basis for treatment decisions in symptomatic or screen positive individuals (confirmatory test). Both screening and case finding seek to risk stratify for further investigation
  - to minimize biases and harms, and maximize benefits, screening is best done at the population level, not the individual clinical level, as part of a screening program (e.g. provincial breast cancer screening program vs. screening by primary care/family physicians)

Passive Prevention
Measures that operate without the person's active involvement (e.g. airbags in cars) are more effective than active prevention, measures that a person must do on their own (e.g. wearing a seatbelt)

Example of Primary Prevention
HPV 9-Valent Vaccine and Its Efficacy in the Prevention of Cervical Cancer
- This is a nonavalent HPV vaccine covering strains 6, 11, 16, 18, 31, 33, 45, 52, and 58
- The efficacy of this vaccine was studied in 4 randomized, double-blind, placebo-controlled trials on females between 11 and 26 yr and was found to prevent nearly 100% of precancerous cervical changes for up to 4 yr after vaccination

Does Evidence Support Supervised Injection Sites?
Can Fam Physician 2017;63(11):866
- Clinical question: Do supervised injection sites (SISs) reduce mortality, hospitalizations, ambulance calls, or disease transmission?
- Bottom line: The best evidence from cohort and modelling studies suggests that SISs are associated with lower overdose mortality (88 fewer overdose deaths per 100000 person-years (PYs)), 67% fewer ambulance calls for treating overdoses, and a decrease in HIV infections. Effects on hospitalizations are unknown

Smoking Cessation: Vaping Compared with Traditional Nicotine Replacement Therapies: a Systematic Review and Meta-analysis
BMJ Open 2021;11:e044222
Pooled results from six randomized controlled trials identified no difference in smoking cessation, the proportion of participants reducing smoking consumption, mean reduction in cigarettes smoked per day, or harms, between e-cigarettes and traditional nicotine replacement therapy. Most studies were judged to have a high risk of bias, resulting in the overall quality of evidence as low. More research is necessary prior to establishing recommendations related to e-cigarettes as smoking cessation tools.

- **types of screening**
  - **universal screening**: screening all members of a population for a disease (e.g. phenylketonuria (PKU) and hypothyroidism in all newborns)
  - **selective screening**: screening of targeted subgroups of the population at risk for a disease (e.g. mammography in women >50 yr)
  - **multiphasic screening**: the use of many measurements and investigations to look for many disease entities (e.g. periodic health exam)
- **types of bias in screening**
  - **lead-time bias**: overestimation of survival time 'from diagnosis' when the estimate is made from the time of screening, instead of the later time when the disease would have been diagnosed without screening
  - **length-time bias**: overestimation of the survival time due to screening at one time point including more stable cases than aggressive cases of disease, which may have shorter survival times

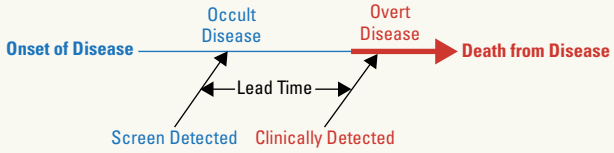

Figure 2. Lead-time bias

Table 4. Ideal Criteria for Screening Tests

Disease	Test	Health Care System
Causes significant suffering and/or death Natural history must be understood Must have an asymptomatic stage that can be detected by a test Early detection and intervention must result in improved outcomes	High sensitivity Safe, rapid, easy, relatively inexpensive Acceptable to providers and the population Continuously utilized	Adequate capacity for reporting, follow-up, and treatment of positive screens Cost effective Sustainable program Clear policy guidelines on who to treat

Adapted from: Shah CP. Public Health and Preventive Medicine in Canada, 5th ed. Toronto: Elsevier, 2003

Health Promotion Strategies

Table 5. Disease Prevention vs. Health Promotion Approach

Disease Prevention	Health Promotion
Health = absence of disease	Health = positive and multidimensional concept
Medical model (passive role)	Participatory model of health
Aimed mainly at high-risk groups in the population	Aimed at the population in its total environment
One-shot strategy aimed at a specific pathology	Diverse and complementary strategies aimed at a network of issues/determinants
Directive and persuasive strategies enforced in target groups	Facilitating and enabling approaches by incentives offered to the population
Focused mostly on individuals	Focused on a person's health status and environment
Led by professional groups from health disciplines	Led by non-professional organizations, civic groups, local, municipal, regional, and national governments

Source: Shah CP. Public Health and Preventive Medicine in Canada, 5th ed. Toronto: Elsevier, 2003

Healthy Public Policy

- purpose: to create a supportive environment to enable people to lead healthy lives, thereby making healthy choices easier for citizens
- governments and non-governmental agencies need to consider the cost and acceptability of proposed public health interventions (i.e. more invasive or costly measures should be justified by the extent of beneficial impacts on people's lives)
- the Nuffield Intervention Ladder provides one way of ranking the level of intrusion and hence a need for proportionate benefit of health promotion interventions at a population level
- methods
  - fiscal: imposing additional costs (e.g. taxes on tobacco and alcohol)
  - legislative: implementing legal deterrents (e.g. smoking bans, legal alcohol drinking age)
  - social: improving health beyond providing universally funded health care (e.g. providing affordable housing)

Source: International Conference on Health Promotion, Adelaide, South Australia (1998)

Behaviour Change

- behaviour is a result of three factors
  1. predisposing factors: knowledge, attitude, beliefs, values, intentions
  2. enabling factors: skills, supports
  3. reinforcing factors: health care professionals and the social context of family and community
- health education serves to: increase knowledge and skills and promote healthy behaviours

A Snapshot of the Opioid Crisis in Canada

Canada is experiencing a crisis of opioid-related overdose and death. Between January 2016 and September 2019, there were more than 14700 deaths in Canada related to opioids. There were also 19490 hospitalizations and 17000 emergency services. Individuals 25-34 y/o are at the greatest risk of overdose death (1 in 6 deaths), but rates have increased for all adult ages. Deaths are most commonly unintentional. Heroin, fentanyl, and hydromorphone are most commonly involved. The highest rates of opioid-related overdose and death are found in British Columbia. An estimated 300 per million British Columbians died in relation to opioid use in 2017. More died from opioids than homicide, motor vehicle accidents, and suicide combined. In 2017, deaths from opioids in Ontario ~1250, deaths from motor vehicle accidents ~450. Fentanyl or a fentanyl analogue were involved in more than 70% of cases, increased from 55% in 2016.

Sources: J Addict Med. Measuring the Burden of Opioid-related Mortality in Ontario, Canada. Latest Trends in Opioid-Related Deaths in Ontario: 1991 to 2015, Toronto: Ontario Drug Policy Research Network. Health Canada. March 2018. Opioid-related harms in Canada. Health Canada. March 2020

See Landmark Public Health and Preventive Medicine Trials table for more information on the Swedish Two-County Trial, which details the long-term effect of mammographic screening on breast cancer mortality.

Health Belief Model (1975)

- a psychological model adapted over time to explain and predict individual short- and long-term health behaviours based on one's beliefs and attitudes
- based on the assumption that one will adopt a beneficial health behaviour if 3 beliefs are present:
  - the negative health outcome is avoidable
  - expects that the health outcome can be prevented if the recommended health behaviour is adopted
  - the individual can be successful in adopting the health behaviour
- six concepts:
  - four concepts influencing one's "readiness to act" – perceived susceptibility, perceived severity, perceived benefits, perceived barriers
  - cues to action: stimuli that can trigger health action
  - self-efficacy: confidence in one's ability to take a health action

Stages of Change Model

- provides a framework in which the Health Belief Model is applied to facilitating behaviour change (e.g. quitting smoking)

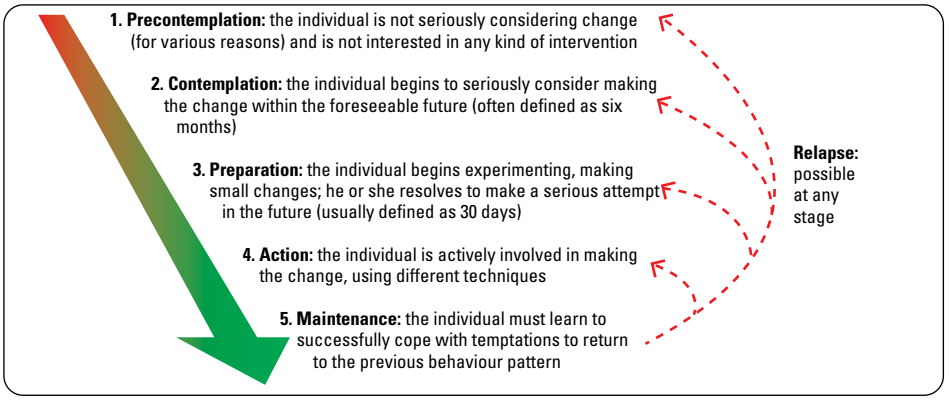

Figure 3. Stages of change model
Source: Prochaska JO, DiClemente CC, and Norcross JC. In Search of How People Change. Applications to Addictive Behaviours. Am Psychol 1992;47:1102-1114

Risk Reduction Strategies

- risk reduction: lower the risk to health without eliminating it (e.g. avoiding sun to lower risk of skin cancer)
- harm reduction: a set of strategies aimed to reduce the negative consequences of drug use and other risky behaviours (e.g. needle exchange programs)

Source: Shah, CP. Concepts, Determinants, and Promotion of Health. Public Health and Preventive Medicine in Canada, 5e. Toronto: Elsevier, 2003

Community Needs Assessment

- a community needs assessment studies a community's health gaps and pairs identification of that community's existing resources and strengths to find solutions to address those gaps. This assessment strongly values interviewing community members to gather their concerns and proposed solutions. Steps include:
  1. define the community and understand its history and demographic characteristics to formulate context for subsequent data collection
  2. understand what matters to community stakeholders (e.g. interviews, surveys, focus groups)
  3. using evidence (e.g. mortality rate, feasibility), prioritize each concern
  4. identify barriers that may prevent a concern from being addressed and propose solutions using resources available to the community

Transtheoretical Model Stages of Change for Dietary and Physical Exercise Modification in Weight Loss Management for Overweight and Obese Adults
Cochrane DB Syst Rev 2014:CD008066
Purpose: To explore the efficacy of dietary and physical activity interventions based in the transtheoretical model of change for sustained weight loss after one yr in overweight or obese adults.
Methods: RCTs comparing the use of weight loss or physical activity intervention grounded in the transtheoretical model of change to usual care for weight loss in adults who were overweight or obese were eligible for inclusion. Interventions had to be carried out by healthcare professionals or trained lay people. Weight loss or change in BMI was required as an outcome measure.
Results: Three studies including a total of 2971 participants were included in this review. Interventions grounded in this model did have positive effects on physical activity and dietary habits that included increased exercise duration and frequency, reduced fat intake, and increased fruit and vegetable consumption. The evidence for sustained weight loss at one yr was inconclusive (mean difference in favour of the transtheoretical model was between 2.1 kg and 0.2 kg at 24 mo).

Principles of Standardization

- When comparing a health measure (e.g. mortality) between two populations (or the same population at different time points) that differ in characteristics known to influence that outcome (e.g. age), standardization is used to control for the effect of that factor
- Standardization is either direct or indirect
- Indirect standardization is expressed as standardized outcome ratio. For example, Standardized Mortality Ratio (SMR) is calculated using age specific rates for a reference population, as well as age structure and total cases for a sample/known population. (e.g. an SMR of 100 signifies that deaths are at the expected level, a SMR of 110 indicates a death rate 10% higher than expected)
- Direct standardization is expressed as a rate (i.e. using age specific rates in a known/sample population against a standard population)

Measurements of Health and Disease in a Population

MEASURES OF DISEASE OCCURRENCE

Rates, Ratios, and Proportions
- a rate measures the frequency of an event in a defined population over a specific period of time (e.g. number of opioid overdoses in Canada in one year)
- a ratio compares the magnitude of one quantity to another (e.g. ratio of women to men with lupus)
- a proportion is a ratio where the numerator is a part of the denominator (e.g. proportion of deliveries complicated by placental abruption)

Incidence Rate
- number of new cases in a population over a specific period of time

Prevalence
- total number of cases in a population over a defined period of time
- two forms of prevalence
  - point prevalence: assessed at one point in time
  - period prevalence: assessed over a period of time, therefore including new cases and excluding cases that terminate (cure or death)
- a function of the incidence rate and disease duration from onset to termination
- favours the inclusion of chronic over acute cases and may underestimate disease burden if those with short disease duration are missed
- prevalence estimates are useful for measuring disease burden and therefore help in the planning of facilities and services

Age-Standardized Rate
- adjustment of the crude rate of a health-related event using a "standard" population
- standard population is one with a known number of persons in each age and sex group
- standardization prevents bias that can occur when crude rates from two dissimilar populations are compared (e.g. crude death rates over a number of decades are not comparable as the population age distribution has changed with time)
- this allows for the calculation of a Standardized Mortality Ratio (SMR), where SMR = (observed number of deaths)/(expected number of deaths)

MEASURES OF MORTALITY

Life Expectancy
- the expected number of years to be lived by a newborn based on age-specific mortality rates at a selected time

Crude Death Rate
- mortality from all causes of death per 1000 in the population

Infant Mortality Rate (IMR)
- number of reported deaths among children <1 yr of age during a given time period divided by the number of reported live births during the same time period and expressed as per 1000 live births per year

Maternal Mortality Rate (MMR)
- "number of deaths of women during pregnancy and due to puerperal causes […] per 1000 live births in the same year"

MEASURES OF DISEASE BURDEN

Potential Years of Life Lost (PYLL)
- calculated for a population using the difference between the actual age at death and a standard/expected age at death
- increased weighting of mortality at a younger age

Disability Adjusted Life Year (DALY)
- life expectancy weighted by amount of disability experienced, where 0 = perfect health and 1 = death
- both premature death and time spent with disability accounted for; these disabilities can be physical or mental
- used to assess burden of diseases in a population

Top 10 Causes of DALYs in Canada, 2019
1. Neoplasms
2. Cardiovascular diseases
3. Musculoskeletal disorders
4. Neurological disorders
5. Mental disorders
6. Other non-communicable diseases
7. Unintentional injuries
8. Chronic respiratory diseases
9. Diabetes and kidney diseases
10. Substance use disorders

Source: Global Burden of Disease Compare | Viz Hub [Internet]. Seattle (WA): University of Washington, Institute for Health Metrics and Evaluation (IHME); 2021 [cited 2021 Mar 28]. Available from: https://vizhub.healthdata.org/gbd-compare/

Quality Adjusted Life Year (QALY)
- years of life weighted by quality (utility is a proxy for quality), ranging from 0 (= death) to 1 (= perfect health). Weights are assigned based on large studies that assessed the effect of various conditions on quality of life (e.g. blindness = 0.3)
- it is possible to have "states worse than death" (e.g. QALY <0 for extremely serious conditions)
- usually used as an economic measure to assess the value for money of medical interventions

For additional rate calculations see *Steps to Control an Outbreak*, PH25
Consult the Public Health Agency of Canada for examples and latest statistics
http://www.phac-aspc.gc.ca/cphorsphc-respcacsp/2008/fr-rc/cphorsphc-respcacsp06b-eng.php

The Association of Faculties of Medicine of Canada Public Health Educators' Network. Methods: Measuring Health. AFMC Primer on Population Health

Epidemiology

Population
- a defined collection of individuals/regions/institutions/etc. (e.g. individuals defined by geographic region, sex, age)

SPIN: use a **SP**ecific test to rule **IN** a hypothesis. Note that specific tests have very few false positives. If you get a positive test, it is likely a true positive
SNOUT: use a **SEN**sitive test to rule **OUT** a hypothesis. Note that sensitive tests have very few false negatives. If you get a negative test, it is likely a true negative

Sample
- a selection of individuals from a population
- types
  - random: all members are equally likely to be selected
  - systematic: an algorithm is used to select a subset
  - stratified: population is divided into subgroups that are each sampled
  - cluster: grouped in space/time to reduce costs
  - convenience: non-random inclusion, for populations that are difficult to reach (e.g. people with precarious living conditions)

Sample Size
- increasing the sample size increases the statistical precision of the observed estimate, resulting in more narrow confidence intervals
- increasing the sample size decreases the probability of type I and type II errors
- increasing sample size does not alter the risk of bias/confounding

Bias
- systematic error leading to an incorrect estimate of the true association between exposure and outcome
- can occur at several points in study execution (e.g. collection, analysis, interpretation, publication, or review of data)
  - **selection bias**: a systematic error in the recruitment or retention of study participants
- **Berkson's bias** occurs in a case-control study using hospitalized controls, as they may not be a representative sample of the population due to the complexity that led to their hospital admission
- **non-response bias** occurs when participants differ from non-participants in a study, in that those who volunteer may be healthier
- **loss to follow-up bias** occurs when dropout rates differ between study groups and patients who dropped out are different from those who did not
  - **information bias**: the way in which information is collected about study participants is inadequate
- **recall bias** occurs when individuals with disease may be more likely to incorrectly recall/believe they were exposed to a possible risk factor than those who are free of disease
- **interviewer bias** occurs when interviewers are unblinded to outcome status and this knowledge biases their behaviour
- **observer bias** occurs when knowledge of exposure status (e.g. race, gender) biases the observer towards a diagnosis; this occurs more commonly with subjective diagnoses like those found in psychiatry

Confounder
- a variable that is related to both the exposure and outcome but is not a mediator in the exposure-outcome relationship
- distorts the estimated effect of an exposure if not accounted for in the study design/analysis (e.g. late maternal age could be a confounder in an investigation of birth order >4 and risk of developing Trisomy 21)
- randomization, stratification, matching, and regression modelling can help minimize confounding effects

Interpreting Test Results

TP = True positive TN = True negative FP = False positive FN = False negative

		Disease	
		Present	Negative
Test Result	Positive	TP	FP
	Negative	FN	TN

Sensitivity = TP/(TP+FN)
Specificity = TN/(TN+FP)

Likelihood Ratio (LR)
- Likelihood that a given test result would be expected in a patient with disease compared with the likelihood that the same result would be expected in a patient without disease
- LR+ indicates how much the probability of disease increases if the test is positive
- LR- indicates how much the probability of disease decreases if the test is negative

$$\textbf{LR+} = \frac{\text{Sensitivity}}{\text{1 - Specificity}} = \frac{[TP/TP+FN)]}{[FP/(TN+FP)]} \qquad \textbf{LR–} = \frac{\text{1 - Sensitivity}}{\text{Specificity}} = \frac{[FN/(TP+FN)]}{[TN/(TN+FP)]}$$

Positive Predictive Value (PPV)
- Proportion of people with a positive test who have the disease

$$\textbf{PPV} = \frac{TP}{TP + FP}$$

Negative Predictive Value (NPV)
- Proportion of people with a negative test who are free of disease

$$\textbf{NPV} = \frac{TN}{TN + FN}$$

		Advanced Neoplasia	
		Present	Negative
Test Result	Positive	68	147
	Negative	216	2234
	Total	284	2381

Sensitivity = 68/284 = 23.9%
Specificity = 2234/2381 = 93.8%

$$\textbf{LR+} = \frac{0.239}{1 - 0.938} = 3.85$$

$$\textbf{LR–} = \frac{1 - 0.239}{0.938} = 0.81$$

$$\textbf{PPV} = \frac{68}{(68 + 147)} = 31.6\%$$

$$\textbf{NPV} = \frac{2234}{(2234 + 216)} = 91.2\%$$

Figure 4. Interpreting test results: practical example using FOBT testing in advanced colon cancer
Source: Collins J, Lieberman D, Durbin T, et al. Accuracy of screening for fecal occult blood on a single stool sample obtained by digital rectal examination: a comparison with recommended sampling practice. Ann Intern Med 2005;142:81-85

Sensitivity
- proportion of people with disease who have a positive test

Specificity
- proportion of people without disease who have a negative test

Pre-Test Probability
- probability that a particular patient has a given disease before a test/assessment results are known

Post-Test Probability
- a revision of the probability of disease after a patient has been interviewed/examined/tested
- calculation process can be explicit using results from epidemiologic studies, knowledge of the accuracy of tests, and a nomogram/Bayes' theorem
- the post-test probability from clinical examination is the basis of consideration when ordering diagnostic tests or imaging studies
  - after each iteration, the resultant post-test probability becomes the pre-test probability when considering new investigations

Figure 5. Understanding sensitivity and specificity
Source: Loong TW. Understanding sensitivity and specificity with the right side of the brain. BMJ 2003;327:716-719

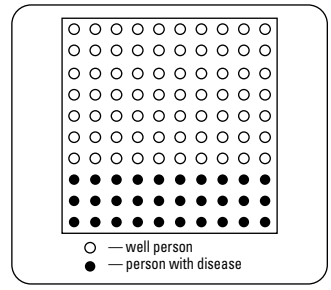

Figure 5a. Hypothetical population

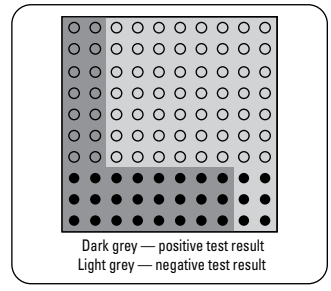

Figure 5b. Results of diagnostic test on hypothetical population

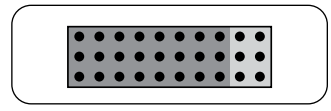

Figure 5c. Sensitivity of test (e.g. 24/30 = 80% sensitive)

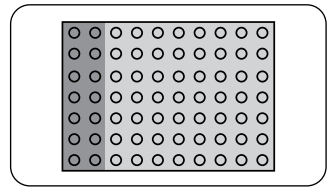

Figure 5d. Specificity of test (e.g. 56/70 = 80% specific)

- Sensitivity and specificity are characteristics of the test
- LR depends on the test characteristics, not the prevalence
- PPV and NPV depend on the prevalence of the disease in the population

Effectiveness of Interventions

Effectiveness, Efficacy, Efficiency

- three measurements indicating the relative value (beneficial effects vs. harmful effects) of an intervention
  - efficacy: the extent to which a specific intervention produces a beneficial result under ideal conditions (e.g. RCT)
    - ideal conditions include adherence, close monitoring, access to health resources, etc.
  - effectiveness: measures the benefit of an intervention under usual conditions of clinical care
    - considers both the efficacy of an intervention and its actual impact on the real world, taking into account access to the intervention, whether it is offered to those who can benefit from it, its proper administration, acceptance of intervention, and degree of adherence to intervention
  - efficiency: a measure of economy of an intervention with known effectiveness
    - considers the optimal use of resources (e.g. money, time, personnel, equipment)

Disease (e.g. lung cancer)

Exposure (e.g. smoking)	Present	Absent	Total
Present	A	B	A + B
Absent	C	D	C + D
Total	A + C	B + D	A + B + C + D

Case-Control Study

$$\text{odds ratio (OR)}^* = \frac{A}{C} \div \frac{B}{D} = \frac{A \times D}{B \times C}$$

Cohort Study

$$\frac{A}{A+B} = \text{incidence rate of health outcome in exposed} \qquad \frac{C}{C+D} = \text{incidence rate of health outcome in non-exposed}$$

$$\text{relative risk (RR)}^{**} = \frac{A}{A+B} \div \frac{C}{C+D} \qquad \text{attributable risk (AR)}^{***} = \frac{A}{A+B} - \frac{C}{C+D}$$

*Ratio of the odds in favour of the health outcome among the exposed to the odds in favour among the unexposed
**Ratio of the risk of a health outcome among exposed to the risk among the unexposed
***Rate of health outcome in exposed individuals that can be attributed to the exposure

Figure 6. Measures of effect by study type

Number Needed to Treat (NNT)

- number of patients who need to be treated to achieve one additional favourable outcome
- only one of many factors that should be taken into account in clinical or health system decision making (e.g. must take into account cost, ease, feasibility of intervention)
  - a condition with death as a potential outcome can have a higher NNT (and be acceptable), as compared to an intervention to prevent an outcome with low morbidity, in which a low NNT would be necessary

Number Needed to Harm (NNH)

- number of patients who, if they received the experimental treatment, would lead to one additional patient being harmed, compared with patients who received the control treatment

Adherence (formerly compliance)

- degree to which a patient's behaviour and lifestyle concords with the recommendations of healthcare providers (e.g. the extent to which a patient takes medications as directed)

Coverage

- extent to which the services rendered cover the potential need for these services in a community

Sources: Shah, CP. Health Indicators and Data Sources. Public Health and Preventive Medicine in Canada, 5e. Toronto: Elsevier, 2003
The Association of Faculties of Medicine of Canada Public Health Educators' Network. Assessing Evidence and Information. AFMC Primer on Population Health

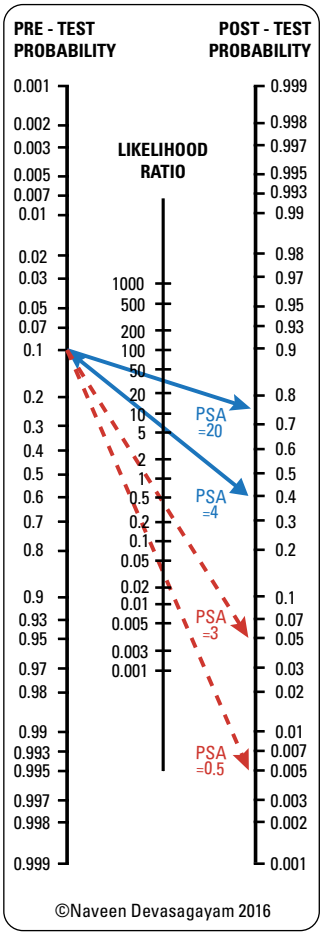

Figure 7. Fagan's likelihood ratio nomogram: practical example using PSA levels to calculate post-test probability of prostate cancer

Modified from source: Holmstrom B, Johansson M, Bergh A, et al. Prostate specific antigen for early detection of prostate cancer: longitudinal study. BMJ 2009;339:b3537

Equations to Assess Effectiveness

CER = control group event rate
EER = experimental group event rate
ARR = absolute risk reduction
RR = relative risk
NNT = number needed to treat
RR = EER/CER
ARR = CER – EER
NNT = 1/ARR

Beware

Do not be swayed by a large RR or odds ratio, as it may appear to be large if event rate is small to begin with. In these cases AR is more important (e.g. a drug which lowers an event which occurs in 0.1% of a population to 0.05% can boast a RR of 50%, and yet the AR is only 0.05%, which is not nearly as impressive)

NNT

Consult http://www.thennt.com for quick summaries of evidence-based medicine (includes NNT, LR, and risk assessments

Types of Study Design

Qualitative vs. Quantitative

Table 6. Qualitative vs. Quantitative Study Designs

Qualitative	Quantitative
Often used to generate hypotheses (Why? What does it mean?)	Often tests hypotheses (What? How much/many?)
"Bottom-up" approach	"Top-down" approach
Observation → pattern → tentative hypothesis → theory	Theory → hypothesis → observation → confirmation
Sampling approach to obtain representative coverage of ideas, concepts, or experiences	Sampling approach to obtain representative coverage of people in the population
Narrative: rich, contextual, and detailed information from a small number of participants	Numeric: frequency, severity, and associations from a large number of participants

Source: Adapted from http://phprimer.afmc.ca
Source: The Association of Faculties of Medicine of Canada Public Health Educators' Network. Assessing Evidence and Information. AFMC Primer on Population Health

Quantitative Research Methods

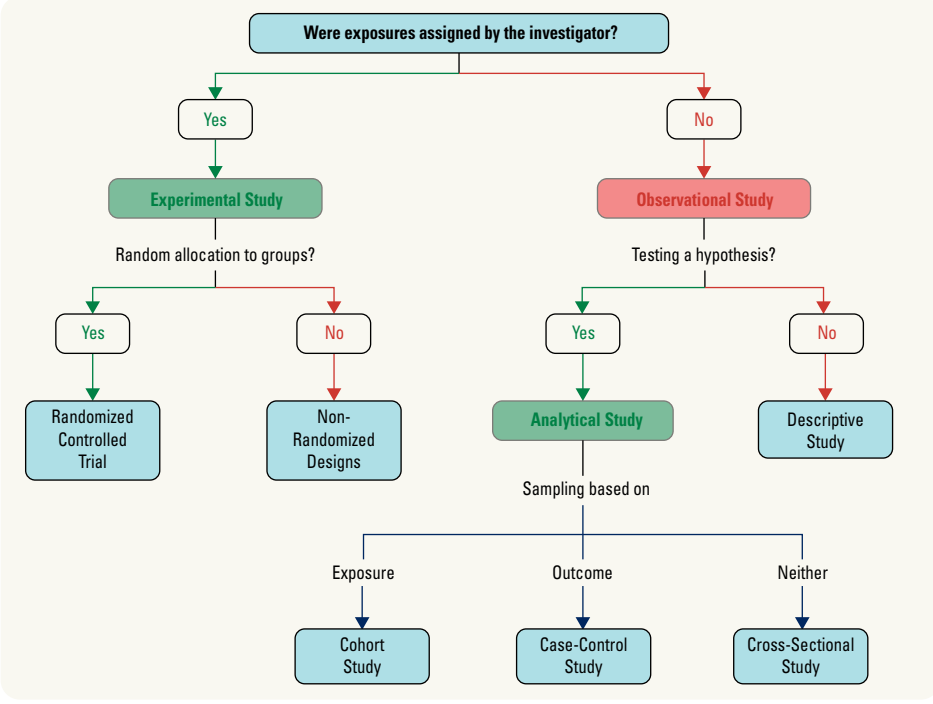

Figure 8. Quantitative study designs
Source: Adapted from http://phprimer.afmc.ca

Formulating a Research Question

PICO
Population/**P**atient characteristics
Intervention/exposure of interest
Comparison group or control group
Outcome that you are trying to prevent or achieve

Observational Study Designs

- observational studies involve neither the manipulation of the exposure of interest nor randomization of the study participants
- there are two main subtypes of observational studies: descriptive and analytic studies

Descriptive Studies

- describe the events and rates of disease with respect to person, place, and time; estimates disease frequency and time trends
- includes case reports, on one person or event, or a case series, which assesses exposures and outcomes
- can be used to generate an etiologic hypothesis and for policy planning

Analytic Studies

- observational studies used to test a specific hypothesis
- includes ecological studies, cohort studies, case-control studies, and cross-sectional studies

An ecological fallacy is an erroneous conclusion made when extrapolating population level data to explain phenomena occurring in individuals. An example of an ecological fallacy would be concluding that red wine drinking leads to lower risk of death from CVS disease based on an ecological study showing that countries with a higher rate of red wine consumption have a lower rate of death from CVS causes

Table 7. Observational Study Designs

Type of Study	Ecological	Cross-Sectional	Case-Control	Cohort
Definition	Units of analysis are populations or groups of people, rather than individuals	Use individual data on exposures and outcomes gathered at the same time	Samples a group of people who already have a particular outcome (cases) and compares them to a similar sample group without that outcome (controls)	Subjects are sampled and, as a group, classified on the basis of presence or absence of exposure to a particular risk factor
Subjects	Aggregated groups (e.g. cities)	Sample of a population	Two or more samples of individuals with and without the outcome(s) of interest (i.e. cases and controls)	One or more cohorts Cohort: group of people with common characteristics (e.g. year of birth, region of residence) Divided into measured exposed vs. unexposed groups
Methods	Descriptions of the average exposure or risk of disease for a population Can use regression models to test associations between area-level predictors and aggregate outcomes	Collect information from each person at one particular time Tabulate the numbers in groups (e.g. by presence or absence of disease/factor of interest) Make tables and compare groups Estimate prevalence Use regression models to test associations between predictors and outcomes of interest	Select sample of cases of a specific disease during a specific time frame Representative of spectrum of clinical disease Select control(s) Represent the general population To minimize risk of bias, may select more than one control group and/or match controls to cases (e.g. age, gender) Assess past exposures (e.g. EMR, questionnaire) Association can be concluded between the risk factor and the disease (odds ratio)	Collect information on factors from all persons at the beginning of the study Subjects are followed for a specific period of time to determine development of disease in each exposure group Prospective: measuring from the exposure at present to the future outcomes Retrospective: measuring forward in time from exposures in the past to later outcomes Use statistical models to test associations between exposures and disease or other measured outcomes Provides estimates of incidence, relative risk, attributable risk
Advantages	Quick, easy to do Uses readily available data Generates hypothesis	Determines association between variables Quick and uses fewer resources Surveys with validated questions allows comparison between studies	Often used when disease in population is rare (less than 10% of population) due to increased efficiency or when time to develop disease is long Less costly and time consuming	Shows an association between risk factor(s) and outcome(s) Stronger evidence for causation Can consider a variety of exposures and outcomes
Disadvantages	Poor generalizability to individual level (not direct assessment of causal relationship) Ecological fallacy: an incorrect inference from groups to individuals Confounding	Does not allow for assessment of temporal relationship or offer strong evidence for causation between variables Confounding Selection bias Recall bias (see *Bias*, PH14)	Recall bias (see *Bias*, PH14) Confounding Selection bias for cases and controls Only one outcome can be measured	Confounding may occur due to individuals self-selecting the exposure, or unknown/unmeasured factors are associated with the measured exposure and outcome Cost and duration of time needed to follow cohort Selection bias
Examples	A study looking at the association between smoking rates and lung cancer rates in different countries at the population level without individual data on both factors	A study that examines the distribution of BMI by age in Ontario at a particular point in time	A famous case control study published by Sir Richard Doll demonstrated the link between tobacco smoking exposure and lung cancer cases at the individual level	A famous cohort study is the Framingham Heart Study, which assessed the long-term cardiovascular risks of diet, exercise, and medications such as ASA, etc.

Experimental Study Designs

- not discussed here are non-randomized controlled trials (e.g. allocation by clinic or other non-random basis – performed when randomization is not possible)

RANDOMIZED CONTROLLED TRIAL (RCT)

Definition

- participants are assigned by random allocation to two or more groups, one of which is the control group, the other group(s) receive(s) an intervention

Participants
- individuals are selected using explicit inclusion/exclusion criteria and recruitment targets are guided by sample size calculations

Methods
- random allocation of individuals into two or more treatment groups through a centralized concealed process
- method of assessment to reduce bias
  - single-blind: participant does not know group assignment (intervention or placebo)
  - double-blind: participant and observer both unaware of group assignment
  - triple-blind: participant, observer, and analyst unaware of group assignment
- control group receives standard of care or placebo if no standard of care exists
- one or more group(s) receive(s) the intervention(s) under study
- baseline covariate(s) and outcome(s) are measured and the groups are compared
- all other conditions are kept the same between groups

Advantages
- "gold standard" of studies, upon which the practice of EBM is founded
- provides the strongest evidence for effectiveness of intervention
- threats to validity are minimized with sufficient sample size and appropriate randomization
- randomization is one of few methods that can eliminate confounding (including unmeasured confounders) and self-selection bias
- allows prospective assessment of the effects of intervention

Disadvantages
- some exposures are not amenable to randomization (e.g. cannot randomize participants to poverty/wealth or to harmful exposures such as smoking) due to ethical or feasibility concerns
- can be difficult to randomly allocate groups (e.g. communities, neighbourhoods)
- difficult to study rare events, since RCTs require extremely large sample sizes
- contamination, co-intervention, and loss to follow-up can all limit causal inferences
- can have poor generalizability (e.g. when trial participants are healthier than the average patient population)
- costly

Summary Study Designs

META-ANALYSIS

Definition
- a form of statistical analysis that aggregates all relevant studies addressing the same research question in order to increase statistical precision

Participants
- all the studies identified through a systematic literature review

Methods
- selection of relevant studies from the published literature which meet quality criteria
- statistical models used to combine the results of each independent study
- provides a summary statistic of overall results as well as graphic representation of included studies (forest plot)

Advantages
- attempts to overcome the problem of reduced power due to small sample sizes of individual studies
- can address questions (e.g. subgroup analyses) that the original studies were not powered to answer

Disadvantages
- studies may be heterogeneous and therefore inappropriate to combine (e.g. different patient populations, exposure classification/measurement, outcome assessment)
- reliance on published studies may increase the potential conclusion of an effect as it can be difficult to publish studies that show no significant results (publication bias)

Sources: Shah, CP. Measurement and Investigation. Public Health and Preventive Medicine in Canada, 5e. Toronto: Elsevier, 2003
The Association of Faculties of Medicine of Canada Public Health Educators' Network. Assessing Evidence and Information. AFMC Primer on Population Health

Analysis
Per-Protocol Analysis (PP)
Strategy of analysis in which only patients who complete the entire study are counted towards the results

Intention-to-Treat Analysis (ITT)
When groups are analyzed exactly as they existed upon randomization (i.e. using data from all patients, including those who did not complete the study)

An example of an RCT is the SPARCL trial, which demonstrated intense lipid-lowering with atorvastatin reduces the risk of cerebro- and cardiovascular events in patients with and without carotid stenosis when compared to placebo

An example of a meta-analysis is one that compares the effects of ACEIs, calcium channel blockers, and other antihypertensive agents on mortality and major cardiovascular events by compiling and analyzing data from a full set of reported RCTs

Methods of Analysis

Distributions

- a distribution describes the frequency at which each value (or category) occurs in a study population
- distributions can take characteristic shapes. i.e. normal (Gaussian) or non-normal (binomial, gamma, skewed, etc.)
- characteristics of the normal distribution
  - mean = median = mode
  - 68% of observations fall within one standard deviation of the mean
  - 95% of observations fall within two standard deviations of the mean
- measures of central tendency
  - mean: sum of each observation's data (e.g. ages) divided by total number of observations
  - median: value of the 50th percentile; a better reflection of the central tendency for a skewed distribution
  - mode: most frequently observed value in a series
- measures of dispersion
  - range: the largest value minus the smallest value
  - variance: a measure of the spread of data
  - standard deviation: the average distance of data points from the mean (the positive square root of variance)
- given the mean and standard deviation of a normal or binomial distribution curve, a description of the entire distribution of data is obtained

Consult the Cochrane Library of Systematic Reviews (http://www.cochranelibrary.com) for high-quality systematic reviews and meta-analyses

Example Calculation
Data set: 17, 14, 17, 10, 7
Mean = (17 + 14 + 17 + 10 + 7) ÷ 5 = 13
Median (write the list in order, median is the number in the middle) = 7, 10, 14, 17, 17 = 14
Mode (number repeated most often) = 17
Range = 17 – 7 = 10
Variance = [(17 – 13)2 + (14 – 13)2 + (17 – 13)2 + (10 – 13)2 + (7 – 13)2] ÷ 5 = 19.5
Standard Deviation = √variance = √19.5 = 4.42

Data Analysis

Statistical Hypotheses

- null (H_0)
  - the default hypothesis; often states there is no relationship between two variables
- alternative (H_1)
  - the hypothesis that we are interested in; often states there is a relationship between two variables
  - we can find evidence against H_0 but we can never 'prove' H_1

Type I Error (α Error)

- the null hypothesis is falsely rejected (i.e. concluding an intervention X is effective when it is not, or declaring an observed difference to be real rather than by chance)
- the probability of this error is denoted by the p-value
- studies tend to be designed to minimize this type of error, since a type I error can have larger clinical significance than a type II error
- i.e. in a study exploring a drug's effectiveness on lowering blood pressure, the data may indicate the drug is effective and therefore lowers blood pressure, when in reality the drug is ineffective

Type II Error (β Error)

- the null hypothesis is falsely accepted (i.e. stating intervention X is not effective when it is, or declaring an observed difference/effect to have occurred by chance when it is present)
- by convention a higher level of error is often accepted for most studies
- can also be used to calculate statistical power
- i.e. in a study exploring the effectiveness of a COVID-19 vaccine, the data suggests the vaccine is ineffective and therefore does not protect against COVID-19 infection, when in reality it does

Power

- probability of correctly rejecting a null hypothesis when it is, in fact, false (i.e. the probability of finding a specified difference to be statistically significant at a given p-value)
- power increases with an increase in sample size
- power = 1 – β, and is therefore equal to the probability of a true positive result

Statistical Significance

- the probability that the statistical association found between variables is due to random chance alone (i.e. there is no association)
- the preset probability is set sufficiently low that one would act on the result; frequently $p<0.05$
- when statistical tests result in a probability less than the preset limit, the results are said to be statistically significant (denoted by the α-value)

Clinical Significance

- measure of clinical usefulness (e.g. 1 mmHg BP reduction may be statistically significant, but may not be clinically significant)
- depends on factors such as cost, availability, patient adherence, and side effects in addition to statistical significance

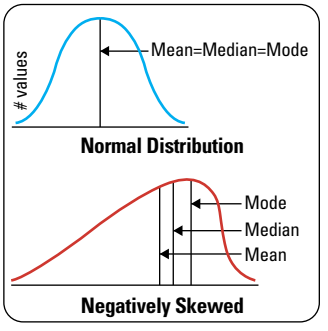

Figure 11. Distribution curves

Type I (α) Error
"There Is **A**n **E**ffect" where in reality there is none

Confidence Interval (CI)
- provides a range of values within which the true population result (e.g. the mean) lies, bounded by the upper and lower confidence limits
- frequently reported as 95% CI (i.e. if this study were repeated 100 times, estimates would fall within the 95% CI 95 out of 100 times)

A wider confidence interval implies more variance than a tighter confidence interval given the same critical value

Data
- there are 2 types of quantitative data
  - continuous data (e.g. height in cm)
  - discrete data (e.g. number of patients in the ICU)
- information collected from a sample of a population
- there are 4 overall levels of measurement for quantitative data
  - categorical (e.g. blood type, marital status)
  - ordinal (e.g. low, medium, high)
  - interval (e.g. °C, time of day)
  - ratio (e.g. serum cholesterol, hemoglobin, age)

Validity/Accuracy (of a measurement tool)
- how closely a measurement reflects the entity it claims to measure

Reliability/Precision
- how consistent multiple measurements are when the underlying subject of measurement has not changed
- may be assessed by different observers at the same time (inter-rater reliability) or by the same observer under different conditions (test-retest reliability)

Internal Validity
- degree to which the findings of the sample truly represent the findings in the study population
- dependent on the reliability, accuracy, and absence of other biases

External Validity (i.e. Generalizability)
- degree to which the results of the study can be generalized to other situations or populations

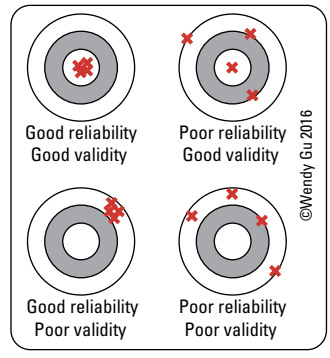

Figure 12. Validity vs. reliability

What's the difference between Pearson and Spearman correlation?
Different types of correlation are used for different levels of measurement. Pearson is for continuous and Normal data, Spearman is for ordinal or non-Normal data. There are other forms of correlation for other levels of measurement (e.g. tetrachoric/polychoric)

Common Statistical Tests

Table 8. Statistical Tests

	Two-sample Z-Test	Analysis of Variance (ANOVA)	Chi-Squared Test ($\chi 2$)	Linear Regression	Logistic Regression	Pearson Product-Moment Correlation (Pearson's r)
What are you trying to show?						
	Compare the mean values of an outcome variable between two groups (e.g. difference in average BP between men and women)	Compare the mean values of an outcome variable between two or more groups (e.g. difference in average BP between persons in three towns)	Test the correspondence between a theoretical frequency distribution and an observed frequency distribution (e.g. if one sample of 20 patients is 30% hypertensive and another comparison group of 25 patients is 60% hypertensive, a chi-squared test determines if this variation is more than expected due to chance alone)	Looks at associations between two or more variables (e.g. age and BP)	Shows how a change in one explanatory variable affects the status (e.g. ill vs. non-ill) of the outcome variable	Assesses the strength of the linear relationship between two variables. Ranges from -1 (perfect negative association, i.e. increases in one variable are associated with decreases in another) to 1 (perfect positive association, increases in one variable are associated with increases in the other). A correlation of 0 indicates no relationship
What kind of variables do you measure?						
Dependent Variable	Continuous	Continuous	Categorical (2 or more)/ordinal	Continuous	Categorical (outcomes usually dichotomous)	Continuous
Independent Variable	Dichotomous	Categorical/Ordinal (2 or more)	Categorical/Ordinal (2 or more)	Continuous/Ordinal/ Categorical	Continuous/Ordinal/ Categorical	Continuous
Assumptions	Data follow a normal/t-distribution Equal variances Data are independent	"Normal" distribution of dependent variable's error term Data are independent	Expected counts must be at least 5 for all cells in n by n table Data are independent	Dependent variable's error term has "normal" distribution Linear relationship between variables Homoscedasticity No influential values Data are independent	Linearity (on logit scale) No influential values Model has adequate goodness-of-fit Data are independent	Underlying relationship is linear Data for both variables are normally distributed Data are independent

Causation

Criteria for Causation (Bradford Hill Criteria)

1. **strength of association**: the frequency with which the factor is found in the disease, and the frequency with which it occurs in the absence of disease
2. **consistency**: is the same relationship seen with different populations or study design?
3. **specificity**: is the association particular to your intervention and measured outcome?
4. temporal relationship: did the exposure occur before the onset of the disease?
5. **biological gradient**: finding a dose-response relationship between the exposure-outcome
6. **biological plausibility**: does the association/causation make biological sense?
7. **coherence**: can the relationship be explained/accounted for based on what we know about science, logic, etc.?
8. **experimental evidence**: does experimental evidence support the association (e.g. is there improvement?)
9. **analogy**: do other established associations provide a model for this type of the relationship?

Note: Not all criteria must be fulfilled to establish scientific causation, and the modern practice of EBM emphasizes 'experimental evidence' as superior to other criteria for experimental causation review. However, many causation questions in health cannot be answered with experimental methods

Source: Bradford Hill A. The environment and disease: association or causation. Proc R Soc Med 1965;58(5):295-300.

Assessing Evidence

- critical appraisal is the process of systematically examining research evidence to assess validity, results, and relevance before using it to inform a decision

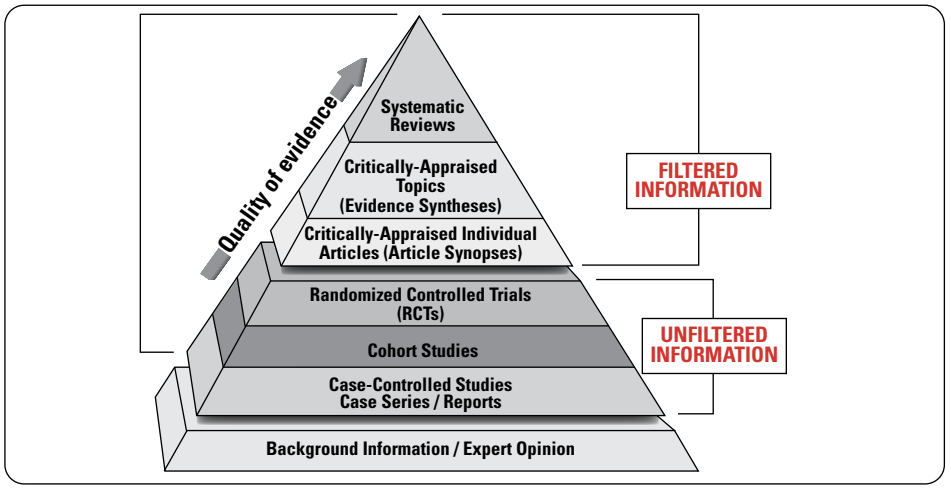

Figure 13. Pyramid of pre-appraised evidence

© Copyright 2006. Trustees of Dartmouth College & Yale University. All rights reserved. Produced by Glover J., Izzo D., Odato K., and Wang L

A. Are the results of the study valid?

- see below for classifications of evidence that has already been assessed; see sidebar for assessing primary studies

B. What are the results?

- what was the impact of the treatment effect?
- how precise was the estimate of treatment effect?
- what were the confidence intervals and power of the study?

C. Will the results help me in caring for my patients?

- are the results clinically significant?
- can I apply the results to my patient population?
- were all clinically important outcomes considered?
- are the likely treatment benefits worth the potential harm and costs?

Levels of Evidence: Classifications Cited in Guidelines/Consensus Statements

Level I evidence: based on RCTs (or meta-analysis of RCTs) big enough to have low risk of incorporating FP or FN results

Level II evidence: based on RCTs too small to provide Level I evidence; may show positive trends that are non-significant, or have a high risk of FN results

Level III evidence: based on non-randomized, controlled or cohort studies; case series; case-controlled; or cross-sectional studies

Level IV evidence: based on opinion of respected authorities or expert committees, as published consensus conferences/guidelines

Level V evidence: opinions of the individuals who have written/reviewed the guidelines (i.e. Level IV evidence), based on experience/-knowledge of literature/peer discussion

Notes: These 5 levels of evidence are not direct evaluations of evidence quality or credibility; they reflect the nature of the evidence. While RCTs tend to be most credible (with <III), level III evidence gains credibility when multiple studies from different locations and/or time periods report consistent findings. Level IV and V evidence reflects decision-making that is necessary but in the absence of published evidence.

Figure 14. Levels of evidence classifications
Note: This is only one method of classifying evidence. Various systems exist, but operate within the same premise that certain types of evidence carry more weight than others

Health System Planning and Quality

Continuous Quality Improvement

Quality Improvement (QI)
- a means of evaluating and improving processes; focusing more on systems and systematic biases, which are thought to cause variation in quality
- measures to increase efficiency of action with the purpose of achieving optimal quality

Quality Assurance
- process to guarantee the quality of health care through improvement and attainment of set standards
- **"five-stage process of quality assurance"**

Source: Public Health and Preventive Medicine in Canada, Shah

1. formulation of working goals
2. procedural changes to implement those goals
3. regular comparison of current performance with original goals
4. development of solutions to bring performance closer to goals
5. documentation of quality assurance activities

Quality Control
- a process of surveying the quality of all factors involved in the process to maintain standards

Continuous Quality Improvement
- the process of ongoing service/product refinement via the vigilant review of expectant issues detrimental to the system and regular incorporation of improvements

Quality Management
- combination of several processes (assurance, control, improvement) to maintain consistent quality

Total Quality Management
- management principle for advancing quality while minimizing additional expenditures
- focuses on the entire system rather than discrete elements

Audit
- methodical analysis of a quality system by quality auditors
- to determine whether quality processes and results comply with goals, and whether processes have been implemented effectively

Systems Analysis Tools
1. **5 Whys**: brainstorming to simplify the process of change; continue asking 'why' until the root of the problem is discovered
2. **Ishikawa Diagrams** (i.e. Fishbone Diagrams): identify generic categories of problems that have an overall contribution to the effect
3. **Defect Check Sheets**: consider all defects and tally up the number of times the defect occurs
4. **Pareto Chart**: x vs. y chart; x-axis = defect categories, y-axis = frequency; plot cumulative frequency on the right y-axis; purpose is to highlight most important among large set of factors contributing to defects/poor quality

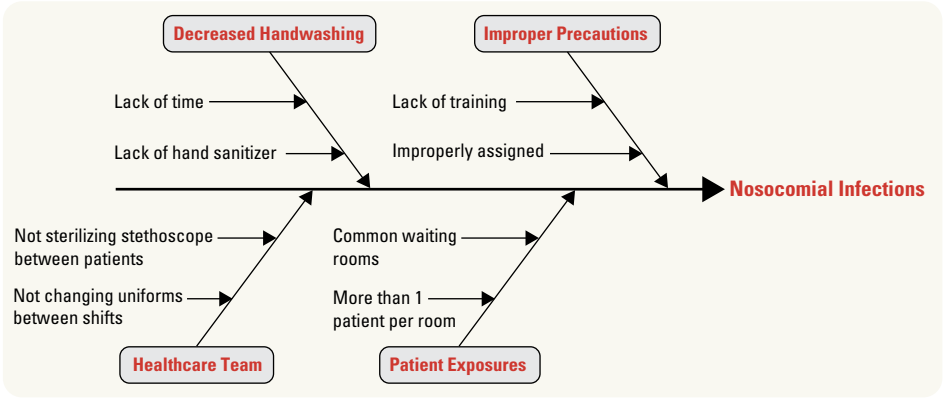

Figure 15. Ishikawa diagram

Precede-Proceed Model

- tool for designing, implementing, and evaluating health interventions/programs

Table 9. Precede-Proceed Model

PRECEDE Phase	PROCEED Phase
Phase 1 – Identify the ultimate desired result	Phase 5 – Implementation (design and conduct the intervention)
Phase 2 – Identify health issues and their behavioural and environmental determinants. Set priorities among them	Phase 6 – Process evaluation (determine if the program is implemented as planned)
Phase 3 – Identify the predisposing, enabling, and reinforcing factors that affect the behaviours and environmental determinants	Phase 7 – Impact evaluation (measure intermediate effects on the target population)
Phase 4 – Identify the administrative and policy factors that influence what can be implemented	Phase 8 – Outcome evaluation (determine whether the original desired result was achieved)

Planning Cycles/Models

1. **APIE Planning Model**: *Assessment, Planning, Implementation, Evaluation*
2. **PDSA Planning Cycle**: *Plan, Do, Study, Act*

Cost Analysis

Cost Benefit Analysis (CBA)

- an analysis which compares the total expected costs with the total expected benefits of actions in order to choose the most profitable or beneficial option(s)
- costs are controlled for inflation and market changes so that the effect of the change is evaluated over a consistent, preset financial value

Cost Effectiveness Analysis (CEA)

- ratio of change in cost (numerator) to change in effect (denominator) in response to a new strategy or practice
  - the numerator highlights the cost of the health gain
  - some examples of changes in effect (denominator) could be years of life gained or sight-years gained
  - the most commonly used outcome measure is quality-adjusted life years (QALY) (see *Quality Adjusted Life Year*, PH14)
- can be used where an extensive cost benefit analysis is not applicable or appropriate

Managing Disease Outbreaks

Definitions

Outbreak
- incidence of new cases beyond the usual frequency of disease in a population or community in a given time

Endemic
- consistent existence of infectious agent or disease in a given population or area (i.e. usual rate of disease)

Epidemic
- an increase, often sudden, in cases of a disease above what is usually expected in a particular population (e.g. SARS epidemic)
- can occur due to a recent increase in the virulence or amount of an agent, introduction of a new agent to an area, enhanced mode of transmission of the agent, altered host response, and/or increased host susceptibility through more exposure or portals of entry

Pandemic
- epidemic that has spread across international or intercontinental boundaries, affecting a large number of people (e.g. COVID-19 pandemic)

Attack Rate
- proportion of an initially disease-free population that develops the disease over a specified time period
- = [(# of new cases of disease) / (initial population size)] * 100%

Secondary Attack Rate
- the proportion of individuals who develop disease as a result of exposure to primary contacts during the incubation period
- = [(total # of cases - initial # of cases) / (# of susceptible individuals - initial # of cases)] * 100%
- measure of infectiousness, which reflects the ease of disease transmission

Virulence
- measure of an infectious agent to cause significant sickness
- = (# of cases that are severely ill or died) / (total # of cases)

Case-Fatality Rate (CFR)
- proportion of individuals with the disease who died as a result of the illness during a specified time period
- must be clearly differentiated from the mortality rate

Mortality Rate
- proportion of the population that died from any cause during a specified time period
- crude mortality rate (unadjusted for age)

Basic Reproduction Number (R_0)
- the average number of secondary infections that arise from one infection
- can only be calculated in a susceptible population

Steps to Control an Outbreak

Infection Control Precautions

Contact (e.g. impetigo, chicken pox, warts)
- wash hands
- gloves
- gown
- wipe equipment after use

Droplet (e.g. influenza, mumps, pneumonia)
- contact precautions PLUS
- goggles/face shield
- surgical mask

COVID-19 precautions
Precautions include hand hygiene, gown, eye protection, and well-fitting masks (e.g. surgical mask). N95 respirators are reserved for aerosol-generating procedures, such as endotracheal intubation and bronchoscopy
For specific examples, see "Communicable Diseases" section in: Shah CP. Public health and preventive medicine in Canada. 5th ed. Toronto: Elsevier; 2003
Source: Public Health Ontario: https://www.publichealthontario.ca/-/media/documents/ncov/ipac/ipac-additional-precautions-acute-care.pdf?la=en

Active Surveillance
Outreach such as visits or phone calls by the public health/surveillance authority to detect unreported cases (e.g. an infection control nurse goes to the ward and reviews temperature charts to see if any patient has a nosocomial infection)

Passive Surveillance
A surveillance system where the public health/surveillance authority depends on others to submit standardized forms or other means of reporting cases (e.g. ward staff notify infection control when new cases of nosocomial infections are discovered)

Canada's Response to the COVID-19 Pandemic
- In late 2019, the novel coronavirus (COVID-19) led to a global pandemic
- By May 2020, there were over 70000 cases in Canada and more than 4.3 million cases worldwide
- Symptoms of the virus varied from dry cough, fever, and fatigue, to more severe respiratory symptoms such as dyspnea and chest pain
- PHAC developed the following response:
  - Development and implementation of new diagnostic tests based on the genetic sequence of COVID-19
  - Prompt identification, risk assessment, management, and placement of confirmed cases by healthcare professionals
  - Application of routine practices and additional precautions for healthcare workers: gloves, long-sleeved gowns, facial protection, and masks
  - Enforcement of national physical distancing protocols and 14-day self-isolation for those returning from international travel
  - Free vaccines against COVID-19 were made available to everyone in Canada over the course of 2021
  - The temporary closure of many institutions and reduction in income for millions of Canadians resulted in novel social assistance programs, such as the Canada Emergency Response Benefit

Source: Government of Canada. Coronavirus (COVID-19): Canada's Response [Internet]. Ottawa (ON): Government of Canada; 2020 [updated 2020 Jun 18; cited 2020 Jun 20]. Available from: https://www.canada.ca/en/public-health/services/diseases/2019-novel-coronavirus-infection/canadas-reponse.html?topic=tilelink

Airborne (e.g. TB)
- contact precautions PLUS
- N95 mask (fit-tested)
- negative pressure room

Table 10. Ten-Step Approach

Steps	Details
1. Identify the investigation team and resources	Local public health units (e.g. Toronto Public Health)
	Federal level (e.g. PHAC)
2. Establish existence of an outbreak	Compare the number of cases during the suspected outbreak to the number of cases expected during a non-outbreak time frame (e.g. receiving a report of a vomiting baseball team after a team dinner at a restaurant)
3. Verify the diagnosis	Obtain medical records and lab reports Conduct further clinical testing as needed
4. Define a case	3 components: Person, Place, Time (e.g. "Diagnosis A: Person with XYZ signs and symptoms… Occurred after visiting X… During months/year")
5. Find cases systemically and create a line listing	A line listing should include clinical information (signs/symptoms, onset times/dates), demographic information, exposure information
6. Perform descriptive epidemiology and develop hypotheses	Create epidemic curves (see Figure 16)
7. Evaluate hypotheses and conduct additional studies as needed	Case-control studies: useful when not everyone exposed can be found and included in the study
	Cohort studies: useful when all persons exposed can be included in the study
8. Implement control measures	Can occur at any stage in an outbreak (e.g. isolation)
9. Communicate findings	Involve the media to address public concerns and call for public action
10. Continue surveillance	Determine when the outbreak is over Document the effectiveness of control measures

Source: Adapted from Moore Z. Outbreak Investigations: The 10-Step Approach [Internet]. North Carolina: Government of North Carolina; [updated 2019 Dec 16; cited 2020 Jun 20]. Available from: https://epi.dph.ncdhhs.gov

Infection Control Targets

- interventions should target host, agent, environment, and their interactions

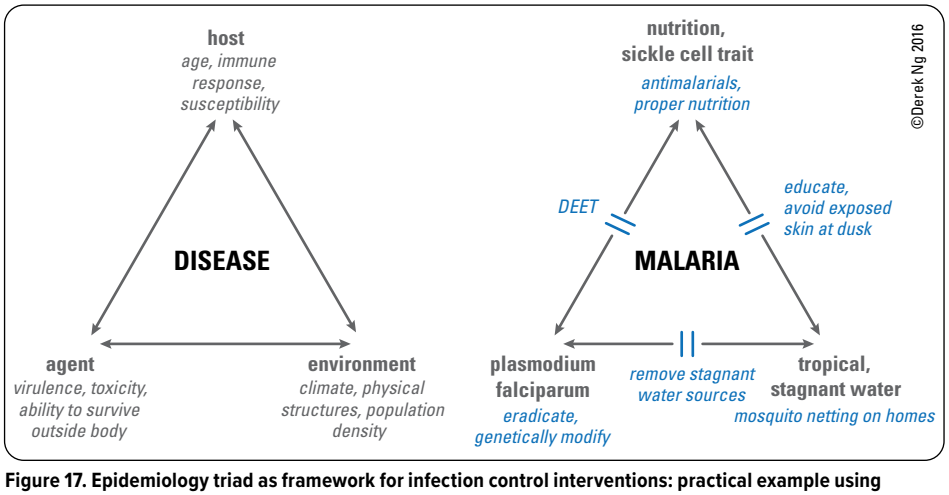

Figure 17. Epidemiology triad as framework for infection control interventions: practical example using malaria

The International Health Regulations (IHR)
- an international agreement involving 196 nations to prevent, protect against, control, and provide a public health response to pandemics
- a public health emergency of international concern (PHEIC) is "an extraordinary event which is determined to constitute a public health risk to other States through the international spread of disease and to potentially require a coordinated international response"
- the IHR Emergency Committee provides the WHO Director-General with temporary recommendations on PHEIC events

Figure 16. Epidemic curves

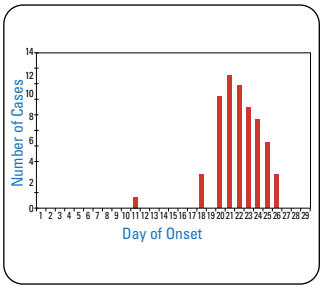

Figure 16a. Point source epidemic curve

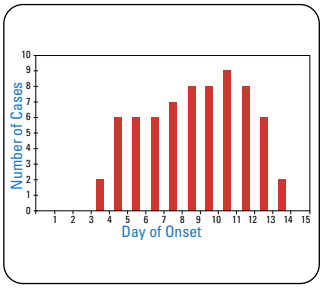

Figure 16b. Extended continuous source epidemic curve

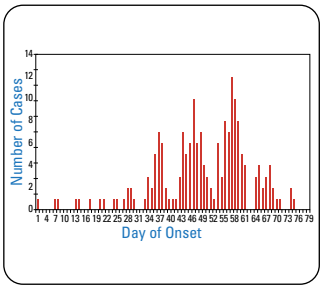

Figure 16c. Propagated source epidemic curve

Environmental Health

Definition
- study of the association between environmental factors, both constructed and natural, and health
- environmental exposures
  - four common hazards: chemical, biological, physical, and radiation
  - four main reservoirs: air, food, water, and soil
  - three main routes: inhalation, ingestion, or absorption (skin)
- usually divided into two main settings
  - workplace (including schools): may see high level exposure in healthy individuals (see *Occupational Health*, PH30)
  - non-workplace: lower levels of exposure over a longer period of time; affects vulnerable populations more severely, such as at extremes of age, and the immunosuppressed; may be teratogenic
- health impacts of the environment also include factors such as urban planning and how individuals interact with the built environment (e.g. safe pedestrian and bicycle paths can facilitate more active lifestyles)

Table 11. Environmental Health Jurisdiction

Public Health Unit	Enforcement of water and food safety regulations (including restaurant food safety) Assessment of local environmental risks Monitoring and follow-up of reportable diseases Investigation of environmental contamination, clusters of disease
Municipal Government	Waste disposal, recycling, water and sewage treatment/collection/distribution
Provincial and Territorial Government	Water and air quality standards Industrial emission regulation Toxic waste disposal
Federal Government	Designating and regulating toxic substances Regulating food products (e.g. Health Canada (drugs), Canadian Food Inspection Agency (CFIA)) Setting policy for pollutants that can travel across provincial boundaries
International	Multilateral agreements (e.g. Kyoto Protocol, UN Convention on Climate Change, International Joint Commission)

Source-Path-Receiver Model
- to prevent workplace injuries, strategies can be implemented to improve the safety profile of the source, modify the path, and/or protect the receiver

Environmental Risk Assessment

Hazard Identification and Risk Assessment (HIRA)

Hazard Identification
- what is the hazard involved?
- assess potential hazards by taking environmental health history

Risk Characterization
- is the identified agent likely to elicit the patient's current symptoms?
- review known health impacts of the hazard and identify specific properties that contribute to or diminish adverse effects (e.g. evaluate hazard threshold levels)

Exposure Assessment
- is the patient's exposure to the environmental agent sufficient to have caused the current symptoms?
- quantify exposure through direct measurement or by reviewing frequency and nature of contact with hazard

Adapted from p.250, Sixth Edition of A Dictionary of Epidemiology by Miquel Porta

Air

Biological Hazards
- moulds thrive in moist areas; 10-15% of the population is allergic
- bacteria survive as spores and aerosols, can be distributed through ventilation systems (e.g. *Legionella*)
- dust mites (yr-round) and pollens (seasonal) can trigger upper- and lower-airway symptoms

Chemical Hazards
- ground-level ozone
  - main component of smog with levels increasing in major cities
  - worsens asthma, irritates upper airway

Environmental Health Jurisdiction - Taking an Environmental Health History
CMAJ 2002; 166(8):1049-1055

CH2OPD2
Community
Home
Hobbies
Occupation
Personal habits
Diet
Drugs

BPA, The Toxin Concern of 2009
Bisphenol A (BPA) is a chemical compound found in some hard, clear, lightweight plastics and resins. According to the NIH, animal studies suggest that ingested BPA may imitate estrogen and other hormones. In October 2008, Canada became the first country in the world to ban the import and sale of polycarbonate baby bottles containing BPA, stating that although exposure levels are below levels that cause negative effects, current safety margins need to be higher. The US FDA does not consider normal exposure to BPA to be a hazard, however the NIH has some concern that fetuses, infants, and children exposed to BPA may be at increased risk for early-onset puberty, prostate, and breast cancer

Cannabis Legalization and Driving Under the Influence of Cannabis (DUIC)
Source: Public Health Ontario. Evidence Brief-Driving Under the Influence of Cannabis, 2017
Since the Government of Canada stated its commitment to legalize cannabis via the Cannabis Act (Bill C-45) on April 13, 2017, the Canadian Task Force on Cannabis Legalization and Regulation specifically noted driving impairment as an important consideration. Higher cannabis use, cannabis-dependence, lower perceived risk from DUIC and normative beliefs about DUIC were identified as risk factors. As such, an act to amend the Criminal Code Bill C-46 was simultaneously introduced to enable the police to request an oral fluid sample for roadside drug screening and to implement THC per se whole blood limits (>2 ng/mL punishable). Public health was also advised to devise population-based interventions such as 6 hour waiting period recommendations before driving, as well as preventive strategies through addiction services, mass-media campaigns, and school-based instructional programs

- carbon monoxide (fossil fuel-related, common byproduct of combustion)
  - aggravates cardiac disease at low levels
  - headache, nausea, dizziness at moderate levels
  - fatal at high levels
- sulphur dioxide (fossil fuel-related), nitrogen oxides
  - contribute to acid rain and exacerbate breathing difficulties
- organic compounds at high levels (e.g. benzene, methylene chloride, tetrachloroethylene)
  - tend to be fat-soluble, easily absorbed through skin, and difficult to excrete
- heavy metal emissions (e.g. nickel, cadmium, chromium)
  - variety of health effects: upper airway disease, asthma, decreased lung function
- second-hand tobacco smoke
  - respiratory problems, increased risk of lung cancer
  - particulates associated with decreased lung function, asthma, upper airway irritation

Radiation Hazards
- sound waves
- ionizing radiation
  - radon is naturally produced by soil containing uranium or radium; can contaminate indoor air, and is associated with ~20% of lung cancers
- ultraviolet radiation is increasing due to ozone layer destruction and increases risk of skin cancer
- non-ionizing radiation
  - visible light, infrared, microwave

Water

Biological Hazards
- mostly due to human and animal waste
- Indigenous peoples, Black Nova Scotians, and rural Canadians at higher risk
- bacteria: *Escherichia coli* (e.g. Walkerton, ON), *Salmonella, Pseudomonas, Shigella*
- protozoa: *Giardia, Cryptosporidium* (e.g. North Battleford, SK)

Chemical/Industrial Hazards
- chlorination by-products (e.g. chlorinated water can cause cancer at high levels)
- volatile organic compounds, heavy metals, pesticides, and other industrial waste products can be present in groundwater
- mercury from fish (exposure during pregnancy can be neurotoxic for the fetus)
- asbestos (e.g. from old buildings)
- lead (can be found in paint, older buildings, and traditional medicines in dangerous quantities)

Soil

Biological Hazards
- biological contamination: tetanus, *Pseudomonas*

Chemical Hazards
- contamination sources: rupture of underground storage tanks, use of pesticides and herbicides, percolation of contaminated water runoffs, leaching of wastes from landfills, dust from smelting and coal burning power plants, residue of industrial waste/development (e.g. urban agriculture), lead deposition, leakage of transformers
- most common chemicals: petroleum hydrocarbons, solvents, lead, pesticides, motor oil, other industrial waste products
- infants and toddlers at highest risk of exposure due to hand-mouth behaviours
- effects dependent on contaminant: leukemia, kidney damage, liver toxicity, neuromuscular blockade, developmental damage to the brain and nervous system, skin rash, eye irritation, headache, nausea, fatigue

Particulate Matter Air Pollution and Cardiovascular Disease: An Update to the Scientific Statement from the American Heart Association
Circulation 2010;121(21):2331-2378
A scientific statement by the American Heart Association in 2004 reported that exposure to particulate matter air pollution contributes to cardiovascular morbidity and mortality. An updated American Heart Association statement in 2010 confirmed a causal relationship between particulate matter exposure and cardiovascular morbidity and mortality. The statement reported that such an exposure over several hr to wk may trigger cardiovascular disease-related mortality and non-fatal events, whereas longer exposures over several yr may further increase cardiovascular mortality risk and reduce life expectancy within highly-exposed populations by several mo to yr.

The Walkerton Tragedy
In May 2000, the drinking water system in the town of Walkerton, ON, became contaminated with *Escherichia coli* O157:H7 and *Campylobacter jejuni*. Over 2300 individuals became ill; 27 people developed hemolytic uremic syndrome and 7 individuals died in the outbreak
Source: Ministry of the Attorney General. Report of the Walkerton inquiry. Ontario, 2002

Water Fluoridation
Water fluoridation, and the resulting decrease in dental caries and reduction in health inequities, is one of the greatest public health achievements of the 20th century. At the recommended concentration of 0.7 mg/L, fluoride reduces cavities by 18-40%. Small but vocal groups opposed to fluoridation have claimed that fluoride intake is not easily controlled, and that children may be more susceptible to health problems. These claims have been widely debunked but still persist, and have led some communities to opt not to fluoridate their water, resulting in increased dental caries (e.g. Calgary). Fluoride concentrations in municipal water should be 0.7 ppm

Food

Biological Hazards

Table 12. Comparison of Select Biological Contaminants of Food and Effects on Human Health

	Source	Effects
Salmonella	Raw eggs, poultry, meat	GI symptoms
Campylobacter	Raw poultry, raw milk	Joint pain, GI symptoms
Escherichia coli	Various including meat, sprouts Primarily undercooked hamburger meat	Watery or bloody diarrhea Hemolytic uremic syndrome (especially children)
Listeria monocytogenes	Unpasteurized cheeses, prepared salads, cold cuts	Listeriosis: nausea, vomiting, fever, headache, rarely meningitis or encephalitis
Clostridium botulinum	Unpasteurized honey, canned foods	Dizziness, weakness, respiratory failure GI symptoms: thirst, nausea, constipation
Prion (BSE*)	Beef and beef products	Variant Creutzfeldt-Jakob disease

*BSE = bovine spongiform encephalopathy

- other biological food contaminants include:
  - viruses, mould toxins (e.g. aflatoxin has been associated with liver cancer), parasites (e.g. *Toxoplasma gondii*, tapeworm), paralytic shellfish poisoning (rare), genetically modified organisms (controversial as to health risks/benefits)

Chemical Hazards

- many persistent organic pollutants are fat-soluble and undergo bioamplification
- drugs (e.g. antibiotics, hormones)
- inadequately prepared herbal medications
- food additives and preservatives
  - nitrites highest in cured meats; can be converted to carcinogenic nitrosamines
  - sulphites commonly used as preservatives; associated with sulphite allergy (hives, nausea, shock)
- pesticide residues
  - older pesticides (e.g. DDT) have considerable human health effects
- polychlorinated biphenyls (PCBs)
  - effects (severe acne, numbness, muscle spasm, bronchitis) much more likely to be seen in occupationally-exposed individuals than in the general population
- dioxins and furans
  - levels highest in fish and marine mammals, also present in breast milk
  - can cause immunosuppression, liver disease, respiratory disease

Examples of Simple Interventions to Reduce Environmental Exposures and Risk of Disease

- sunscreen to prevent sunburns and UV-related damage
- ear plugs to prevent damage from high intensity sound waves

Organic Foods

- Foods designated as "organic" in Canada must conform to the Organic Products Regulations enforced by the Canadian Food Inspection Agency
- Organic foods are not free of synthetic pesticide residues but typically contain smaller amounts compared to conventionally grown foods
- Currently, there has not been strong evidence to suggest that eating organic foods is safer or more nutritious compared to eating conventionally grown food

Sources: Organic foods. Ann Intern Med 2012;157:348-366. Health Canada. Pesticides and food, 2011. UpToDate. Organic foods and children, 2009

Environmental Racism

- defined as the deliberate and disproportionate development of environmental hazards and toxic facilities near to communities of colour and/or lower income communities
- furthermore, historic and present-day colonialist and racist practices contribute to the marginalization of these communities, resulting in a diminished organizational capacity and political power to advocate against the placement and impacts of these environmental hazards
- exposure to these environmental hazards therefore undergird to poorer health outcomes and marginalization already faced by affected individuals and communities
- examples of environmental racism in Canada are ubiquitous against Indigenous communities and communities of colour. Present-day examples include: the placement of oil and gas industries (e.g. the Trans-Mountain pipeline across Indigenous lands); a lack of access to potable water, as seen in communities such as Attawapiskat, Ontario; and other environmental hazards, with two specific examples provided below

Grassy Narrows, Ontario

- a reserve in northwest Ontario, which came to public attention in the 1970s when many of its residents began to develop symptoms of mercury poisoning, including severe neurotoxicity
- the source of contamination was attributed to an upstream paper mill dumping tonnes of untreated mercury into the water over a period of several years
- a loss of natural resources and environmental stewardship had a devastating pervasive impact on the community:
  - the decimation of two major sources of employment in the area (fishing and working as guides)
  - contaminating local food and water supplies
  - leaving the community with limited resources to manage the short- and long-term effects of mercury poisoning

- despite ongoing protest, agreement from the federal government to build a mercury treatment facility was not reached until 2020, approximately 50 years following the initial contamination of Grassy Narrows. At time of writing, construction of such a facility had yet to begin
- despite the federal government's promise to eliminate drinking water advisories on reserves, 61 remain in effect as of February 2020, many in communities that are not even isolated
- oil sands, hydroelectric, diamond mines, and many other projects have negatively impacted Indigenous territories across Canada. Indigenous peoples have reaped very little of the economic benefits from these activities
- the remote geographic location of many Indigenous communities, in conjunction with complex jurisdictional issues, lead to debate over who is responsible for the health of these communities; this often leaves communities with delayed and inadequate responses to community needs
- Canada's adoption of the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP) will help rectify some of these detrimental activities on our environment and Indigenous peoples

Africville, Nova Scotia

- Halifax was founded in 1749
- African people, many of whom were descendants of slaves in Jamaica, dug out roads and built much of the city
- the early Black community lived a few kilometres north of the city in a community established on the Bedford Basin in Halifax, an area that became Africville
- the proximity to the waterfront for fishing, prospects for wage labour in the city, and establishment of structures including a post office, school, and church created a tight-knit Black community which, at one point, housed over 400 individuals and families
- facilities deemed otherwise unfit for surrounding areas were established in Africville by city council and businesses, including an oil plant, tar factory, prison, hospital for infectious diseases, and open garbage dump, with raw sewage and waste products emptying directly into the water supply
- the community was denied resources available to predominantly White neighbouring areas, despite being within the municipal jurisdiction, including garbage collection, law enforcement, paved roads, and appropriate water treatment
- in 1957, the city expropriated the land for industrial use and forced the relocation of residents, many of whom into public housing
- a settlement was reached between some former Africville residents and the City of Halifax in 2010, although an application for a class-action lawsuit submitted to the Supreme Court of Halifax was overturned in 2018
- on 24 February 2010, Halifax Regional Municipality Mayor Peter Kelly apologized for the destruction of Africville

Occupational Health

- a field involved in the prevention of illness or injury and the promotion of health in the work environment
- services encompass recognizing and controlling exposure to hazards (primary prevention), occupational health surveillance and screening (secondary prevention), and treatment and rehabilitation (tertiary prevention)
- occupational disease often looks clinically the same as non-occupational disease and, without a thorough occupational health history, may go unrecognized as distinct

Taking an Occupational Health History

- current and previous duties at place of employment
- exposures
  - identification: screen for chemical, metal, dust, biological, and physical hazards as well as psychological stressors - workers may bring safety data sheets (formerly MSDSs) that provide information about hazards of exposure
  - assessment: duration, concentration, route, exposure controls (e.g. ventilation and other environmental controls, personal protective equipment)
- temporal relationship: changes in symptoms in relationship to work environment, latency between first exposure and current symptoms
- presence of similar symptoms in co-workers
- non-work exposures to hazardous agents: home, neighbourhood, hobbies
- additional assessment may be required (e.g. chest radiography, ultrasound, PFT)

Taking an Occupational Health Hx WHACS

What do you do?
How do you do it?
Are you concerned about any particular exposures on or off the job?
Co-workers or others with similar problems?
Satisfied with your job?

Source: J Occup Environ Med 1998;40:680-684

Occupational Health Statistics

- In 2018, 1027 workers died of work-related causes in Canada
- The average time-loss injury rate between 2014-2018 ranged across Canadian provinces and territories from 1.02 to 2.89 per 100 workers
- Provincial and territorial compensation boards do not cover all workplaces (e.g. most agricultural workers)
- Compensation board insurance coverage ranges across provinces and territories from 74-99% of the workforce

Source: 2020 Report on Work Fatality and Injury Rates in Canada

Information about worker's compensation at: https://awcbc.org/en/

Occupational Hazards

Table 13. Occupational Hazards

Physical	Chemical	Biological	Psychosocial	Ergonomic / Safety
Noise (e.g. hearing loss) Temperature Heat cramps, heat exhaustion, heat stroke Hypothermia, frostbite Air pressure (e.g. barotrauma, decompression sickness) Radiation Non-ionizing: visible light, infrared Ionizing: UV, x-rays, γ rays Vibration-related disorders (e.g. secondary Raynaud's, whole body vibration)	Organic solvents (e.g. benzene, methyl alcohol; most toxic is carbon tetrachloride) Mineral dusts (e.g. silica leads to silicosis and predisposition to TB, asbestos leads to diffuse fibrosis and mesothelioma, coal leads to pneumoconiosis) Heavy metals (e.g. nickel, cadmium, mercury, lead) Gases (e.g. halogen gases, sulphur dioxide, carbon monoxide, nitrogen oxides) Second-hand smoke (causal factor for lung cancer, lung disease, heart disease, asthma exacerbations; may be linked to miscarriage) Skin diseases (major portion of compensations, e.g. contact dermatitis, occupational acne, pigmentation disorders)	Exposure to bacteria, viruses, fungi, protozoa, Rickettsia Exposure to biological proteins, endotoxins, enzymes, animal excreta Blood should be considered a potentially toxic substance due to blood-borne infectious diseases (e.g. HIV, hepatitis B) Consider exposure to disease in endemic countries, travellers from endemic countries, or recent travel history in the setting of acute onset of symptoms (e.g. malaria, SARS, TB)	Workload stressors Responsibility Fear of job loss Geographical isolation Shift work Bullying Harassment (sexual/non-sexual) Incurs high cost from absenteeism, poor productivity, mental illness (e.g. post-traumatic stress disorder) Workplace violence (involving staff, clients, the general public)	Workload stressors Responsibility Fear of job loss Geographical isolation Shift work Bullying Harassment (sexual/non-sexual) Incurs high cost from absenteeism, poor productivity, mental illness (e.g. post-traumatic stress disorder) Workplace violence (involving staff, clients, the general public)

Workplace Legislation

- universal across Canada for corporate responsibility in the workplace: reasonable precautions to ensure a safe workplace, application of Workplace Hazardous Materials Information System (WHMIS), existence of joint health and safety committees in the workplace with representatives from workers and management
- jurisdiction in Canada is provincial (90% of Canadian workers), except for 16 federally-regulated industries (e.g. airports, banks, highway transport) under the *Canada Labour Code*
- Ontario's *Occupational Health and Safety Act*
  - sets out rights of workers and duties of employers, procedures for workplace hazards, and law enforcement
  - workers have the right to:
    - know (e.g. be trained and have information about workplace hazards)
    - participate (e.g. have representatives on joint health and safety committees)
    - refuse work (e.g. workers can decline tasks they feel are overly dangerous)
      - note: for some occupations, this right is restricted if, for example, danger/risk is normal part of work or refusal would endanger others (e.g. police, firefighters, some health care workers)
    - stop work (e.g. 'certified' workers can halt work they feel is dangerous to other workers)
  - enforced by Ministry of Labour via inspectors
- *Health Protection and Promotion Act* (HPPA) (Ontario)
- Medical Officer of Health has right to investigate and manage health hazards where workplace exposures may impact non-workers (e.g. community members living close to the work site)

Workplace Health Promotion

- a strategy for addressing the health and well-being of workers in the workplace, not legislated
- may include education, event planning, information campaigns, workplace supports to promote personal worker health and a healthy workforce

Workplace Primary Prevention

- proactive efforts to reduce workplace illness or injury
- achieved through anticipating, recognizing, evaluating, and controlling workplace hazards
- hierarchy of controls (see Figure 18) is followed to minimize exposure – elimination/substitution of hazards is most superior, followed by isolation (engineering controls), training and behavioural efforts (administrative controls), and lastly personal protective equipment

Occupational Safety And Health Enforcement Tools For Preventing Occupational Diseases And Injuries
Cochrane DB Syst Rev 2013:CD010183
Purpose: To assess the effects of occupational safety and health regulation enforcement tools for preventing occupational diseases and injuries.
Outcome: Inspections decrease injuries in the long term, but not short term, with an unclear magnitude of effect.

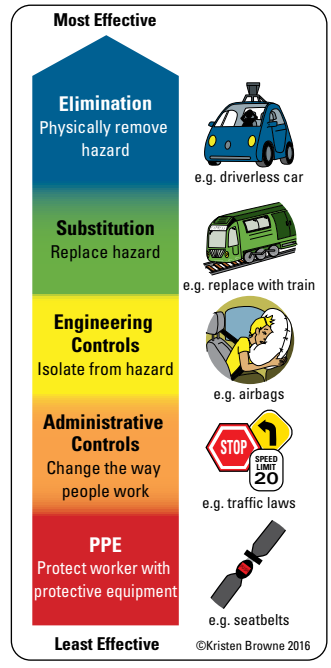

Figure 18. Hierarchy of controls for reduction of occupational exposures
Source: Modified from CDC. 2015. Hierarchy of controls. http://www.cdc.gov/niosh/topics/hierarchy/

***Ontario's Workplace Safety and Insurance Act* (each province will have their own corresponding legislation)**
- Establishes Workplace Safety and Insurance Board (WSIB), an autonomous government agency that oversees workplace safety training and administers insurance for workers and employers
- WSIB decides benefits for workers, which may include reimbursement for:
  - Loss of earned income
    - Non-economic loss (e.g. physical, functional, or psychological loss extending beyond the workplace)
    - Loss of retirement income
    - Health care expenses (e.g. first-aid, medical treatment)
    - Survivor benefits (e.g. dependents and spouses can receive benefits)
- Employers pay for costs (e.g. no government funding)
- No-fault insurance (e.g. worker has no right to sue the employer) in return for guaranteed compensation for accepted claims
- Negligence is not considered a factor
- Physicians are required to provide the WSIB with information about a worker's health without a medical waiver once a claim is made

For more information: http://www.wsib.on.ca/en/community/WSIB

Workplace Secondary Prevention

- for workers who are exposed to workplace hazards, goal is to identify earliest signs of overexposure or disease through medical surveillance (periodic examinations to identify early changes in a single worker or multiple workers). Some examples include:
  - whole blood lead testing to identify effectiveness of controls, need to remove workers from exposure
  - PFT for asthma (e.g. occupational dust exposure)
  - audiograms for hearing loss (e.g. occupational noise exposure)

Workplace Tertiary Prevention

- treatment of the disease or injury to facilitate safe and timely return to the workforce
- may require rehabilitation, retraining, change in job duties, and/or workers' compensation (WSIB)
- often also involves accommodating the workplace for a worker who has a non-occupational injury or illness, with routine reassessments of the fit between the worker and their duties - work that is considered safety-sensitive may be restricted for workers with ailments that could impede their ability to work safely, or a worker may be medically determined to have limitations with what they can reasonably do at work
- advise relevant authorities if necessary (e.g. report notifiable diseases to public health, conditions impeding driving to Ministry of Transportation)

Appendix – Mandatory Reporting

Reportable Diseases

As an essential part of the public health system, physicians in Canada are required by provincial law to report certain diseases to public health. Physician reporting is also outlined by provincial physician licensing Colleges (e.g. College of Physicians and Surgeons of Ontario (CPSO)). Failure to report can result in suspension of a license to practice.

The reasons that reporting is mandatory include:
1. to identify and control an outbreak
2. to prevent spread if the disease presents a significant threat to individuals or a subset of the population (e.g. Lassa Fever)
3. if the disease is preventable with immunization (e.g. polio, diphtheria, congenital rubella)
4. if infected individuals require education, treatment, and/or partner notification (e.g. gonorrhea, TB)
5. surveillance (to monitor disease trends over time)

Diseases of Public Health Significance

Diseases marked with * (and Influenza in institutions) should be reported immediately to the Medical Officer of Health by either telephone or fax. Other diseases can be reported the next working day by fax, phone, or mail. Each province/territory has a similar legislation.

Acquired Immunodeficiency Syndrome (AIDS)
Acute flaccid paralysis <15 yr
Amoebiasis
Anthrax*

Botulism*
Brucellosis*
Blastomycosis

Campylobacter enteritis
Carbapenemase-Producing Enterobacteriaceae (CPE)
Chancroid
Chickenpox (Varicella)
Chlamydia trachomatis infections
Cholera*
*Clostridium difficile** associated disease (CDAD) outbreaks in public hospitals
Coronavirus novel including SARS, MERS, and COVID-19*
Creutzfeldt-Jakob Disease, all types*
Cryptosporidiosis*
Cyclosporiasis*
Diphtheria*

Echinococcus multilocularis infection

Encephalitis, including:
1. Primary, viral
2. Post-infectious
3. Vaccine-related
4. Subacute sclerosing panencephalitis
5. Unspecified

Food poisoning, all causes

Gastroenteritis, institutional outbreaks and in public hospitals*
Giardiasis, except asymptomatic cases*
Gonorrhea

Haemophilus influenzae b disease, all types*
Hantavirus pulmonary syndrome*
Hemorrhagic fevers*, including:
1. Ebola virus disease*
2. Marburg virus disease*
3. Other viral causes*
Hepatitis, viral*:
1. Hepatitis A*
2. Hepatitis B
3. Hepatitis C

Influenza (Note: Influenza in institutions*)

Lassa Fever*
Legionellosis
Leprosy
Listeriosis
Lyme Disease

Measles*
Meningitis, acute*:
1. Bacterial*
2. Viral
3. Other
Meningococcal disease, invasive*
Mumps

Ophthalmia neonatorum

Paralytic shellfish poisoning
Paratyphoid fever
Pertussis (whooping cough)
Plague*
Pneumococcal disease, invasive
Poliomyelitis, acute*
Psittacosis/Ornithosis

Q Fever*

Rabies*
Respiratory infection outbreaks in institutions and public hospitals*
Rubella*
Rubella, congenital syndrome

Salmonellosis
Shigellosis*
Smallpox*
Syphilis

Tetanus
Trichinosis
Tuberculosis, active and latent Tularemia
Typhoid Fever

Verotoxin-producing *E. coli* infection* indicator conditions, including Hemolytic Uremic Syndrome (HUS)*

West Nile Virus illness, including:
1. West Nile fever
2. West Nile neurological manifestations

Yersiniosis

Other Reportable Conditions

- in addition to reporting diseases, physicians have a legal responsibility to report certain conditions. The list below highlights some reportable conditions for Ontario, but is not exhaustive. See your jurisdiction's regulatory body for the full list

Live Births, Stillbirths, and Deaths – to the Registrar General or Coroner*

- all live and stillbirths must be reported within 2 business days
- a physician with sufficient familiarity of a patient's illness or who was in attendance of a deceased patient's last illness must complete and sign the medical certificate of death
- physicians must contact a coroner or the police if patient is suspected to have deceased from violence, misadventure, negligence, misconduct or malpractice, or any cause other than disease; by unfair means; during pregnancy or postpartum from circumstances reasonably attributed to the pregnancy; suddenly and unexpectedly; from an illness not treated by a legally qualified medical practitioner; or under circumstances that may require investigation*
- physicians must report all medically assisted deaths to the coroner*

Child Abuse – to Local Children's Aid Society (CAS)

- all child abuse and neglect where reasonable grounds to suspect exist (including physical harm, emotional harm, sexual harm, and neglect)
- ongoing duty to report: if additional reasonable grounds are suspected, a further report to CAS is necessary

Gunshots Wounds – to Local Police Service

- all patients with gunshot or stab wounds should be reported as soon as is practical
- self-inflicted knife wounds are not reportable

Abuse of Long-Term Care or Retirement Home Residents – to the Registrar of the Retirement Homes Regulatory Authority or Long-Term Care Home Director

- any resident suspected of being subject to or at risk of improper or incompetent treatment or care, abuse or neglect, or unlawful conduct including financial abuse must be reported immediately

Unfit to Drive – to Provincial Ministry of Transportation

- all patients with a medical condition (e.g. dementia, untreated epilepsy, ophthalmological) that may impede their driving ability
- if a physician does not report and the driver gets into an accident, the physician may be held liable

Unfit to Fly – to Federal Ministry of Transportation

- all patients believed to be flight crew members or air traffic controller with a medical or optometric condition that is likely to constitute a hazard to aviation safety

Landmark Public Health and Preventive Medicine Trials

Trial Name	Reference	Clinical Trial Details
Mammography		
Swedish Two-County Trial	Radiology 2011;260(3):658-63	**Title**: Swedish Two-County Trial: Impact of Mammographic Screening On Breast Cancer Mortality During 3 Decades **Purpose**: Evaluate the long-term effect of mammographic screening on breast cancer mortality. **Methods**: 133065 women aged 40-74 yr were randomly assigned to either a group invited for mammographic screening or a control group. A negative binomial regression analyzed mortality. **Results**: At 29 yr of follow-up, a large significant reduction in breast cancer mortality was found in the group invited for mammographic screening compared to the control group (relative risk = 0.69; 95% CI: 0.56 to 0.84). **Conclusions**: Invitation to mammographic screening leads to a large significant decrease in breast cancer-related mortality.
Vaccination		
VAXICOL	J Am Geriatr Soc 2009;57(9):1580-6	**Title**: Effect of Influenza Vaccination of Nursing Home Staff on Mortality of Residents: A Cluster-Randomized Trial **Purpose**: Evaluate the impact of influenza vaccination among staff on all-cause mortality in nursing home residents. **Methods**: 40 nursing homes matched in pairs were randomly assigned to the vaccination arm or no-vaccination control arm. The vaccination arm involved a vaccine promotion campaign and administration program for staff. **Results**: Vaccination rates among staff in the vaccination arm were 69.9% compared to 31.8% in the no-vaccination arm. A strong correlation between staff vaccination coverage and all-cause mortality of the residents was found (correlation coefficient = -0.42, P=0.007). **Conclusions**: The results support staff of nursing homes being vaccinated against influenza to reduce all-cause mortality of residents.

Peter Nakhla and **Kyle Seigel,** EBM editors
Dr. Samir Gupta, Dr. Ambrose Lau, and **Dr. Christopher Li,** staff editors

Acronyms

A-a	alveolar-arterial
A-aDO_2	alveolar-arterial oxygen diffusion gradient
ABG	arterial blood gas
ACEI	angiotensin converting enzyme inhibitor
AECOPD	acute exacerbation of COPD
AHI	apnea hypopnea index
AIP	acute interstitial pneumonia
ALI	acute lung injury
ALS	amyotrophic lateral sclerosis
ANA	antinuclear antibody
ANCA	anti-neutrophil cytoplasmic antibody
Anti-CCP	anti-cyclic citrullinated peptide antibody
aPTT	activated partial thromboplastin time
ARDS	acute respiratory distress syndrome
ASA	acetylsalicylic acid (Aspirin®)
AV	arteriovenous
BG	blood glucose
BiPAP	bilevel positive airway pressure
BSA	body surface area
CA	cancer
CCB	calcium channel blocker
CF	cystic fibrosis
CI	cardiac index
CO	cardiac output
COP	cryptogenic organizing pneumonia
CPAP	continuous positive airway pressure
CSA	central sleep apnea
CVP	central venous pressure
CWP	coal worker's pneumoconiosis
DIC	disseminated intravascular coagulation
DLCO	carbon monoxide diffusing capacity of lung
DOAC	direct oral anticoagulant
DPD	distal phalangeal finger depth
EBUS	endobronchial ultrasound
EGDT	early goal-directed therapy
ERV	expiratory reserve volume
FEF	forced expiratory flow rate
FEV_1	forced expiratory volume in 1 second
FiO_2	fraction of oxygen in inspired air
FRC	functional residual capacity
FVC	forced vital capacity
GBM	glomerular basement membrane
GERD	gastroesophageal reflux disease
H/A	headache
HPA	hypothalamic-pituitary axis
IC	inspiratory capacity
ICS	inhaled corticosteroid
ILD	interstitial lung disease
IPD	interphalangeal depth
IPF	idiopathic pulmonary fibrosis
LABA	long-acting β-agonist
LAMA	long-acting muscarinic antagonist
LMWH	low molecular weight heparin
LTRA	leukotriene receptor antagonist
LA	left atrium
LV	left ventricle
LVEDP	left ventricular end diastolic pressure
MEP	maximal expiratory pressure
MIP	maximal inspiratory pressure
MDI	metered dose inhaler
MSK	musculoskeletal
NSIP	non-specific interstitial pneumonia
N/V	nausea/vomiting
OSA	obstructive sleep apnea
PA	posteroanterior
$PaCO_2$	arterial partial pressure of carbon dioxide
PaO_2	arterial partial pressure of oxygen
PAO_2	alveolar partial pressure of oxygen
PAP	positive airway pressure
P_{atm}	atmospheric pressure
PCWP	pulmonary capillary wedge pressure
PE	pulmonary embolism
PEEP	positive end expiratory pressure
PEF	peak expiratory flow
PFT	pulmonary function tests
PiO_2	inspired oxygen tension
PP	pulse pressure
PPI	proton pump inhibitor
PTT	partial thromboplastin time
RA	rheumatoid arthritis
RAD	right axis deviation
RAP	right atrial pressure
RF	rheumatoid factor
RV	residual volume
RVEDV	right ventricular end diastolic volume
RVH	right ventricular hypertrophy
SABA	short-acting β2-agonists
SIRS	systemic inflammatory response syndrome
SOFA	sepsis-related organ failure assessment score
qSOFA	quick sepsis-related organ failure assessment score
SV	stroke volume
SVC	superior vena cava
SVRI	systemic vascular resistance index
TLC	total lung capacity
UC	ulcerative colitis
UIP	usual interstitial pneumonia
URTI	upper respiratory tract infection
V/Q	ventilation-to-perfusion
VC	vital capacity
VTE	venous thromboembolism
VT	tidal volume

Approach to the Respiratory Patient

Basic Anatomy Review

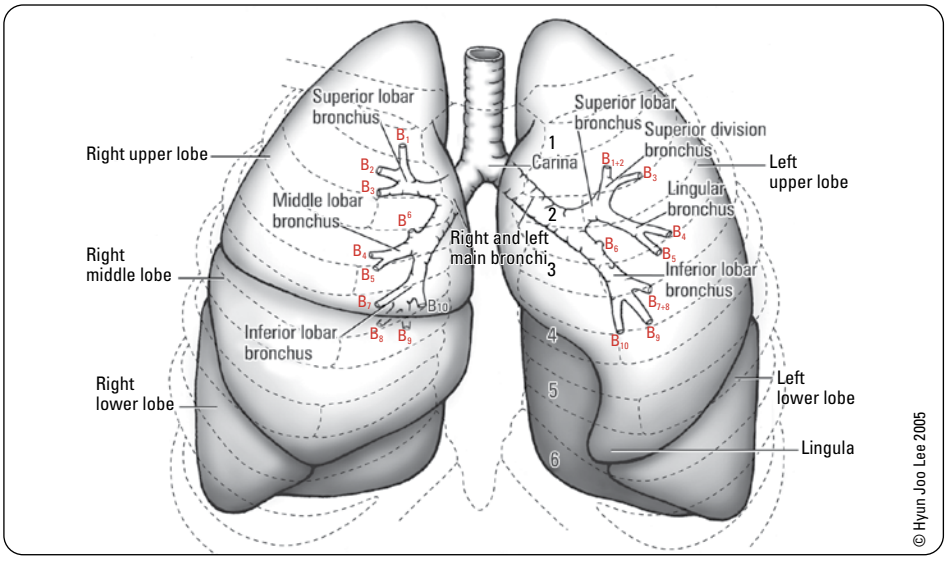

Figure 1. Lung lobes and bronchi

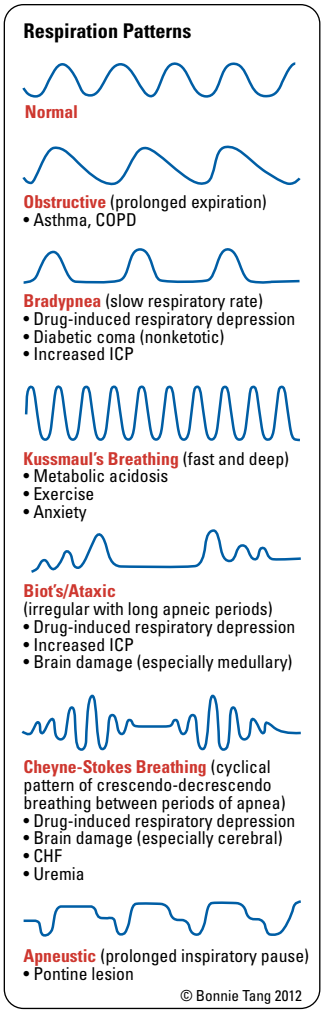

Figure 2. Respiration patterns in normal and disease states

Differential Diagnoses of Common Presentations

Table 1. Differential Diagnosis of Dyspnea

ACUTE DYSPNEA (MINUTES-DAYS)

Cardiac
- Acute Coronary Syndrome
- Acute Decompensated Heart Failure
- Acute myocardial infarction
- CHF exacerbation
- Cardiac tamponade
- Arrhythmia

Pulmonary

Upper airway obstruction (anaphylaxis, aspiration, croup, EBV)
- Airway disease (asthma, COPD exacerbation, bronchitis)
- Parenchymal lung disease (ARDS, pneumonia)
- Pulmonary vascular disease (PE, vasculitis)
- Pleural disease (pneumothorax, tension pneumothorax, pleural effusion)

Neurologic/Psychogenic
- Respiratory control (metabolic acidosis, trauma)
- Anxiety
- Panic attack (Post Traumatic Stress Disorder)

CHRONIC DYSPNEA (+4 WEEKS)

Cardiac
- Valvular heart disease
- Myocardial dysfunction (decreased CO)

Pulmonary
- Airway disease (asthma, COPD)
- Parenchymal lung disease (interstitial disease)
- Pulmonary vascular disease (pulmonary HTN, vasculitis)
- Pleural disease (effusion)

Metabolic
- Medication
- Severe anemia
- Hyperthyroidism

Neuromuscular and chest wall disorders
- Deconditioning, obesity, pregnancy, neuromuscular disease

Psychogenic
- Anxiety

Table 2. Differential Diagnosis of Chest Pain

NONPLEURITIC	PLEURITIC
Pulmonary	**Pulmonary**
Pneumonia	Pneumonia
PE	PE
Neoplasm	Neoplasm
Cardiac	Pneumothorax
MI	Pleurisy
Myocarditis/pericarditis	Hemothorax
Deconditioning	TB
Esophageal	Empyema
GERD	**Cardiac**
Spasm	Pericarditis
Esophagitis	Dressler's syndrome
Ulceration	**GI**
Achalasia	Subphrenic abscess
Neoplasm	**MSK**
Esophageal rupture	Costochondritis
Mediastinal	Fractured rib/flail chest
Lymphoma	Myositis
Thymoma	Herpes zoster
Subdiaphragmatic	**Psychogenic**
Peptic ulcer disease	Anxiety
Gastritis	Panic attack/disorder
Biliary colic	
Pancreatitis	
Vascular	
Aortic aneurysm	
Aortic dissection	
Aortic injury/rupture	
MSK	
Costochondritis	
Skin	
Breast	
Ribs	
Rheumatic disease	
Metabolic	
Anemia	
Hyperthyroidism	
Psych	
Anxiety	
Panic attack/disorder	
Miscellaneous	
Pregnancy	
Weight gain	

See Cardiology and Cardiac Surgery C5 and Emergency Medicine ER21

Table 3. Differential Diagnosis of Hemoptysis

AIRWAY DISEASE

Acute or chronic bronchitis*
Bronchiectasis
Bronchogenic CA
Bronchial carcinoid tumour
CF

Parenchymal Disease
- Pneumonia
- TB
- Lung abscess
- Fungal infection
- Primary lung cancer
- Pulmonary metastasis

Vascular Disease
- PE
- Elevated pulmonary venous pressure:
  - Left ventricular dysfunction/failure
  - Mitral stenosis
- Vascular malformation
- Vasculitis:
- ANCA related vasculitides
  - Goodpasture's syndrome
  - Idiopathic pulmonary hemosiderosis

Miscellaneous
- Iatrogenic (lung biopsy, airway ablation procedures)
- Impaired coagulation
- Pulmonary endometriosis – catamenial hemoptysis
- Trauma
- Foreign body

*Most common cause of hemoptysis

Table 4. Differential Diagnosis of Cough

COUGH DDx

Airway Irritants

Inhaled smoke, dusts, fumes

Postnasal drip (upper airway cough syndrome)

Aspiration
- **Gastric contents (GERD)***
- Laryngopharyngeal reflux
- Oral secretions
- Foreign body

Airway Disease
- **URTI including postnasal drip and sinusitis***
- Acute or chronic bronchitis
- Bronchiectasis
- Neoplasm
- External compression by node or mass lesion
- **Asthma***
- COPD

Parenchymal Disease
- Pneumonia
- Lung abscess
- Interstitial lung disease
- **PE**
- **CHF**
- **Drug-induced (e.g. ACEI)**
- **Smoking**

*"Big Three" causes of chronic cough

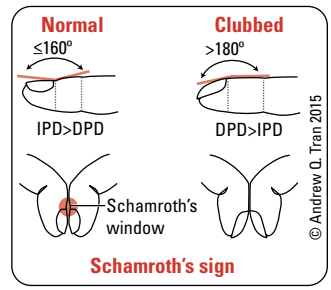

Figure 3. Signs of nail clubbing

Signs of Respiratory Distress
- Tachypnea
- Central/peripheral cyanosis
- Tachycardia
- Inability to speak
- Nasal flaring
- Tracheal tug
- Intercostal indrawing
- Tripoding
- Paradoxical breathing

Common Causes of Clubbing
- Pulmonary: lung CA, bronchiectasis, pulmonary fibrosis, abscess, CF, TB, empyema, A-V fistula/malformation (NOT COPD)
- Cardiac: cyanotic congenital heart disease, endocarditis
- GI: inflammatory bowel disease, celiac, cirrhosis, neoplasm
- Endocrine: Graves' disease
- Other: other malignancy, primary hypertrophic osteoarthropathy

Clubbing is not seen in COPD – if present, think malignancy

Hemoptysis
- Most common cause is bronchitis
- 90% of massive hemoptysis is from the bronchial arteries
- Definitions for hemoptysis vary, often defined as "massive" if >600 mL/24 h or bleeding rate of >100 mL/h

Most Common Causes of Chronic Cough in the Non-smoking Patient (Cough >3 mo with Normal CXR)
- GERD
- Asthma
- Postnasal drip
- ACEI

Adapted from: Weinberger SE. Principles of pulmonary medicine, 5th ed. 2008. With permission from Elsevier

Pulmonary Function Tests

- useful in differentiating the pattern of lung disease (obstructive vs. restrictive)
- assess lung volumes, flow rates, and diffusion capacity
- note: normal values for FEV_1 are approximately ±20% of the predicted values (for age, sex, and height); ethnicity may affect predicted values

Table 5. Comparison of Lung Flow and Volume Parameters in Lung Disease

	Obstructive	Restrictive
	Decreased flow rates (most marked during expiration)	Decreased lung compliance
	Air trapping (increased RV/TLC)	Decreased lung volumes
	Hyperinflation (increased TLC)	
DDx	Asthma, COPD, CF, bronchiolitis, bronchiectasis*	ILD, pleural disease, neuromuscular disease, chest wall disease
FEV_1/FVC	Reduced	Increased or normal
TLC	Elevated or normal	Reduced
RV	Elevated or normal	Reduced, normal or increased
RV/TLC	Elevated or normal	Normal or increased (neuromuscular disease may have increased RV/TLC ratio)
DLCO	Normal or reduced depending on disease state	Reduced or normal depending on whether parenchymal or extraparenchymal restriction is present

*Bronchiectasis can be obstructive or mixed

Table 6. Common Respirology Procedures

Technique	Purpose	Description
Plethysmography ("body box")	Measure FRC	After a normal expiration, the patient inhales against a closed mouthpiece Resultant changes in the volume and pressure of the plethysmograph are used to calculate the volume of gas in the thorax Useful for patients with air trapping
He Dilution	Measure FRC	A patient breathes from a closed circuit containing a known concentration and volume of helium Since the amount of helium remains constant, FRC is determined based on the final concentration of the helium in the closed system Only includes airspaces that communicate with the bronchial tree – may underestimate volumes in patients with bullous disease
Bronchoscopy	Diagnosis and therapy	A flexible or rigid bronchoscope is used for visualization of a patient's airways allows for: Bronchial and broncho-alveolar lavage (washings) for culture, cell count analysis, and cytology Endobronchial or transbronchial tissue biopsies Removal of secretions/foreign bodies/blood Laser resections Airway stenting Mediastinal lymph nodes can also be sampled using a special bronchoscope equipped with an U/S probe (EBUS)

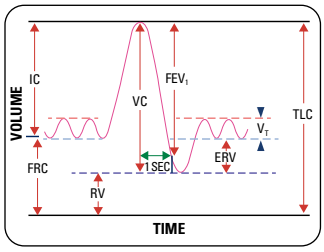

Figure 4A. Lung volumes and capacities

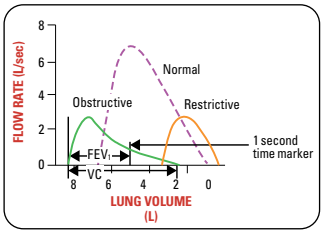

Figure 4B. Expiratory flow volume curves

Adapted with permission from Elsevier. Weinberger SE. Principles of pulmonary medicine, 5th ed. 2008

Lung Volumes

ERV – Expiratory Reserve Volume
FEF – Forced Expiratory Flow Rate
FEV_1 – Forced Expiratory Volume (in one second)
FRC – Functional Residual Capacity
IC – Inspiratory Capacity
RV – Residual Volume
TLC – Total Lung Capacity
VC – Vital Capacity
VT – Tidal Volume

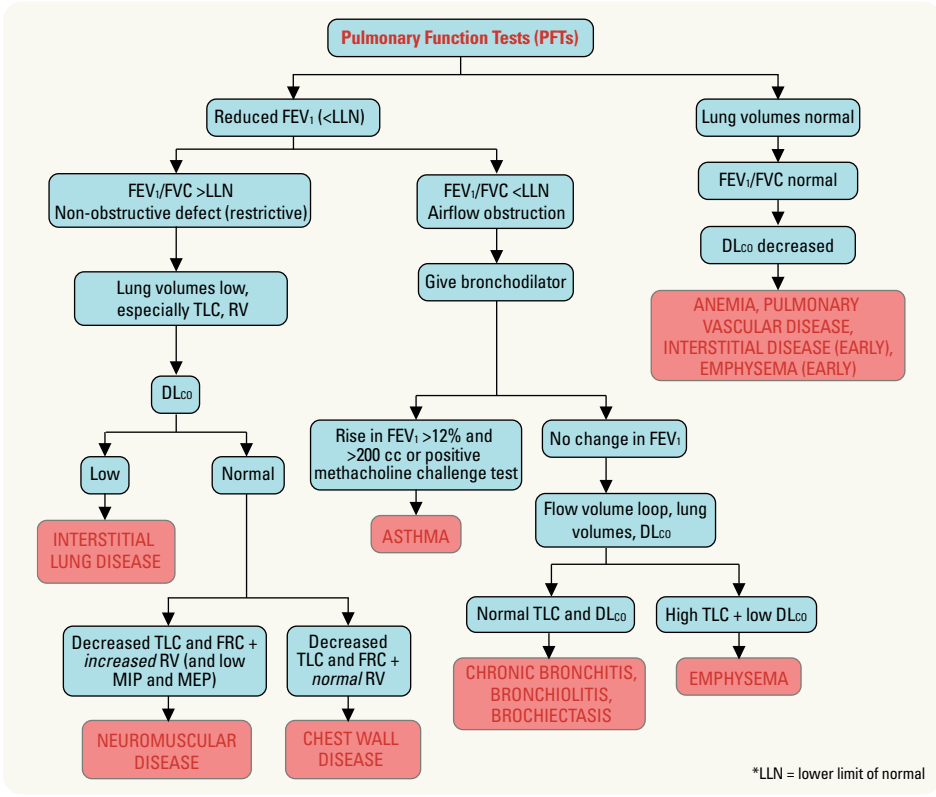

Figure 5. Interpreting PFTs

Chest X-Rays

- see Medical Imaging, MI4

Table 7. CXR Patterns and Differential Diagnosis

Pattern	Signs	Common DDx
Consolidation ("Airspace disease")	Air bronchogram Silhouette sign Less visible blood vessels	Acute: water (PE), pus (pneumonia), blood (hemorrhage) Chronic: neoplasm (lymphoma, bronchioloalveolar carcinoma), inflammatory (eosinophilic pneumonia, organizing pneumonia), infection (TB, fungal)
Reticular ("Interstitial disease")	Increased linear markings Fine or ground glass opacities Honeycombing (clustered cystic changes seen in IPF usually, but also in rheumatoid arthritis, asbestosis etc.)	ILD (IPF, collagen vascular disease, asbestos, drugs), hypersensitivity pneumonitis
Nodular	Cavitary vs. non-cavitary	Cavitary: neoplasm (primary – squamous cell carcinoma vs. metastatic cancer), infectious (anaerobic or Gram negative, TB, fungal), inflammatory (RA, sarcoidosis, granulomatosis with polyangiitis (GPA)) Non-cavitary: above + sarcoidosis, Kaposi's sarcoma (in HIV), silicosis, and coal worker's pneumoconiosis

Arterial Blood Gases

- provides information on acid-base and oxygenation status
- see Nephrology, NP17

Approach to Acid-Base Status

1. Is the pH acidemic (pH <7.35), alkalemic (pH >7.45), or normal (pH 7.35-7.45)?
2. What is the primary disturbance?
   metabolic: change in HCO_3^- and pH in same directions
   respiratory: change in HCO_3^- and pH in opposite directions
3. Is there appropriate compensation? (see Table 8, R6)
   metabolic compensation occurs over 2-3 d reflecting altered renal HCO_3^- production and excretion
   respiratory compensation through ventilatory control of $PaCO_2$ occurs immediately
   inadequate compensation may indicate a second acid-base disorder

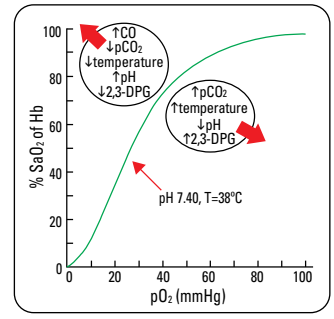

Figure 6. Oxygen-Hb dissociation curve

Table 8. Expected Compensation for Specific Acid-Base Disorders

Disturbance	$PaCO_2$ (mmHg) (normal ~40)	HCO_3^- (mmHg) (normal ~24)
Respiratory Acidosis		
Acute	↑ 10	↑ 1
Chronic	↑ 10	↑ 3
Respiratory Alkalosis		
Acute	↓ 10	↓ 2
Chronic	↓ 10	↓ 5
Metabolic Acidosis	↓ 1	↓ 1
Metabolic Alkalosis	↑ 5-7	↑ 10

4. If the patient has metabolic acidosis, what is the anion gap and osmolar gap?
   - anion gap = $[Na^+]-([Cl^-]+[HCO_3^-])$; normal 5-14 mmol/L
   - osmolar gap = measured osmolarity – calculated osmolarity = measured – $(2[Na^+]$ + glucose + urea); normal ≤10 mmol/L
   - abnormal osmolar gap indicates the presence of alcohols
5. If anion gap is increased, is the change in bicarbonate the same as the change in anion gap?
   - if not, consider a mixed metabolic picture

Table 9. Differential Diagnosis of Respiratory Acidosis

Increased P_aCO_2 secondary to hypoventilation

Respiratory Centre Depression (Decreased RR)	Neuromuscular Disorders (Decreased Vital Capacity)	Lung Disease	Mechanical Hypoventilation (Inadequate Mechanical Ventilation)
Drugs (anesthesia, sedatives, narcotics)	Myasthenia gravis	Chronic: COPD, CF	
Trauma	Guillain-Barré syndrome	Acute: Asthma	
Encephalitis	Botulism	Pulmonary edema	
Stroke	Poliomyelitis	Pneumothorax	
Central apnea	Muscular dystrophies	Pneumonia	
Supplemental O_2 in chronic CO_2 retainers (e.g. COPD)	ALS	ILD (late stage)	
	Myopathies	ARDS	
	Chest wall disease (obesity, kyphoscoliosis)		

Table 10. Differential Diagnosis of Respiratory Alkalosis

Decreased P_aCO_2 secondary to hyperventilation

Systemic Diseases	Respiratory Centre Stimulation	Mechanical Hyperventilation (Excessive Mechanical Ventilation)
Pulmonary disease (pneumonia, edema, PE, interstitial fibrosis)	Drugs (ASA, progesterone, theophylline, catecholamines, psychotropics, nicotine, salicylates)	
Severe anemia	Hepatic failure	
Heart failure	Gram-negative sepsis	
	Pregnancy	
	Anxiety	
	Pain	
	High altitude	

- see Nephrology, NP18 for differential diagnosis of metabolic acidosis and alkalosis

Factors that Shift the Oxygen-Hb Dissociation Curve to the Right

"CADET, face right!"
CO_2
Acid
2,3-DPG
Exercise
Temperature (increased)

Note: 2,3-DPG (2,3-diphosphoglycerate) is now called 2,3-BPG (2,3-biphosphoglycerate)

Acidosis ↔ Hyperkalemia
Alkalosis ↔ Hypokalemia

Note: Mixed acid-base disturbances can still have a "normal" pH

Osmolar Gap = measured osmolarity – calculated osmolarity; for calculated osmolarity think "2 salts and a sticky BUN" (2Na + glucose + urea)

Anion Gap Metabolic Acidosis

MUDPILESCAT
Methanol
Uremia
Diabetic ketoacidosis/starvation ketoacidosis
Phenformin/Paraldehyde
Isoniazid, Iron, Ibuprofen
Lactic acidosis
Ethylene glycol
Salicylates
Cyanide, Carbon dioxide
Alcoholic ketoacidosis
Toluene, Theophylline

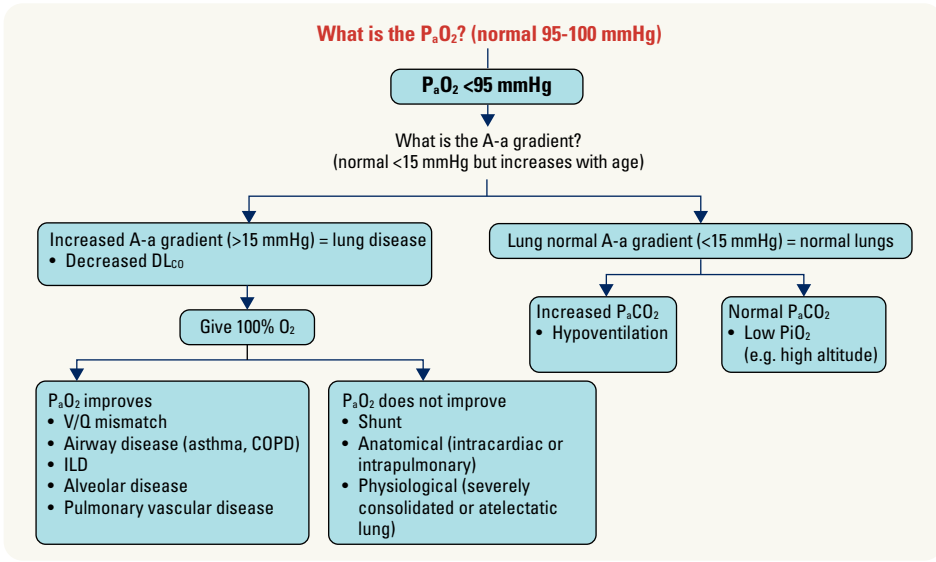

Figure 7. Approach to hypoxemia

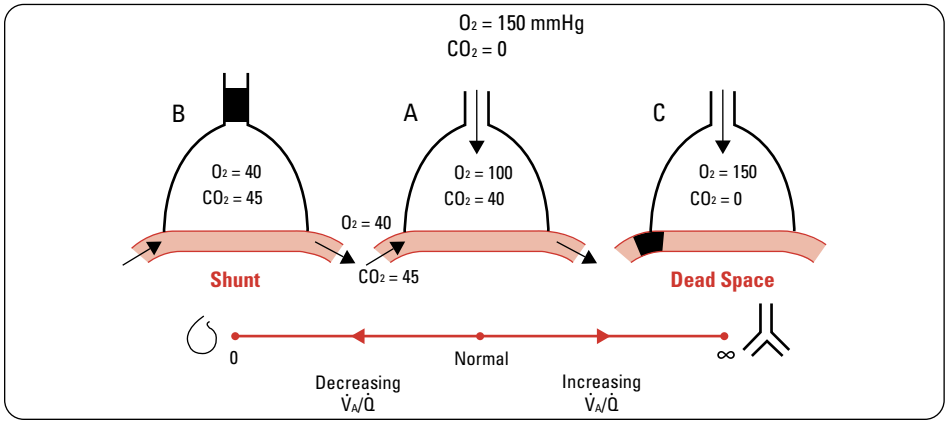

Figure 8. Pathophysiology of V/Q mismatch
Figure adapted from West – Respiratory Physiology: The Essentials. 9th Ed. 2012. Lippincott Williams & Wilkins, Philadelphia, PA.

At Sea Level on Room Air
FiO_2 = 0.21
P_{atm} = 760 mmHg
PH_2O = 47 mmHg
RQ = 0.8
Thus, A-aDO2 gradient on room air
A-aDO_2 = (150 – 1.25 [PaO_2]) – PaO_2
PiO_2 = (FiO_2 x (barometric pressure – PH_2O))

Diffusion Capacity for CO

DLco decreases in:
- Interstitial lung disease
- Pulmonary vascular disease
- Anemia
- Emphysema (decreased surface area)

DLco increases in/with:
- Asthma
- Obesity
- Pulmonary hemorrhage
- Left-to-right intracardiac shunt
- Polycythemia
- Post-exercise physiology (increased pulmonary blood volume)

Pulmonary Shunt
When blood bypasses the alveolar membrane by means of an abnormal circulation pathway and reaches the pulmonary venous system with de-oxygenated hemoglobin.
Shunt-like physiology occurs when blood passes through areas of the lung that have very little ventilation (e.g. densely consolidated lung in a severe pneumonia).

Airway Disease

Pneumonia

- see Infectious Diseases, ID7 and Paediatrics, P93

Asthma

- see Family Medicine, FM19 and Paediatrics, P91

Definition
- chronic inflammatory disorder of the airways resulting in episodes of reversible bronchospasm causing airflow obstruction
- associated with reversible airflow limitation and airway hyper-responsiveness to endogenous or exogenous stimuli
- inflamed airways undergo a variety of changes including hypertrophy of smooth airway muscles and hyperplasia of mucous producing goblet cells

Epidemiology
- common, 10.8% of Canadians (3.8 million); 8-10% of adults, 10-15% of children (however often "overdiagnosed" because inaccurate clinical diagnosis, failure to use objective testing)
- most children with asthma significantly improve in adolescence
- often family history of atopy (asthma, allergic rhinitis, eczema)
- work-related asthma (includes work-exacerbated asthma or occupational asthma caused by high or low molecular weight sensitizer exposure)

Airway Obstruction (Decreased FEV_1)
- Asthma
- COPD (chronic bronchitis, emphysema)
- Bronchiectasis (obstructive or mixed)
- Cystic fibrosis (obstructive or mixed)

Red Flags
Severe tachypnea/tachycardia, respiratory muscle fatigue, diminished expiratory effort, cyanosis, silent chest, decreased LOC

Central cyanosis is not detectable until SaO_2 is <85%. It is more easily detected in polycythemia and less readily detectable in anemia

Pathophysiology

- airway obstruction → V/Q mismatch → hypoxemia → ↑ventilation → ↓$PaCO_2$ → ↑pH and muscle fatigue → ↓ventilation, ↑$PaCO_2$/↓pH

Signs and Symptoms

- dyspnea, wheezing, chest tightness, cough, sputum
- symptoms usually occur or worsen at night or early morning
- symptoms can be paroxysmal or persistent
- when having an asthma attack: signs of respiratory distress, pulsus paradoxus

Table 11. Criteria for Determining if Asthma is Well Controlled

Daytime symptoms ≤2 d/wk	No asthma-related absence from work/school
Night-time symptoms <1 night/wk	β2-agonist use ≤2 times/wk
Physical activity normal (unimpaired by symptoms)	FEV_1 or PEF ≥90% of personal best
Exacerbations mild, infrequent (no ER visit, hospitalization, use of prednisone)	PEF diurnal variation <10-15%

Adapted from: Can Respir J 2021; 2:75-78

Table 12. Pulmonary Function Criteria for Diagnosis of Asthma

Preferred Measurement	Alternative Measurements
Spirometry Showing Reversible Airway Obstruction ↓ FEV_1/FVC below lower limit of normal Adults: typically <0.75 to 0.8 Children age 6+: typically <0.8-0.9 AND ↑ FEV_1 ≥12% (and 200 mL in adults) after bronchodilator or a course of controller therapy	**Peak Expiratory Flow Variability** 1. ↓ in PEF after a bronchodilator or course of controller therapy Adults: PEF increase ≥60 L/min (min. 20%) OR Diurnal variation >8% for twice daily readings (>20% for multiple daily readings) Children age 6+: PEF increase ≥20% **Positive Challenge Test** 1. Methacholine challenge: positive if FEV_1 ↓ ≥20% at any inhaled methacholine dose <4 mg/mL (borderline if 4-16 mg/mL is required) 2. Post-exercise: ↓ FEV_1 ≥10-15%

Adapted from: Can Respir J 2012; 19:127-164

Treatment

- environment: identify and avoid triggers
- patient education: features of the disease, goals of treatment, self-management asthma action plan, inhaler technique
- pharmacological
  - symptomatic relief in acute episodes: short-acting β2-agonist or combined, long acting β2-agonist with inhaled corticosteroid (formoterol/budesonide)
  - long-term maintenance: any patient with poor control (Table 11) and/or at risk of exacerbations should be on an inhaled corticosteroid-containing regimen (see Figure 9, R9)
  - risk of exacerbation defined as any of: 1) history of a previous requiring any of: systemic steroids, ED visit or hospitalization, 2) poorly-controlled asthma, 3) overuse of SABA (defined as use of more than 2 inhalers of SABA in 1 year), or 4) current smoker
    1. start with daily inhaled corticosteroids (or long acting β2-agonist with inhaled corticosteroid (formoterol/budesonide) as needed in patients ≥ 12 y/o – especially in patients expected to have low adherence to a daily inhaled corticosteroid)
    2. add long-acting β2-agonists to low dose inhaled corticosteroids in adults (use a combo inhaler never use LABA alone)
    3. escalate inhaled corticosteroid dose
    4. consider LTRA, long-acting anticholinergics, oral corticosteroids, anti-IgE drugs (e.g. omalizumab), anti-IL5 drugs (e.g. mepolizumab)

Emergency Management of Asthma

- see Emergency Medicine, ER29

1. inhaled β2-agonist first line (MDI route and spacer device recommended)
2. systemic steroids (PO or IV if severe)
3. if severe add anticholinergic therapy ± magnesium sulfate
4. rapid sequence intubation in life-threatening cases (plus 100% O_2, monitors, IV access)
5. SC/IV adrenaline if caused by anaphylaxis or if unresponsive to inhaled β2-agonist
6. inhaled corticosteroid maintenance therapy at discharge

Asthma Triggers

Irritants, such as:
- URTIs
- Emotion/anxiety
- Cold air
- Exercise
- GERD
- Cigarette smoke, air pollution
- Strong scents

Allergens, such as:
- Pet dander
- House dust
- Mould
- Cockroaches
- Seasonal allergens (grass/tree/weed/ragweed)

Other:
- NSAIDs (Samter's triad = asthma, NSAID sensitivity, nasal polyps)
- β-blockers (especially non-cardioselective)
- Hormonal fluctuations

Signs of Poor Asthma Control

"DANGERS"
Daytime Sx ≥3 d/wk
Activities (physical) reduced
Night-time Sx ≥1 time/wk
GP visits (unscheduled visits for exacerbations, requiring steroids)
ER visits or hospitalizations for exacerbations
Rescue puffer (SABA) use ≥3 d/wk
School or work absences

Asthma Action Plan

A written plan developed by providers for patients with asthma, which includes signs and symptoms for patients to recognize acute loss of asthma control (typically denoted as 'green' for good control, 'yellow' for transient loss of control, or 'red/emergency' zones) and personalized treatment instructions for each zone (e.g. quadrupling inhaled corticosteroid dose in the yellow zone)

Addition of Long-Acting β2-Agonists to Inhaled Corticosteroids vs. Same Dose Inhaled Corticosteroids for Chronic Asthma in Adults and Children

Cochrane DB Syst Rev 2010;CD005535

Purpose: To quantify the safety and efficacy of addition of LABAs to ICS in asthmatic patients insufficiently controlled on ICS alone.

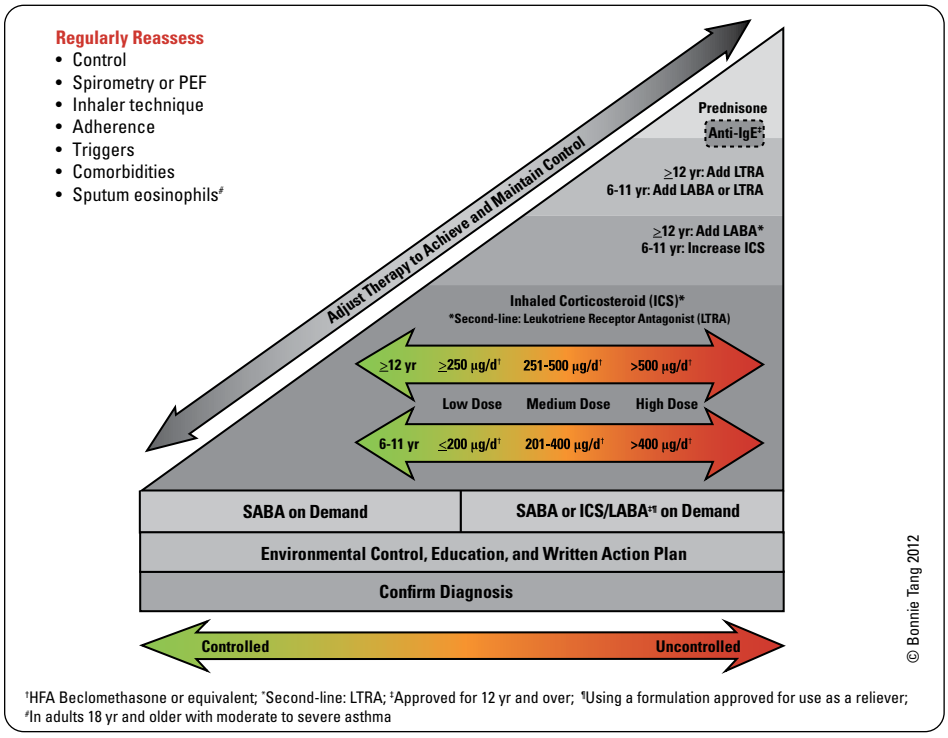
Methods: RCTs comparing addition of inhaled LABAs vs. placebo to the same dose of ICS in children 2 yr and above and in adults were included.

Results: 77 studies, 16623 adults and 4625 children. Addition of a daily LABA to ICS reduced risk of exacerbations requiring oral steroids by 23% and led to a significantly greater improvement in FEV_1 compared to ICS monotherapy.

Conclusions: In adults who are symptomatic on low to high doses of ICS monotherapy, the addition of a LABA reduces rate of exacerbations and improves lung function. In children, the effects of this treatment are uncertain.

Consider adding a LABA to ICS for patients with night-time symptoms

Guidelines for Asthma Management



†HFA Beclomethasone or equivalent; *Second-line: LTRA; ‡Approved for 12 yr and over; ¶Using a formulation approved for use as a reliever; #In adults 18 yr and older with moderate to severe asthma

Figure 9. Guidelines for asthma management
Adapted from: Can Respir J 2021; 2:75-78

Remember to step down therapy to lowest doses which control symptoms/ signs of bronchoconstriction

ICS-Formoterol Reliever vs. ICS and SABA Reliever in Asthma: a Systematic Review and Meta-Analysis
ERJ Open Research 2020;7
Purpose: Conduct a systematic review and meta-analysis to evaluate the efficacy of ICS-formoterol as needed versus ICS-SABA as needed, in patients with mild-moderate asthma.
Methods: RCTs comparing ICS-formoterol and ICS-SABA as-needed in adults and/or children with mild-moderate asthma were included, excluding studies that did not report severe exacerbations. Databases searched were EMBASE, MEDLINE, the Cochrane Central Register of Controlled Trials, and ClinicalTrials.gov. The primary study outcome was time to first exacerbation.
Results: After applying eligibility criteria, 4 RCTs were included in the meta-analysis, all comparing budesonide DPI budesonide-SABA and DPI budesonide-formoterol. Budesonide-formoterol as needed reduced the rate ratio and odds of primary outcome (RR 0.85, 95% CI 0.73 to 1.00; OR 0.86; 95% CI 0.73 to 1.01).
Conclusion: There was a modest 15% reduction in the hazard ratio of first exacerbation with ICS-formoterol as-needed combination versus the ICS-SABA maintenance regimen. Currently, there remains no agreed standard for a minimal clinically important difference. Overall, this study is consistent with the GINA 2020 recommendations preferring ICS-formoterol as-needed over ICS maintenance therapy as a step 2 if time to severe exacerbation is a priority.

Chronic Obstructive Pulmonary Disease

• see Family Medicine, FM19

Definition

- progressive and irreversible condition of the lung characterized by chronic obstruction to airflow with many patients having periodic exacerbations, gas trapping, lung hyperinflation, and at end stages, weight loss
- spirometry required for diagnosis (post-bronchodilator FEV_1/FVC <0.70 or lower limit of normal)
- 2 phenotypes: chronic bronchitis and emphysema (usually coexist to variable degrees)
- gradual decrease in FEV_1 over time, more rapidly with each acute exacerbation

Table 13. Clinical and Pathologic Features of COPD*

Chronic Bronchitis	Emphysema
Defined Clinically	**Defined Pathologically**
Productive cough on most days for at least 3 consecutive months in 2 successive years Obstruction is mostly due to narrowing of the airway lumen by mucosal thickening and excess mucus Airway changes include increased goblet cells, fibrosis of bronchioles, loss of tethering due to destruction of alveolar walls	Dilation and destruction of air spaces distal to the terminal bronchiole without obvious fibrosis Decreased elastic recoil of lung parenchyma causes decreased expiratory driving pressure, airway collapse (obstruction), and air trapping
	2 Types 1. Centrilobular (respiratory bronchioles predominantly affected) Typical form seen in smokers, primarily affects upper lung zones 2. Panacinar (all parts of acinus) Accounts for about 1% of emphysema cases, typically from α1-antitrypsin deficiency, primarily affects lower lobes

*Note that the pathological changes of chronic bronchitis and emphysema can exist without obstruction. Only if spirometric obstruction is also present is it termed COPD.

Risk Factors

- smoking is the #1 risk factor
- environmental: exposure to wood smoke or other biomass fuel for cooking (especially in developing countries), air pollution, occupational exposures
- treatable factors: α1-antitrypsin deficiency, concurrent bronchial hyperactivity ("asthma-COPD overlap - ACO")
- demographic factors: age, FMHx of atopy, history of childhood respiratory infections, low socioeconomic status

Natural Progression of COPD

40s	Chronic productive cough, wheezing occasionally
50s	1st acute chest illness
60s	Dyspnea on exertion, increasing sputum, more frequent exacerbations
Late Stage	Hypoxemia with cyanosis, polycythemia, hypercapnia (morning headache), cor pulmonale, weight loss

Complications of COPD

- Chronic hypoxemia
- Polycythemia 2° to hypoxemia
- Pulmonary HTN from loss of vascular bed (emphysema)
- Cor pulmonale
- Pneumothorax due to rupture of emphysematous bullae
- Depression
- COPD exacerbations

CO_2 Retainers
On ABG, retainers have chronically elevated CO_2 levels, usually with a near normal pH (due to metabolic compensation). Maintain O_2 saturation between 88-92% to prevent exacerbating hypercapnia due to worsening V/Q mismatch, Haldane effect, and/or decreased respiratory drive (in order of physiologic importance)

Remember, first line therapy for COPD patients who smoke is smoking cessation

Signs and Symptoms

Table 14. Clinical Features and Investigations for Emphysema and Chronic Bronchitis

	Symptoms	Signs	Investigations
Chronic Bronchitis (Blue Bloater*)	Chronic productive cough Purulent sputum	Cyanosis (2° to hypoxemia) Peripheral edema from RHF (cor pulmonale) Crackles, wheezes Prolonged expiration Frequently obese	**PFT:** ↓ FEV_1, ↓ FEV_1/FVC N TLC, ↓ or N DL_{CO} **CXR:** AP diameter normal ↑ bronchovascular markings Enlarged heart with cor pulmonale (end-stage)
Emphysema (Pink Puffer*)	Dyspnea (± exertion) Minimal cough Tachypnea Decreased exercise tolerance	Pink skin Pursed-lip breathing Accessory muscle use Cachectic appearance due to calorie consumption from increased work of breathing Hyperinflation/barrel chest Hyperresonant percussion Decreased breath sounds Decreased diaphragmatic excursion	**PFT:** ↓ FEV_1, ↓ FEV_1/FVC ↑ TLC (hyperinflation) ↑ RV (gas trapping) ↓ DL_{CO} **CXR:** ↑ AP diameter Flat hemidiaphragm (on lateral CXR) ↓ cardiac silhouette ↑ retrosternal space Bullae ↓ peripheral vascular markings

*Note that "blue bloater" and "pink puffer" phenotypes are extremes and most COPD patients have elements of both. They are also outdated terms rarely used in clinical practice.

Table 15. Treatment of Stable COPD

Treatment	Details
PROLONG SURVIVAL	
Smoking Cessation	Counselling, nicotine replacement (long + short-acting), bupropion, varenicline, combinations thereof
Vaccination	Annual influenza vaccination
Home Oxygen	Prevents cor pulmonale and decreases mortality if used >15 h/d; indicated if: (1) $PaO_2 \leq 55$ mmHg or (2) PaO_2 56-59 mmHg with cor pulmonale or polycythemia
SYMPTOMATIC RELIEF (no mortality benefit)	
Bronchodilators (mainstay of current drug therapy, used in combination)	Short-acting anticholinergics (e.g. ipratropium bromide) SABAs (e.g. salbutamol, terbutaline)
	SABAs: rapid onset but significant side effects at high doses (e.g. hypokalemia)
	Short-acting anticholinergics slightly more effective than SABAs with fewer side effects but slower onset
	Using a combination of both is superior to monotherapy
	LABAs (e.g. salmeterol, formoterol, indacaterol) and long-acting anticholinergics (e.g. tiotropium bromide, glycopyrronium bromide)
	More sustained effects for moderate to severe COPD
	LAMAs more effective at decreasing exacerbation than LABAs
	Using a combination of both is superior than monotherapy
	ICS + LABA combination (e.g. Advair®: fluticasone + salmeterol, Symbicort®: budesonide + formoterol) (for patients with frequent exacerbations of end-stage disease)
	Theophylline: weak bronchodilator; limited evidence to suggest combination with bronchodilator (high-risk toxicity profile: nervous tremor, nausea/vomiting/diarrhea, tachycardia, arrhythmias, sleep changes)
	PDE4 inhibitor: roflumilast (Daxas®) anti-inflammatory medication useful in chronic bronchitis phenotype with severe airflow obstruction, and frequent exacerbations
Corticosteroids	ICS monotherapy has been shown to increase the incidence of pneumonia in COPD; ICS should only be used as part of a combination inhaler with LABA or with LABA + LAMA (triple therapy), in patients with a history of exacerbations, end-stage disease, and/or concomitant asthma
	Oral steroids are important when treating exacerbations; chronic systemic glucocorticoids are generally not recommended due to unfavourable risk-benefit ratio
Surgical	Lung volume reduction surgery (resection of emphysematous parts of lung, associated with higher mortality if FEV_1 <20%), lung transplant
Other	Patient education, eliminate respiratory irritants/allergens (occupational/environmental), exercise rehabilitation to improve physical endurance
	Pulmonary rehabilitation: may reduce mortality if offered within 2 wk after hospitalization with an acute exacerbation of COPD; should be offered to any patient with high symptom burden and/or frequent exacerbations

GOLD Classification of the Severity of COPD

- GOLD 1: Mild FEV_1 ≥80% of predicted
- GOLD 2: Moderate 50% ≤FEV_1 <80% of predicted
- GOLD 3: Severe 30% ≤FEV_1 <50% of predicted
- GOLD 4: Very Severe FEV_1 <30% of predicted

Note: Use COPD Assessment Tool for comprehensive assessment of symptoms, weak correlation between FEV_1 and symptoms

Systemic Corticosteroids for Acute Exacerbations of Chronic Obstructive Pulmonary Disease
Cochrane DB Syst Rev 2014;9:CD001228
Study: Cochrane systematic review 16 studies.
Population: 1787 patients with acute COPD exacerbations.
Intervention: Oral or parenteral corticosteroids vs. placebo.
Outcome: Treatment failure, risk of relapse, time to next COPD exacerbation, likelihood of adverse event, length of hospital stay, and lung function at end of treatment.
Results: Systemic corticosteroids reduced the risk of treatment failure by over half compared with placebo in nine studies (n=917) with median treatment duration 14 d, odds ratio (OR) 0.48 (95% CI 0.35-0.67). The evidence was graded as high quality and it would have been necessary to treat nine people (95% CI 7-14) with systemic corticosteroids to avoid one treatment failure. There was moderate-quality evidence for a lower rate of relapse at 1 mo for treatment with systemic corticosteroid in two studies (n=415) (hazard ratio (HR) 0.78; 95% CI 0.63-0.97). Mortality up to 30 d was not reduced by treatment with systemic corticosteroid compared with control in 12 studies (n=1319; OR 1.00; 95% CI 0.60-1.66). FEV_1, measured up to 72 hours, showed significant increase (7 studies; n=649; mean difference (MD) 140 mL; 95% CI 90-200); however, this benefit was not observed at later time points. The likelihood of adverse events increased with corticosteroid treatment (OR 2.33; 95% CI 1.59-3.43). The risk of hyperglycemia was significantly increased (OR 2.79; 95% CI 1.86-4.19). For general inpatient treatment, duration of hospitalization was significantly shorter with corticosteroid treatment (MD -1.22 d; 95% CI -2.26 to -0.18), with no difference in length of stay in the intensive care unit (ICU) setting. Comparison of parenteral vs. oral treatment showed no significant difference in the primary outcomes of treatment failure, relapse, mortality or for any secondary outcomes.
Conclusion: There is high-quality evidence to support treatment of exacerbations of COPD with systemic corticosteroid by the oral or parenteral route in reducing the likelihood of treatment failure and relapse at 1 mo, shortening length of stay in hospital inpatients not requiring assisted ventilation in ICU and providing earlier improvement in lung function and symptoms. There is no evidence of benefit for parenteral treatment compared with oral treatment with corticosteroid on treatment failure, relapse or mortality. There is an increase in adverse drug effects with corticosteroids treatment, which is greater with parenteral administration compared with oral treatment.

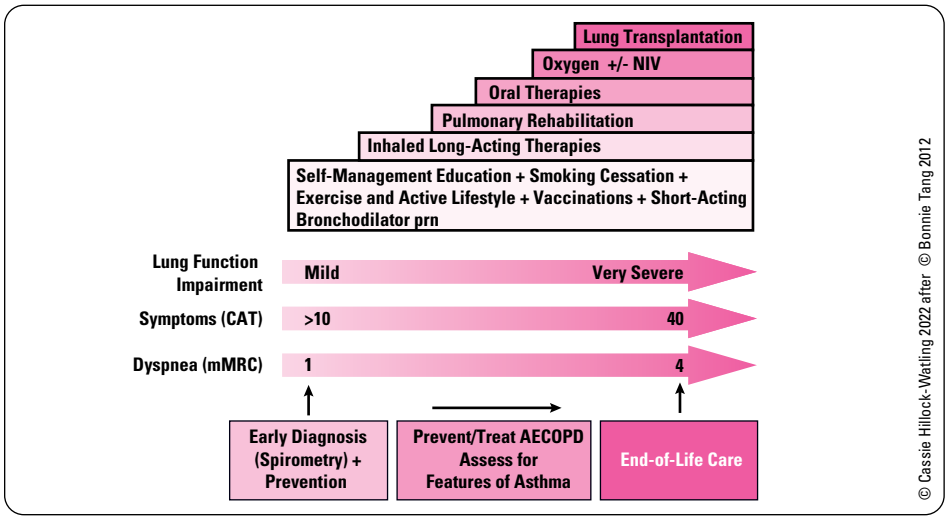


Figure 10. Guidelines for COPD management
Adapted from: Canadian Thoracic Society Clinical Practice Guideline on pharmacotherapy in patients with COPD – 2019 update of evidence. Can J Respir Crit Care Sleep Med 2019; 3:4, 210-232

Acute Exacerbations of COPD

- definition
  - sustained (>48 h) worsening of dyspnea, cough, or sputum production leading to an increased use of medications
  - in addition, defined as either purulent or non-purulent (to predict need for antibiotic therapy)
- etiology: viral URTI, bacteria, air pollution, CHF, PE, MI
- management
  - ABCs, consider NIV if high CO_2 with reduced pH
  - O_2: target 88-92% SaO_2 for CO_2 retainers
  - bronchodilators by MDI with spacer or nebulizer
  - SABA + anticholinergic, e.g. salbutamol and ipratropium bromide via nebulizers × 3 back-to-back q15 min
  - systemic corticosteroids: oral prednisone or IV methylprednisolone
  - antibiotics for purulent COPD exacerbations
  - patients with no risk factors for resistant organisms: any of doxycycline/macrolide/amoxicillin/etc.
  - patients with risk factors for resistant organisms: amoxicillin/clavulanic acid or respiratory fluoroquinolone
  - post exacerbation: rehabilitation within 2 wk if possible
- ICU admission
  - for life-threatening exacerbations
  - ventilatory support
  - non-invasive: NIPPV (BiPAP)
  - conventional mechanical ventilation

Prognosis in COPD

- prognostic factors
  - frequency and severity of acute exacerbations is the single best predictor
  - lung function tests and modified Medical Research Council (mMRC) dyspnea scale add value
  - development of hypoxemia, hypercapnia, or cor pulmonale
- 5 yr survival
  - FEV_1 <1 L = 50%
  - FEV_1 <0.75 L = 33%
- **BODE** index for risk of death in COPD
  - greater score = higher probability the patient will die from COPD; score can also be used to predict hospitalization
  - 10 point index consisting of four factors:
  - **B**ody mass index (BMI): ≤21 (+1 point)
  - **O**bstruction (FEV_1): 50-64% (+1), 36-49% (+2), <35% (+3)
  - **D**yspnea (mMRC scale): walks slower than people of same age on level surface, stops occasionally (+1), stops at 100 yards or a few minutes on the level (+2), too breathless to leave house or breathless when dressing/undressing (+3)
  - **E**xercise capacity (6 min walk distance): 250-349 m (+1), 150-249 m (+2), <149 m (+3)

Dual Combination Therapy vs. Long-Acting Bronchodilators Alone for Chronic Obstructive Pulmonary Disease (COPD): A Systematic Review and Network Meta-Analysis
Cochrane DB Syst Rev 2018;CD012620.
Study: Cochrane systematic review of 99 studies
Population: 101311 participants with moderate to severe COPD.
Intervention: Four different groups of inhalers (i.e. LABA/LAMA combination, LABA/ICS combination, LAMA and LABA).
Outcome: COPD exacerbations (moderate to severe and severe), symptom and quality-of-life scores, safety outcomes, and lung function.
Result: LABA/LAMA combination therapy is most effective in reducing COPD exacerbations, followed by LAMA in high-risk and low-risk populations. LABA/LAMA decreases moderate-to-severe exacerbations compared to LABA/ICS (HR 0.86; 95% credible interval (CrI) 0.76-0.99), LAMA (HR 0.87; 95% CrI 0.78 to 0.99), and LABA in high-risk populations (HR 0.70; 95% CrI 0.61-0.80). LAMA decreases moderate-to-severe exacerbations compared to LABA in high-risk (HR 0.80; 95% CrI 0.71-0.88) and low-risk populations (HR 0.87; 95% CrI 0.78-0.97). LABA/LAMA decreases severe exacerbations compared to LABA/ICS (HR 0.78; 95% CrI 0.64-0.93) and LABA (HR 0.64; 95% CrI 0.51-0.81) in high-risk populations. There was a general trend of the combination therapies having greater improvement in symptom and quality of life scores compared to monotherapies. LABA/ICS was the lowest ranked for pneumonia serious adverse events in high-risk and low-risk populations. LABA/ICS increases the odds of pneumonia compared to LAMA/LABA (OR 1.69; 95% CrI 1.20-2.44), LAMA (OR 1.78; 95% CrI 1.33-2.39), LABA (OR 1.50; 95% CrI 1.17-1.92). The mean difference in lung function for LABA/LAMA versus LABA in high-risk population exceeded the minimal clinically important difference (mean difference 0.13 L: 95% CrI 0.10-0.15).
Conclusions: LABA/LAMA combination therapy is most effective in reducing COPD exacerbations. LAMA-containing therapies may be superior to therapies without LAMA at reducing COPD exacerbations. Combination therapies may be more effective than monotherapies for improving symptoms and quality of life scores. Therapies that contain ICS are associated with an increased risk of pneumonia. The mean difference in lung function when comparing LABA/LAMA versus LABA is significant.

Pulmonary Embolism in Patients with Unexplained Exacerbation of COPD: Prevalence and Risk Factors
Ann Intern Med 2006;144:390-396
Study: Prospective cohort study
Population: 211 current or former smokers with COPD who were admitted to the hospital for severe exacerbation of unknown origin and did not require invasive mechanical ventilation.
Measurements: All patients received spiral CT angiography (CTA) and venous compression ultrasonography of both legs.
Outcomes: PE positive or PE negative.
Results: 25% of patients met diagnostic criteria for PE (+ CTA or + U/S).
Conclusions: Prevalence of PE in patients hospitalized for COPD exacerbation of unknown origin is 25%. Therefore, all patients presenting to hospital with COPD exacerbation without obvious cause require PE workup (leg dopplers or CTA – decision of which to use depends on pre-test probability of the patient).

Bronchiectasis

Definition
- irreversible dilatation of airways due to inflammatory destruction of airway walls resulting from persistently impaired mucous clearance and/or infected mucus
- usually affects medium sized airways
- the most common sputum pathogens found in patients with non-cystic fibrosis are *H. influenzae, P. aeruginosa*, and *M. catarrhalis*

Table 16. Etiology and Pathophysiology of Bronchiectasis

Obstruction	Post-Infectious (results in dilatation of bronchial walls)	Impaired Defenses/Drainage (leads to chronic infections and inflammation)
Tumour Foreign body	Pneumonia TB Nontuberculous mycobacterium (NTM) Measles Pertussis	Hypogammaglobulinemia CF Defective leukocyte function Allergic bronchopulmonary aspergillosis Ciliary dysfunction (Kartagener's syndrome: bronchiectasis, sinusitis, situs inversus)

Signs and Symptoms
- chronic cough, copious purulent sputum (but 10-20% have dry cough), dyspnea, fatigue, chronic rhinosinusitis, hemoptysis (can be massive), recurrent pneumonia, local crackles (inspiratory and expiratory), rhonchi, wheezes
- may be difficult to differentiate from chronic bronchitis

Investigations
- PFTs: often demonstrate obstructive pattern but may be normal
- CXR
  - nonspecific: increased markings, linear atelectasis, loss of volume in affected areas
  - specific: "tram tracking" – parallel narrow lines radiating from hilum, cystic spaces, like structures
- high-resolution thoracic CT (diagnostic, gold standard)
  - 87-97% sensitivity, 93-100% specificity
  - "signet ring": dilated bronchi with thickened walls where diameter of bronchus is >1.5x diameter of accompanying artery
- sputum cultures (routine + acid-fast bacillus)
- CBC
- LFTs
- immunoglobulin panel (serum Ig levels), α-1 antitrypsin level, immunology panel (ANA, ENAs)
- sweat chloride if cystic fibrosis is suspected (upper zone predominant, concomitant features)

Treatment
- vaccination: influenza and pneumococcal vaccinations
- chest physiotherapy, breathing exercises, physical exercise
- antibiotics (oral, IV, inhaled):
  - inhaled: used chronically to decrease bacterial load, in patients with frequent exacerbations, especially if *Pseudomonas* in sputum
  - oral/IV: routinely used for exacerbations, driven by sputum sensitivity when available; macrolides may be used chronically for an anti-inflammatory effect chronically to reduce exacerbation frequency in patients with frequent exacerbations
- mucolytics (hypertonic saline)
- inhaled corticosteroids: only use if the patient has asthma or other co-existing disease as an indication
- oral corticosteroids have no role in acute, major exacerbations
- pulmonary resection: in selected cases with focal bronchiectasis
- transplant: for end stage diffuse causes (e.g. primary ciliary dyskinesia)

Cystic Fibrosis

- see Paediatrics, P92

Pathophysiology
- chloride transport dysfunction: thick secretions from exocrine glands (lung, pancreas, reproductive tract), and blockage of secretory ducts

Clinical Features
- multisystem: results in severe lung disease, pancreatic insufficiency, salt loss syndrome, and azoospermia
- other manifestations: meconium ileus in infancy, distal ileal obstruction in adults, CF-related DM, sinusitis, liver disease, bone disease, and malnutrition

European Respiratory Society Guidelines on Long-term Home Non-invasive Ventilation for Management of COPD
Eur. Respir. 2019;54
Purpose: While the role of non-invasive ventilation (NIV) has been shown to improve outcomes in acute COPD exacerbations with hypercapnic respiratory failure, the efficacy of long-term home NIV for COPD management is not as well studied. This document provides evidence-based recommendations for long-term home (LTH) NIV in chronic hypercapnic COPD patients.
Methods: The task force panel consisted of 15 clinical experts in the field of NIV and several other clinicians, tasked with discussing an initial list of PICO questions. Following the GRADE procedure, the task force rated each outcome for its perceived importance in clinical decision-making.
Conclusions: Pooled data over 12 RCTs showed poor benefit for LTH-NIV in decreasing PaCO2 or increasing PaO2. Pooled data from 5 RCTs showed that NIV decreases dyspnea score (SMD -0.51, 95% CI -0.06 to -0.95), exercise capacity and pulmonary rehabilitation outcomes. The task force recommends LTH-NIV be used in patients with COPD following a life-threatening episode of acute hypercapnic respiratory failure requiring acute NIV, if hypercapnia persists following the initial episode. It is recommended to titrate LTH-NIV to normalize or reduce PaCO2 levels in patients with COPD. The task force supports using fixed pressure modes as first-choice ventilator modes in patients with COPD using LTH-NIV.

Different Durations of Corticosteroid Therapy for Exacerbations of Chronic Obstructive Pulmonary Disease
Cochrane DB Syst Rev 2018;CD006897
Study: Cochrane systematic review. 8 studies.
Population: 582 patients, with severe or very severe COPD.
Intervention: Corticosteroids given at equivalent daily doses for 3-7 d (short duration) vs. 10-15 d (longer-duration).
Outcome: Treatment failure, risk of relapse, time to next COPD exacerbation, likelihood of adverse event, length of hospital stay, and lung function at end of treatment.
Results: In four studies there was no difference in risk of treatment failure between short-duration and longer-duration systemic corticosteroid treatment (n=457; odds ratio (OR) 0.72, 95% confidence interval (CI) 0.36-1.46). No difference in risk of relapse (a new event) was observed between short-duration and longer-duration systemic corticosteroid treatment (n=457; OR 1.04, 95% CI 0.70-1.56). Time to the next COPD exacerbation did not differ in one large study that was powered to detect non-inferiority and compared 5 d vs. 14 d of systemic corticosteroid treatment (n=311; hazard ratio 0.95, 95% CI 0.66-1.37). In five studies no difference in the likelihood of an adverse event was found between short-duration and longer-duration systemic corticosteroid treatment (n=503; OR 0.89, 95% CI 0.46-1.69. Length of hospital stay (n=421; mean difference (MD) -0.61 d, 95% CI -1.51-0.28) and lung function at the end of treatment (n=185; MD FEV1 -0.04 L; 95% CI -0.19-0.10) did not differ between short-duration and longer-duration treatment.
Conclusion: 5 d of oral corticosteroids is likely to be sufficient for treatment of adults with acute exacerbations of COPD, and this review suggests that the likelihood is low that shorter courses of systemic corticosteroids (of around five days) lead to worse outcomes than are seen with longer (10 to 14 d) courses.

- chronic lung infections
  - *S. aureus* and *H. influenzae*: early
  - *P. aeruginosa*: most common in adulthood
  - *B. cepacia* complex: worse prognosis (some subtypes) so infection control is key
  - in adults, colonization with more resistant bacteria increases (e.g. PsA, *Burkholderia cepacia* complex, *Stenotrophomonas, Achromobacter*, MRSA, NTM etc.)

Investigations
- genetic testing
  - autosomal recessive- more than 2100 mutations in CFTR described, not all disease causing
- sweat chloride test
  - increased concentrations of NaCl and K^+ ($[Cl^-]$ >60 mmol/L on two occasions supports the diagnosis)
  - carriers have normal sweat tests (and no symptoms)
- PFTs
  - early: airflow limitation in small airways
  - late: severe airflow obstruction, hyperinflation, gas trapping
- ABGs
  - hypoxemia, hypercapnia later in disease with eventual respiratory failure, and cor pulmonale
- CXR
  - hyperinflation, increased pulmonary markings (especially upper lobes)

Treatment
- chest physiotherapy
- pancreatic enzyme replacements, high fat, high calorie diet
- bronchodilators (salbutamol ± ipratropium bromide)
- inhaled mucolytic (reduces mucus viscosity): hypertonic saline, DNase
- inhaled antibiotics (tobramycin, colistin, aztreonam, levofloxacin, vancomycin)
- anti-inflammatory medications (e.g. azithromycin, ICS in some)
- antibiotics oral and IV (targeted to sputum growth if available, e.g. ciprofloxacin for *Pseudomonas*)
- CFTR potentiators and modulators (e.g. Ivacaftor, Orkambi®, Symdeko®)
- lung transplant

Prognosis
- depends on: infections (*B. cepacia* colonization), FEV_1, acute pulmonary exacerbations, and lung transplant vs. non-lung transplant
- female gender and low socioeconomic class have greater risk of early death

Usually presents in childhood as recurrent lung infections that become persistent and chronic

Correctors (Specific Therapies For Class II CFTR Mutations) for Cystic Fibrosis
Cochrane Database Syst. Rev. 2018;8:CD010966
Purpose: To evaluate the effects of cystic fibrosis transmembrane receptor (CFTR) correctors on clinically important outcomes, both benefits and harms, in children and adults with CF and class II CFTR mutations (most commonly F508del).
Methods: RCTs comparing CFTR correctors to placebo in people with CF class II mutations were searched in the Cochrane Cystic Fibrosis and Genetic Disorders Cystic Fibrosis Register. Two authors independently extracted data and assessed risk of bias and quality of evidence using GRADE criteria.
Results: The quality-of-life scores (respiratory domain) favoured combination therapy (both lumacaftor-ivacaftor and tezacaftor-ivacaftor) compared to placebo at all time points. The mean increase in cystic fibrosis questionnaire (CFQ) scores with twice-daily tezacaftor (100 mg) and ivacaftor (150 mg) was approximately 5 points (95% CI 3.20 to 7.00; 504 participants; moderate quality evidence). FEV1%-predicted improved with both combination therapies compared to placebo at 6 mo, by 5.21% with lumacaftor-ivacaftor OD (95% CI 3.61% to 6.80%; 504 participations; high quality evidence), and by 2.40% with lumacaftor-ivacaftor BID (95% CI 0.40% to 4.40%; 204 participants; low-quality evidence). More participants receiving the lumacaftor-ivacaftor combination reported early breathlessness (OR 2.05; 99% CI 1.10 to 1.83; 739 participants; high quality evidence). These adverse effects were not reported in the tezacaftor-ivacaftor studies.
Conclusions: Overall, the deployment of combination CFTR corrector therapies improve quality-of-life and lung function in patients with class II CF, compared to placebo controls. Adverse drug effects can be mitigated with the use of tezacaftor-ivacaftor, when clinically indicated.

Interstitial Lung Disease

Definition
- a group of disorders which cause diffuse parenchymal lung disease, with progressive scarring of lung tissue and impairment in lung function and gas exchange

Pathophysiology
- inflammatory and/or fibrosing process in the alveolar walls ➔ distortion and destruction of normal alveoli and microvasculature
- typically associated with:
  - lung restriction (decrease in TLC and VC)
  - decreased lung compliance (increased or normal FEV_1/FVC)
  - impaired diffusion (decreased DL_{CO})
  - hypoxemia due to V/Q mismatch (usually without hypercapnia until end stage)
  - pulmonary HTN and cor pulmonale occur with advanced disease secondary to hypoxemia and blood vessel destruction

Etiology
- IPF is the most common cause; however, there are numerous other causes including medication and radiation related disease
- a careful review of risk factors (e.g. organic/inorganic exposures, connective tissue disease symptoms, occupational history, medications) is needed during patient evaluation

In ILD think
FASSTEN and BAD RASH

Upper Lung Disease (FASSTEN)
Farmer's lung (hypersensitivity pneumonitis)
Ankylosing spondylitis
Sarcoidosis
Silicosis
TB
Eosinophilic granuloma (Langerhans-cell histiocytosis)
Neurofibromatosis

Lower Lung Disease (BADRASH)
Bronchiolitis obliterans with organizing pneumonia (BOOP)/Cryptogenic Organizing Pneumonia (COP)
Asbestosis
Drugs (nitrofurantoin, hydralazine, INH, amiodarone, many chemo drugs)
Rheumatologic disease
Aspiration
Scleroderma
Hamman Rich (acute interstitial pneumonia) and IPF

Table 17. Interstitial Lung Diseases

UNKNOWN ETIOLOGY	KNOWN ETIOLOGY				
Idiopathic Interstitial Pneumonias	**ILD Associated with Systemic Rheumatic Disorders**	**ILD Associated with Drugs or Treatments**	**Inherited Disorders**	**Granulomatous Disease**	**Other**
IPF (idiopathic pulmonary fibrosis)	Scleroderma	Antibiotics (nitrofurantoin)	Familial IPF	Hypersensitivity pneumonitis (usually organic antigen)	Langerhans-cell histiocytosis
NSIP (non-specific interstitial pneumonia)	Rheumatoid arthritis	Anti-inflammatory agents (methotrexate)	Telomerase mutations	Sarcoidosis	LAM (lymphangioleio-myomatosis)
RB-ILD (respiratory bronchiolitis related ILD)	Systemic lupus erythematosus (SLE)	Cardiovascular drugs (amiodarone)	Neurofibromatosis	Granulomatous lymphocytic ILD	Chronic eosinophilic pneumonia
DIP (desquamative interstitial pneumonia)	Polymyositis/ dermatomyositis	Antineoplastic agents (chemotherapy agents)	Tuberous sclerosis		
COP (cryptogenic organizing pneumonia)	Anti-synthetase syndromes	Recreational drugs (e.g. crack lung, talc granulomatosis)	Gaucher's disease		
AIP (acute interstitial pneumonia)	Mixed connective tissue disease	Radiation	Pneumoconioses (inorganic dust) (Silicosis Asbestosis Coal workers' pneumoconiosis Chronic beryllium disease)		
LIP (lymphocytic organizing pneumonia)	ANCA associated vasculitis				
IPPFE (idiopathic pleuroparenchymal fibroelastosis)	Sjogren's syndrome				
AFOP (acute fibrinous and organizing pneumonia)					

Signs and Symptoms

- dyspnea, especially on exertion
- nonproductive cough
- crackles (dry, fine, end-inspiratory)
- clubbing (especially in IPF and asbestosis)
- features of cor pulmonale
- note that signs and symptoms vary with underlying disease process
  - e.g. sarcoidosis is seldom associated with crackles and clubbing

Investigations

- CXR (see Medical Imaging, MI4)
  - usually decreased lung volumes
  - reticular, nodular, or reticulonodular pattern (nodular <3 mm)
  - hilar/mediastinal adenopathy (bilateral especially in sarcoidosis)
  - honeycombing
- CT (see Medical Imaging, MI6)
  - four categories when interpreting CT imaging for idiopathic ILD
  - UIP – reticulation, subpleural and basal predominant, honeycombing ± traction bronchiectasis
  - probable UIP – reticulation, subpleural and basal predominant, traction bronchiectasis
  - indeterminate for UIP – subtle reticulation, subpleural and basal predominant ("early UIP"), CT features that do not suggest any specific etiology
  - alternative diagnosis to IPF – CT features of cysts, mosaic attenuation, predominant ground-glass opacity, profuse micronodules, centrilobular nodules, consolidation, mid or upper lung zone predominance, peribronchovascular distribution
- PFTs
  - restrictive pattern: decreased lung volumes and compliance
  - normal or increased FEV_1/FVC, e.g. flow rates are often normal or high when corrected for absolute lung volume
  - DL_{CO} decreased
- ABGs
  - hypoxemia and respiratory alkalosis may be present with progression of disease

The CXR can be normal in up to 10% of patients with interstitial lung disease

- other
  - ANA, RF and anti-CCP, ANCA, and myositis antibodies are performed on a case-by-case basis, serum-precipitating antibodies to inhaled organic antigens (hypersensitivity pneumonitis)
  - bronchoscopy with lavage in select cases
  - surgical lung biopsy is considered in patients with CT imaging showing an indeterminate for UIP and alternative diagnosis to IPF pattern

Unknown Etiologic Agents

IDIOPATHIC PULMONARY FIBROSIS

Definition
- pulmonary fibrosis of unknown cause with UIP histology (found on biopsy or inferred from CT)
- a progressive, irreversible condition
- DDx: connective tissue disease associated-ILD, chronic hypersensitivity pneumonitis, asbestosis, NSIP

Signs and Symptoms
- commonly presents over age 50, incidence rises with age; males > females
- dyspnea on exertion, nonproductive cough, constitutional symptoms, late inspiratory fine crackles at lung bases, clubbing

Investigations
- labs (nonspecific, autoimmune serology usually negative)
- CXR: reticular or reticulonodular pattern with lower lung predominance; often see honeycombing in advanced disease
- high resolution CT: typical pattern is one of UIP; ground glass, consolidation, or nodules should not be prominent in IPF
- biopsy: only if patient has an indeterminate for UIP or alternative diagnosis to IPF pattern on CT imaging

Treatment
- acute exacerbation:
  - prednisone
  - antibiotics and diuretics are considered on an individualized basis +/- mechanical ventilation
- ongoing management:
  - antifibrotic therapy – pirfenidone or nintedanib (anti-fibrotics)
  - smoking cessation + pulmonary rehab +/- O_2
  - PPI if patient has reflux
  - lung transplantation for advanced disease
  - prednisone is not used in chronic disease management as it increases mortality, but can be used during acute exacerbations

IPF Prevalence
- Age 35-44: 2-7 per 100000
- Age >75: 175 per 100000

See Landmark Respirology Trials table for more information on ASCEND, which details the efficacy and safety of oral Pirfenidone in patients with idiopathic pulmonary fibrosis

Most common presentation of sarcoidosis: asymptomatic CXR finding

Hilar adenopathy refers to enlargement of mediastinal lymph nodes which is most often seen by standard CXR as spherical/ellipsoidal and/or calcified nodes. If unilateral, think neoplasia, TB, or sarcoid. If bilateral, think sarcoid or lymphoma

Corticosteroids for Pulmonary Sarcoidosis
Cochrane DB Syst Rev 2005;2:CD001114
Study: Cochrane systematic review of 13 RCTs.
Population: 1066 participants with pulmonary sarcoidosis
Interventions: steroids (oral or inhaled) versus control
Outcomes: Improved CXR
Results: Oral steroids demonstrated an improvement in CXR (RR 1.46, 95% CI 1.01-2.09). For inhaled corticosteroids, two studies showed no improvement in lung function and one study showed an improvement in diffusing capacity. No data on side-effects.
Conclusions: Oral steroids improve CXR findings and global scores of CXR, symptoms, and spirometry over 3-24 mo, but do not improve lung function or modify disease course. Oral steroids may be of benefit for patients with Stage 2 and 3 disease.

CXR Fibrotic Patterns
- Asbestosis: lower > upper lobes
- Silicosis: upper > lower lobes
- Coal: upper > lower lobes

Known Etiologic Agents

HYPERSENSITIVITY PNEUMONITIS

Definition
- also known as extrinsic allergic alveolitis, hypersensitivity pneumonitis (HP) is a spectrum of immune-mediated lung disorders occurring in response to an inhaled organic antigen

Pathogenesis
- two hit hypothesis: genetic susceptibility/environmental factors plus antigen exposure
- subacute and acute HP are mediated through immune complex formation and inflammation
- chronic HP results from type IV hypersensitivity reaction, T-cell mediated granulomatous inflammatory response

Etiology
- caused by sensitization to inhaled agents, usually organic dust
- exposure often related to occupation or hobby
  - farmer's lung (thermophilic actinomycetes)
  - bird breeder's/bird fancier's lung (immune response to bird antigen)
  - humidifier lung (*Aureobasidium pullulans*)
  - sauna taker's lung (*Aureobasidium* spp.)
  - metalworking fluid lung
- may have no identified antigen. If so, likely represents something in the home environment

Signs and Symptoms
- acute presentation: (4-6 h after exposure)
  - dyspnea, cough, fever, chills, malaise (lasting 18-24 h)

- subacute presentation: more insidious onset than acute presentation
- chronic presentation
  - insidious onset over years
  - dyspnea, cough, malaise, anorexia, weight loss

Investigations
- CXR
  - acute: diffuse infiltrates, predominantly upper lobe
  - chronic: predominantly upper lobe reticulonodular pattern
- PFTs: acute HP is often obstructive, subacute is obstructive/mixed, chronic is progressively restrictive
- in both acute and chronic reactions, serum precipitins may be detectable (neither sensitive nor specific)

Histopathology
- acute HP triad: poorly formed granulomas, cellular bronchiolitis, interstitial lymphocytic infiltrate
- subacute/chronic HP: poorly formed granulomas and multinucleated giant cells are often seen, may be difficult to distinguish from UIP

Treatment
- early diagnosis: avoidance of further exposure is critical as chronic changes are irreversible
- systemic corticosteroids can relieve symptoms and speed resolution
- steroid-sparing agents (e.g. mycophenolate, azathioprine) are often used in setting of progressive disease despite steroids or to prevent steroid related side-effects

SARCOIDOSIS

Definition
- idiopathic non-infectious granulomatous multi-system disease with lung involvement in 90%
- characterized pathologically by non-necrotizing granulomas (although occasionally necrosis is present)
- numerous human leukocyte antigens and other genetic markers have been shown to play a role and familial sarcoidosis is now recognized

Epidemiology
- typically affects young and middle-aged patients
- higher incidence among people of African descent (in USA) and from northern latitudes (e.g. Scandinavia, Canada)

Signs and Symptoms
- asymptomatic, cough, dyspnea, fever, arthralgia, malaise, erythema nodosum, chest pain
- chest exam often normal
- common extrapulmonary manifestations
  - eye involvement (anterior or posterior uveitis)
  - skin involvement (skin papules, erythema nodosum, lupus pernio)
  - peripheral lymphadenopathy
  - arthralgia
  - hepatomegaly ± splenomegaly
  - less common extra-pulmonary manifestations involve bone, CNS, kidney, cardiac (arrhythmias, sudden death, CHF)
- two acute sarcoid syndromes
  - Lofgren's syndrome: fever, erythema nodosum, bilateral hilar lymphadenopathy, arthralgias
  - Heerfordt-Waldenstrom syndrome: fever, parotid enlargement, anterior uveitis, facial nerve palsy

Investigations
- CBC (cytopenias from spleen or marrow involvement, lymphopenia common)
- serum electrolytes, creatinine, liver enzymes, calcium (hypercalcemia/hypercalciuria due to vitamin D activation by granulomas)
- hypergammaglobulinemia, occasionally RF positive
- elevated serum ACE (non-specific and non-sensitive) – reflects total body granuloma load
- CXR: predominantly nodular opacities especially in upper lung zones ± hilar adenopathy
- PFTs: normal, obstructive pattern, restrictive pattern with normal flow rates and decreased DL_{CO}, or mixed obstructive/restrictive pattern
- ECG: to rule out conduction abnormalities
- slit-lamp eye exam: to rule out uveitis

Diagnosis
- biopsy
  - transbronchial lung biopsy, transbronchial lymph node aspiration, EBUS guided surgical biopsy, or mediastinoscopic lymph node biopsy for granulomas
  - in ~75% of cases, transbronchial biopsy shows granulomas in the parenchyma even if the CXR is normal

Staging
- radiographic, based on CXR
  - Stage 0: normal radiograph
  - Stage I: bilateral hilar lymphadenopathy ± paratracheal lymphadenopathy
  - Stage II: bilateral hilar lymphadenopathy with pulmonary infiltration
  - Stage III: pulmonary infiltration alone (reticulonodular pattern or nodular pattern)
  - Stage IV: pulmonary fibrosis (loss of volume in upper lobes common, honeycombing uncommon)

Treatment
- observation if asymptomatic (85% of stage I resolve spontaneously within 2 yr, 50% of stage II resolve spontaneously within 5 yr)
- treatment for symptoms, declining lung function, hypercalcemia, or involvement of eye, CNS, kidney, or heart (not for abnormal CXR alone)
- first line treatment is prednisone
- methotrexate or other immunosuppressives can be used as an adjunct in case steroid response is unsatisfactory or as steroid-sparing agent in those who do not tolerate steroids
- lung transplant in end-stage disease

Remember to involve occupational health and place of work for data collection and treatment plan.
Also counsel re: worker's insurance as per jurisdiction (e.g. Workers Safety Insurance Board (WSIB) in Ontario)

Prognosis
- mortality ranges from less than 1% to 8% depending on care setting, severity of disease, and patient demographics (e.g. age, ethnicity, and sex)

PNEUMOCONIOSES
- group of chronic lung diseases caused by exposure to mineral dusts, and organic dusts
- no effective treatment, therefore key is exposure prevention through the reduction of dust and the use of protective equipment
- smoking cessation, annual influenza and pneumococcal vaccination, rehabilitation, lung transplant for endstage disease

Table 18. Pneumoconioses

Diagnosis	Etiology	Signs/Symptoms	Investigations	Complications
Asbestosis	Exposure risks: insulation, shipyard, construction, brake linings, pipe fitters, plumbers Slowly progressive diffuse interstitial fibrosis induced by inhaled asbestos fibres Usually requires >10-20 yr of exposure Latency period: 20-30 yr	Insidious onset Dyspnea Cough: paroxysmal, non-productive Clubbing (much more likely in asbestosis than silicosis or CWP)	CXR Lower > upper lobe Reticulonodular pattern, may develop IPF-like honeycombing Asbestos exposure can also cause pleural and diaphragmatic plaques (± calcification), pleural effusion, round atelectasis Microscopic examination reveals ferruginous bodies: yellow-brown rod-shaped structures which represent asbestos fibres coated in macrophages	Asbestos exposure increases risk of bronchogenic CA and malignant mesothelioma Risk of lung cancer dramatically increased for smokers
Silicosis	At risk population: sandblasters, rock miners, stone cutters, quarry and highway workers Generally requires >20 yr exposure; may develop with much shorter but heavier exposure	Dyspnea, cough, and wheezing	CXR Upper > lower lobe Early: nodular disease (simple pneumoconiosis), lung function usually normal Late: nodules coalesce into masses (progressive massive fibrosis) Possible hilar lymph node enlargement (frequently calcified), especially "eggshell" calcification	Mycobacterial infection (e.g. TB), chronic necrotizing aspergillosis, lung CA, rheumatic disorders, kidney disease, chronic airflow obstruction, and chronic bronchitis
Coal Workers' Pneumoconiosis	At risk population: coal workers, graphite workers, coal is less fibrogenic than silica	Simple CWP No signs or symptoms, usually normal lung function Complicated CWP (also known as progressive massive fibrosis) Dyspnea course: few patients progress to complicated CWP	Simple CWP CXR: multiple nodular opacities, mostly upper lobe Pathologic hallmark is coal macule Complicated CWP CXR: opacities larger and coalesce	COPD, chronic renal failure, rheumatoid arthritis

INTERSTITIAL LUNG DISEASE ASSOCIATED WITH DRUGS OR TREATMENTS

Drug-Induced
- antineoplastic agents: bleomycin, mitomycin, busulfan, cyclophosphamide, methotrexate, chlorambucil, BCNU (carmustine)
- antibiotics: nitrofurantoin, penicillin, sulfonamide
- cardiovascular drugs: amiodarone, tocainide
- anti-inflammatory agents: methotrexate, penicillamine, etanercept, gold salts
- recreational drugs (heroin, methadone)
- biologics: rituximab, anti-TNF-α agents (infliximab, etanercept, adalimumab), immunotherapy drugs

Radiation-Induced
- acute pneumonitis: typically 4-12 wk post-exposure
- late fibrosis: 6-12 mo post-exposure
- infiltrates conform to the shape of the radiation field

Pulmonary Vascular Disease

Pulmonary Hypertension

Definition
- mean pulmonary arterial pressure >20 mmHg with a peripheral vascular resistance (PVR) ≥3 Wood units measured by right heart catheterization in supine position at rest
- pulmonary HTN is grouped into 5 categories and classified based on etiology

Table 19. World Health Organization Classification of Pulmonary Hypertension and their Treatment Options

Classification	Some Causes	Treatment Options	Consider in All Patients with PH
I. Pulmonary Arterial HTN (PAH)	Idiopathic Hereditary mutations Collagen vascular disease (scleroderma, SLE, RA) Congenital heart disease (Eisenmenger syndrome) Persistent pulmonary hypertension of the newborn (PPHN) Portopulmonary HTN HIV infection Drugs and toxins (e.g. anorexigens) Schistosomiasis Pulmonary capillary hemangiomatosis Pulmonary veno-occlusive disease (PVOD)	CCBs for patients with vasoreactivity. Advanced therapy with single or combination prostanoids, endothelin receptor antagonists (ERA), PDE5 inhibitors. Lung transplantation for refractory advanced patients. Treatment of underlying condition if relevant	Oxygen therapy Exercise Consider anticoagulation Influenza and pneumococcal vaccines Counselling on pregnancy risks Diuretic therapy in patients with signs of right ventricular failure and fluid retention
II. Pulmonary HTN due to Left Heart Disease	Related to heart failure with preserved ejection fraction (HFpEF) or heart failure with reduced ejection fraction (HFrEF) Left-sided valvular heart disease (e.g. aortic stenosis, mitral stenosis) Congenital/acquired left heart inflow/outflow tract obstruction and congenital cardiomyopathies	Treat underlying heart disease Group I PH (PAH) therapies not applicable in Group II PH	
III. Pulmonary HTN due to Lung Disease and/or Hypoxia	Obstructive lung disease (COPD) Restrictive lung disease (e.g. interstitial lung disease like idiopathic pulmonary fibrosis) Mixed restrictive/obstructive lung disease (e.g. lymphangioleiomyomatosis) Chronic alveolar hypoxia (chronic high altitude, alveolar hypoventilation disorders, sleep-disordered breathing, developmental lung disorders)	Treat underlying lung disease and/or cause of chronic hypoxia and correct with supplemental oxygen (proven mortality benefit) Group I PH (PAH) therapies not applicable in Group III PH	
IV. Chronic Thromboembolic Pulmonary HTN (CTEPH)	Chronic PE, other pulmonary artery obstruction (e.g. tumours, parasites, congenital stenosis) Thromboembolic obstruction of proximal pulmonary arteries	Anticoagulation, pulmonary thromboendarterectomy, riociguat	
V. Pulmonary HTN with Unclear Multifactorial Mechanisms	Hematologic disorders (e.g. sickle cell) Systemic disorders (e.g. sarcoidosis) Metabolic disorders Extrinsic compression of central pulmonary veins (tumour, adenopathy, fibrosing mediastinitis) Segmental pulmonary hypertension	Treat underlying cause	

Adapted: Simonneau G, Montani D, Celermajer DS, et al. Haemodynamic definitions and updated clinical classifications of pulmonary hypertension. Eur Respir J 2019;53;1801913. Table 2

IDIOPATHIC PULMONARY ARTERIAL HYPERTENSION (PRIMARY PULMONARY HYPERTENSION)

Definition
- pulmonary HTN in the absence of a demonstrable cause (i.e. Group I)
- disease of the pulmonary artery vessel wall characterized by vasoconstriction, vascular proliferation, and obstructive remodeling leading to increased pulmonary vascular resistance

Pathology
- histology includes medial arterial hypertrophy, intimal fibrosis, and plexiform arteriopathy

Epidemiology
- usually older adults between the ages of 50 and 65, female predominance at younger ages
- most cases are sporadic; familial predisposition in <5% of cases, some linked to mutations in BMPR2

Signs and Symptoms

Table 20. Signs and Symptoms of Pulmonary Hypertension

Symptoms	Signs
Dyspnea	Loud, palpable P2
Fatigue	RV heave
Retrosternal chest pain	Right-sided S4 (due to RVH)
Syncope	Systolic murmur (tricuspid regurgitation (TR))
Symptoms of underlying disease	If right ventricular failure: right sided S3, increased JVP, positive hepatojugular reflux, peripheral edema, TR
Peripheral Edema	Signs of underlying disease
Palpitations	

*Physical exam may be unremarkable in early disease

Diagnosis
- exclude:
  - left heart disease
  - lung disease
  - chronic thromboembolic disease
  - diseases in Group V PH
  - known causes of Group I PAH
    - connective tissue diseases
    - drugs/toxins
    - congenital heart disease
    - HIV
    - schistosomiasis
    - liver disease
    - heritable disease
    - PVOD/pulmonary capillary hemangiomatosis (PCH)

Investigations
- CXR: enlarged central pulmonary arteries, cardiac changes due to right ventricular enlargement (filling of retrosternal air space)
- ECG: RVH/right-sided strain (see Cardiology and Cardiac Surgery, C7)
- 2-D echo doppler assessment of right ventricular systolic pressure
- right heart catheterization: to confirm diagnosis through direct measurement of mean pulmonary arterial pressure, pulmonary capillary wedge pressure, pulmonary vascular resistance, and cardiac output
- PFTs to assess for underlying lung disease: DL_{CO} usually reduced; volumes and flows normal
- CT angiogram to assess lung parenchyma and possible PE
- V/Q scan ± pulmonary angiogram to rule out thromboembolic disease
- serology: ANA positive in 30% of patients with primary pulmonary HTN; other serologic markers can be used in the appropriate clinical setting
- routine blood work: biochemistry, CBC, TSH, liver function tests, possible HIV test

Treatment
- treatment depends on classification (see Table 19, R18)

Prognosis
- morbidity and mortality are high but depend on underlying condition
- survival decreases to approximately 1 yr if severe pulmonary HTN (with rapid progression of symptoms, frequent syncope, and advanced WHO functional class), or right heart failure

Guidelines for Vasodilator Response in Pulmonary Arterial HTN
- Patients with idiopathic pulmonary arterial hypertension (IPAH) that respond to vasodilators acutely, have an improved survival with long-term use of CCBs
- Vasoreactivity testing: short-acting agent such as IV epoprostenol, IV adenosine, or inhaled NO
- Positive vasodilator response: mean pulmonary artery pressure (PAP) fall of at least 10 mmHg to ≤40 mmHg with an increased or unchanged cardiac output (European Society of Cardiology)
- Positive vasodilator response: should be considered as candidate for trial of oral CCB therapy

Medical Therapy for Pulmonary Arterial Hypertension. ACCP Evidence-Based Clinical Practice Guidelines. Chest 2004;(Suppl)06:126

Pulmonary arterial pressures are measured by pulmonary artery catheters (i.e. Swan-Ganz catheter) which are inserted into a large vein (often internal jugular). A balloon at the end of the catheter tip is inflated causing the catheter to advance through the right side of the heart and into the pulmonary artery. This allows for the measurement of right atrial, right ventricular, pulmonary artery, and pulmonary capillary wedge pressures as well as sampling of mixed venous blood. A thermistor near the end of the catheter also allows for assessment of cardiac output by thermodilution

Virchow's Triad
- Venous stasis
- Endothelial cell damage
- Hypercoagulable states

Pulmonary Embolism

Definition
- mechanical obstruction of the pulmonary vasculature leading to obstruction of blood flow
- can be classified as acute, subacute, or chronic depending on presentation of symptoms relative to time after initial event
  - an acute PE can also be classified as massive, sub-massive, and low-risk PE

Etiology and Pathophysiology
- lower extremity deep vein thrombi are the source of most clinically recognized PEs
- less common causes include fat emboli, septic emboli, amniotic fluid emboli, tumour thrombi, and air emboli
- thrombi often start in calf, but must propagate into proximal veins to create a sufficiently large thrombus for a clinically significant PE

Epidemiology
- one of the most common causes of preventable death in the hospital
- VTE affects approximately 1-2 in 1000 adults per yr with approximately one third of first VTE presentations being due to PE

Risk Factors
- stasis
  - immobilization: paralysis, stroke, bed rest, prolonged sitting during travel, immobilization of an extremity after fracture
  - obesity, CHF
  - chronic venous insufficiency
- endothelial cell damage
  - postoperative injury, trauma
- hypercoagulable states
  - underlying malignancy (particularly adenocarcinoma)
  - CA treatment (chemotherapy, hormonal)
  - exogenous estrogen administration (oral contraceptive pill, hormone replacement therapy)
  - pregnancy, post-partum
  - prior history of DVT/PE, family history
  - nephrotic syndrome
  - coagulopathies: Factor V Leiden, Prothrombin 20210A variant, inherited deficiencies of antithrombin/protein C/protein S, antiphospholipid antibody, hyperhomocysteinemia, increased Factor VIII levels, and myeloproliferative disease
- increasing age

Investigations (if highly suspicious, go straight to CT pulmonary angiogram)
- see Emergency Medicine, ER33

Table 21. Common Investigations for Pulmonary Embolism

Investigation	Purpose/Utility
Pulmonary Angiography (Gold Standard)	Filling defect indicative of embolus; negative angiogram excludes clinically relevant PE
	More invasive, and harder to perform than CT, therefore done infrequently
D-Dimer	Highly sensitive D-dimer result can exclude DVT/PE if pretest probability is already low
	Little value if pretest probability is high
	If D-dimer positive, will need further evaluation with compression U/S (for DVT) and/or CT (for PE)
CT Angiogram	Both sensitive and specific for PE
	Diagnosis and management uncertain for small filling defects
	CT may identify an alternative diagnosis if PE is not present
	CT scanning of the proximal leg and pelvic veins can be done at the same time and may be helpful
Venous Duplex U/S or Doppler	With leg symptoms
	Positive test rules in proximal DVT
	Negative test rules out proximal DVT
	Without leg symptoms
	Positive test rules in proximal DVT
	Negative test does not rule out a DVT: patient may have non-occlusive or calf DVT
ECG	Findings not sensitive or specific
	Sinus tachycardia most common; may see non-specific ST segment and T wave changes
	RV strain, RAD, right bundle branch block (RBBB), S1-Q3-T3 with massive embolization

Multidetector Computed Tomography for Acute Pulmonary Embolism (PIOPED II Trial)
NEJM 2006;354:2317-2327
Study: Multicentre, prospective study
Population: 824 patients with clinically suspected acute PE
Measurements: Accuracy of multidetector CTA alone and combined with venous-phase imaging.
Outcomes: Diagnosis of PE.
Results: 773 of 824 patients had adequate CTAs for interpretation. PE was diagnosed in 192 of the 824 patients. Sensitivity was 83% (150 of 181 patients, 95% CI 0.76-0.92) and specificity was 96% (567 of 592 patients, 95% CI 0.93-0.97). However, the predictive value of CTA-CTV varied when clinical pre-test probability was taken into account. PPV of CTA for high, intermediate and low clinical probability were 96% (95% CI 0.78-0.99), 92% (95% CI 0.84-0.96), and 58% (95% CI 0.40-0.73), respectively. NPV of CTA for high, intermediate, and low clinical probability were 60% (95% CI 0.32-0.83), 89% (95% CI 0.82-0.93), and 96% (95% CI 0.92-0.98) respectively.
Conclusion: CTA is effective for diagnosing or excluding PE in accordance with assessment of clinical pretest probability. When clinical probability is inconsistent with imaging results, further investigations are required to rule out PE.

D-dimer is elevated in patients with increased age, recent surgery, CA, inflammation, infection, pregnancy, and severe renal dysfunction. It has good sensitivity and negative predictive value, but poor specificity and positive predictive value

Classic ECG finding of PE is S1-Q3-T3 (inverted T3), but most commonly only sinus tachycardia is seen

Clinical Prediction Rule for Pulmonary Embolism
J Thromb Hemost 2000;83:416-420

Wells' Criteria

Risk Factors	Points
Clinical signs of DVT	3.0
No more likely alternative diagnosis	3.0
Immobilization or surgery in previous 4 wk	1.5
Previous PE/DVT	1.5
HR >100 beats/min	1.5
Hemoptysis	1.0
Malignancy	1.0
Clinical Probability	
Low (0-2)	3%
Intermediate (3-6)	28%
High (>6)	78%

Modified Wells': >4 PE likely; ≤4 PE unlikely
JAMA 2006

Table 21. Common Investigations for Pulmonary Embolism

Investigation	Purpose/Utility
CXR	Frequently normal; no specific features
	Atelectasis (subsegmental), elevation of a hemidiaphragm
	Pleural effusion: usually small
	Hampton's hump: cone-shaped area of peripheral opacification representing infarction
	Westermark's sign: dilated proximal pulmonary artery with distal oligemia/decreased vascular markings (difficult to assess without prior films)
	Dilatation of proximal pulmonary artery: rare
V/Q Scan	Very sensitive but low specificity
	Order scan if:
	CXR normal, no COPD
	Contraindication to CT (contrast allergy, renal dysfunction, pregnancy)
	Avoid V/Q scan if:
	CXR abnormal or COPD
	Inpatient
	Suspect massive PE
	Results:
	Normal: excludes the diagnosis of PE
	High probability: most likely means PE present, unless pre-test probability is low
	60% of V/Q scans are nondiagnostic
Echocardiogram	Useful to assess massive or chronic PE
	Dependent on clinical status
ABG	No diagnostic use in PE (insensitive and nonspecific)
	May show respiratory alkalosis (due to hyperventilation)

Treatment

- admit for observation and stratify risk – in low-risk PE setting with no other indication for hospitalization and low-risk of early adverse outcomes, patients may be sent home with anticoagulation
- oxygen: supplemental oxygen should be administered to target an oxygen saturation ≥90 percent
- pain relief: analgesics if chest pain – narcotics or acetaminophen
- acute anticoagulation: therapeutic-dose SC LMWH or fondaparinux or unfractionated heparin or oral factor Xa inhibitors (rivaroxaban, apixaban, edoxaban) or direct thrombin inhibitors (dabigatran) – start ASAP
  - anticoagulation stops clot propagation, prevents new clots, and allows endogenous fibrinolytic system to dissolve existing thromboemboli over months; get baseline CBC, INR, aPTT ± renal function ± liver function
  - for SC LMWH: dalteparin 200 U/kg once daily, enoxaparin 1 mg/kg BID, or fondaparinux 5-10 mg once daily – no lab monitoring – avoid or reduce dose in renal dysfunction
  - for IV heparin: bolus of 75 U/kg (usually 5000 U) followed by infusion starting at 20 U/kg/h – aim for aPTT 2-3x control
- long-term anticoagulation
  - for most nonpregnant patients who do not have renal insufficiency or active cancer, first-line is direct oral anticoagulants (rivaroxaban, apixaban, edoxaban, or dabigatran) rather than warfarin
  - if using warfarin instead of DOAC: start the same day as LMWH/heparin – overlap warfarin with LMWH/heparin for at least 5 d and until INR in target range of 2-3 for at least 2 d (use for patients with severe renal insufficiency)
  - LMWH instead of warfarin for pregnancy, active cancer, or high bleeding risk patients
- IV thrombolytic therapy
  - if patient has massive PE (hypotension or clinical right heart failure) and no contraindications
  - hastens resolution of PE but may not improve survival or long-term outcome and doubles risk of major bleeding
  - interventional thrombolytic therapy
  - massive PE may be treated with catheter-directed thrombolysis by an interventional radiologist
  - catheter-directed thrombolysis is not recommended over systemic thrombolysis
- IVC filter: routine use is not indicated if recent proximal DVT + absolute contraindication to anticoagulation
- duration of long-term anticoagulation: individualized, however generally
  - if reversible cause for PE (surgery, injury, pregnancy, etc.): 3-6 mo
  - if PE unprovoked: 6 mo to indefinite
  - if ongoing major risk factor (active cancer, antiphospholipid antibody, etc.): indefinite

PE Rule Out Criteria (PERC)
Prospective Multicentre Evaluation of the Pulmonary Embolism Rule Out Criteria
J Thromb Hemost 2008;6:772
- Age less than 50 yr
- Heart rate less than 100 bpm
- Oxyhemoglobin saturation ≥95 percent
- No hemoptysis
- No estrogen use
- No prior DVT or PE
- No unilateral leg swelling
- No surgery or trauma requiring hospitalization within the past 4 wk

Acute PE can probably be excluded without further diagnostic testing if the patient meets all PERC criteria AND there is a low clinical suspicion for PE, according to either the Wells' criteria or a low gestalt probability determined by the clinician prior to diagnostic testing for PE.

Evaluation of a Suspected Pulmonary Embolism
LOW CLINICAL PROBABILITY OF EMBOLISM
D-dimer (+ve) → CT scan (+ve) → ruled in
(–ve) → ruled out
Intermediate or high probability
CT pulmonary angiography scan
(–ve) → ruled out
(+ve) → ruled in

Notes:
- Use D-dimers only if low clinical probability, otherwise, go straight to CT
- If using V/Q scans (CT contrast allergy or renal failure):
  - Negative V/Q scan rules out the diagnosis
  - High probability V/Q scan only rules in the diagnosis if high clinical suspicion
  - Inconclusive V/Q scan requires leg U/S to look for DVT or CT

Workup for Idiopathic Venous Thromboembolism
Thrombophilia workup: recurrent or idiopathic DVT/PE, age <50, FMHx, unusual location, massive
Malignancy workup: 12% of patients with idiopathic VTE will have a malignancy

The Use of Unfractionated Heparin Should Be Limited to:
- Patients with severe renal dysfunction (CrCl <30 ml/min) in whom LMWH and novel oral anticoagulation should be avoided
- Patients at elevated risk of bleeding that may need rapid reversal of anticoagulation
- Patients who receive thrombolytic therapy

See Landmark 10M Respirology Trials table for more information on EPSTEIN-CHOICE which details the efficacy of rivaroxaban vs. ASA in patients with VTE who completed a 6-12 mo course of anticoagulation therapy.

Thromboprophylaxis

- mandatory for most hospital patients: reduces DVT, PE, all-cause mortality, cost-effective
- start ASAP
- continue at at least until discharge or recommend extending for 35 d postoperatively, if major orthopaedic surgery

Table 22. VTE Risk Categories and Prophylaxis (see Hematology, H36)

Risk Group	Prophylaxis Options
Low Thrombosis Risk	
Medical patients: fully mobile	No specific prophylaxis
Surgery: <30 min, fully mobile	Frequent ambulation
Moderate Thrombosis Risk	
Most general, gynaecologic, urologic surgery	LMWH
Sick medical patients	Low dose unfractionated heparin
	Fondaparinux
High Thrombosis Risk	
Arthroplasty, hip fracture surgery	LMWH
Major trauma, spinal cord injury	Fondaparinux
	Warfarin (INR 2-3)
	Dabigatran
	Apixaban
	Rivaroxaban
	Low dose unfractionated heparin
High Bleeding Risk	
Neurosurgery, intracranial bleed	TED stockings™, pneumatic compression devices
Active bleeding	LMWH or low dose heparin when bleeding risk decreases

Direct Oral Anticoagulants Compared with Vitamin K Antagonists (VKAs) for Acute Venous Thromboembolism: Evidence from Phase 3 Trials
Blood 2014;124:1968-1975
Study: Meta-analysis of six phase 3 randomized controlled trials
Population: 27023 patients with VTE
Intervention: DOACs versus VKAs
Outcomes: Overall efficacy, safety profile, and net clinical benefit for the treatment of acute symptomatic VTE
Results: Recurrent VTE occurred in 2.0% of DOAC recipients compared with 2.2% in VKA recipients (RR 0.90, 95% CI 0.77-1.06). Treatment with a DOAC significantly reduced the risk of major bleeding (RR 0.61, 95% CI 0.45-0.83).
Conclusions: DOACs and VKAs have a similar efficacy in the treatment of acute symptomatic VTE; however, treatment with a DOAC significantly reduces the risks of major bleeding.

Scleroderma is the most likely collagen vascular disease to lead to pulmonary involvement, which can include ILD and pulmonary HTN

Horner's Syndrome
Ptosis, Miosis, Anhidrosis

Pulmonary Vasculitis

Table 23. Pulmonary Vasculitis

Disease	Definition	Pulmonary Features	Extra Pulmonary Features	Investigations	Treatment
Granulomatosis with Polyangiitis (GPA, previously Wegener's Granulomatosis) (see Nephrology, NP25, NP26, NP29)	Systemic vasculitis of medium and small arteries, most common pulmonary vasculitis	Necrotizing granulomatous lesions of the respiratory tract, which may lead to tracheal and/or bronchial stenosis, nodules, ILD, or alveolar hemorrhage	Focal necrotizing lesions of arteries and veins; may have nasal, sinus, and ear disease; crescentic glomerulonephritis	CXR/CT: nodules, cavities, and alveolar opacities c-ANCA (positive in 90% of cases) PR3 Tissue confirmation Urinalysis: look for abnormal sedimentation	Corticosteroids and cyclophosphamide or rituximab Plasma Exchange (PLEX) is also used often in cases of pulmonary hemorrhage, severe renal failure, or concomitant anti-GBM Prognosis with treatment is generally good (65-90% achieve full remission)
Eosinophilic Granulomatosis with Polyangiitis (EGPA, Churg-Strauss)	Multisystem disorder characterized by allergic rhinitis, asthma, and prominent peripheral eosinophilia	Asthma (prodromal phase, usually occurs before other systemic features) Eosinophilic infiltrates in small-and- medium sized vessels	Life-threatening systemic vasculitis involving the lungs, pericardium and heart, kidneys, skin, and PNS (mononeuritis multiplex)	CXR can often be normal (30-60%) but can see transient, patchy opacities Peripheral eosinophilia is the most common finding p-ANCA, myeloperoxidase (MPO) may be positive Biopsy involved tissue	Corticosteroids Cyclophosphamide (Use Five Factor Score to determine need) With treatment, 90% of patients have clinical remission
Anti-GBM Disease (Goodpasture's) (see Nephrology, NP24)	A disorder characterized by diffuse alveolar hemorrhage and glomerulonephritis caused by anti-GBM antibodies, which cross-react with basement membranes of the kidney and lung	Alveolar hemorrhage, which may present with dyspnea, cough, hemoptysis May follow influenza infection	Anemia Acute renal failure	CXR: may see alveolar infiltrates ELISA test with anti-GBM antibodies Renal biopsy/indirect immunofluorescence shows linear staining	Acutely: corticosteroids, plasmapheresis, immunosuppressive therapy Severe cases: bilateral nephrectomy
Systemic Lupus Erythematosus, Rheumatoid Arthritis, Scleroderma	See Rheumatology, RH11, RH9, and RH15				

Pulmonary Edema

- see Cardiology and Cardiac Surgery, C42

Diseases of the Mediastinum and Pleura

Mediastinal Masses

- see General and Thoracic Surgery, GS13

Mediastinitis

- most common causes: postoperative complications of cardiovascular or thoracic surgical procedures

Acute

- etiology
  - perforation of esophagus or trachea – vomiting (Boerhaave's syndrome), penetrating trauma, foreign body, instrumentation, erosion (e.g. carcinoma, infection)
  - direct extension of infection – dental, lung, pleura, pericardium, lymph nodes, paraspinous, pancreatic
  - postoperative (sternotomy or mediastinoscopy)
  - primary mediastinal infections (e.g. inhalational anthrax)
- signs and symptoms
  - fever, substernal pain; often a dramatic and acute onset of symptoms, with irritability, restlessness, and a sense of impending doom
  - pneumomediastinum, mediastinal compression
  - Hamman's sign (auscultatory "crunch" during cardiac systole)
- treatment
  - antibiotics (IV vancomycin + 3rd gen cephalosporin), drainage, ± surgical closure of perforation

Pleural Effusions

Definition

- excess amount of fluid in the pleural space

Etiology

- disruption of normal equilibrium between pleural fluid formation/entry and/or pleural fluid absorption/exit
- pleural effusions are classified as transudative or exudative
  - distinguish clinically using Light's Criteria (98% sensitivity and 83% specificity for identifying exudative pleural effusions)

Table 24. Laboratory Values in Exudative Pleural Effusion

	Light's Criteria	Modified Light's Criteria
Protein – Pleural/Serum	>0.5	>0.5
LDH – Pleural/Serum	>0.6	>0.6
Pleural LDH	>2/3 upper limit of N serum LDH	>0.45 upper limit of N serum LDH
Exudate = any one criterion		

Ann Intern Med 1979;77:507-513
Chest 1997;111:970-980

Transudative Pleural Effusions

- pathophysiology: alterations to Starling forces affects the rates of formation and absorption of pleural fluid
- etiology
  - CHF: usually bilateral, right-sided more than the left, can occasionally be isolated right-sided
  - cirrhosis leading to hepatic hydrothorax
  - nephrotic syndrome, protein losing enteropathy
  - pulmonary embolism (may cause transudative but more often causes exudative effusion)
  - peritoneal dialysis with transdiaphragmatic flow, hypothyroidism, CF, urinothorax

Exudative Pleural Effusions

- pathophysiology: increased permeability of pleural capillaries or lymphatic dysfunction

Differential of an Anterior Compartment Mass

4 Ts
Thymoma
Thyroid enlargement (goitre)
Teratoma
Tumours (lymphoma, parathyroid, esophageal, angiomatous

Mediastinal Components

- **Anterior**: sternum to pericardium and great vessels. Includes: thymus, extrapericardial aorta and branches, great veins, lymphatic tissues
- **Middle**: pericardium (anteriorly), posterior pericardial reflection, diaphragm, thoracic inlet. Includes: heart, intrapericardial great vessels, pericardium, trachea
- **Posterior**: posterior pericardial reflection, posterior border of vertebral bodies, first rib to the diaphragm. Includes: esophagus, vagus nerve, thoracic duct, sympathetic chain, azygous venous system

Starling's hypothesis: The rate of passive fluid movement across a capillary wall is governed by the gradients of hydrostatic pressure and oncotic pressure across the same capillary wall

Transudative effusions are usually bilateral, not unilateral

Exudative effusions can be bilateral or unilateral

Table 25. Exudative Pleural Effusion Etiologies

Etiology	Examples
Infectious	Parapneumonic effusion (associated with bacterial pneumonia, or other process such as lung abscess)
	Empyema: bacterial, fungal, TB
	TB pleuritis
	Viral infection (rare)
	Fungal
	Parasitic
Malignancy	Lung carcinoma (35%)
	Lymphoma (10%)
	Metastases: breast (25%), ovary, kidney
	Mesothelioma
	Myeloma
Inflammatory	Collagen vascular diseases: RA, SLE
	Pancreatitis
	Benign asbestos related effusion
	Pulmonary embolism
	Artificial rupture of membranes
	Post-coronary artery bypass grafting or cardiac injury
	Drug reaction
Intra-Abdominal	Subphrenic abscess
	Pancreatic pseudocyst with fistula into pleural space (associated with elevated pleural fluid amylase)
	Meigs' syndrome (ascites and hydrothorax associated with an ovarian fibroma or other pelvic tumour) (can also be a transudate)
Intra-Thoracic	Esophageal perforation (associated with elevated pleural fluid amylase)
Trauma	Hemothorax: rupture of a blood vessel, commonly by trauma or tumours
	Pneumothorax: spontaneous, traumatic
	Chylothorax
	Iatrogenic
Other	Drug-induced
	Hypothyroidism (can also be transudate)

Appearance of Pleural Fluid
- Bloody: trauma, malignancy, traumatic tap
- White: empyema, chylous, or chyliform effusion
- Black: aspergillosis, amoebic liver abscess
- Yellow-green: rheumatoid pleurisy
- Viscous: malignant mesothelioma
- Ammonia odour: urinothorax
- Food particles: esophageal rupture

Signs and Symptoms
- often asymptomatic
- dyspnea: varies with size of effusion and underlying lung function
- pleuritic chest pain, shoulder pain (referred pain due to phrenic nerve, from C3-C5, innervating the diaphragm)
- inspection: when accumulated rapidly trachea can deviates away from effusion, ipsilateral decreased expansion
- palpation: decreased tactile fremitus
- percussion: dullness
- auscultation: decreased breath sounds, bronchial breathing and egophony above fluid level, sometimes pleural friction rub if inflammatory cause and minimal fluid

Investigations
- CXR
  - dense opacification of lung fields with concave meniscus
  - must have >200 mL of pleural fluid for visualization on PA film
  - PA: blunting of lateral costophrenic angle
  - lateral: >50 mL leads to blunting of posterior costophrenic angle
  - decubitus: fluid will layer out unless it is loculated
  - supine: fluid will appear as general haziness over lung field
- CT: helpful in differentiating parenchymal from pleural abnormalities; identifying loculation, measuring density of fluid (higher density may indicate a hemothorax); contrast can detect pleural enhancement indicative of empyema and may identify underlying lung pathology causing effusion
- U/S: detects small effusions and can guide thoracentesis
- thoracentesis: indicated if pleural effusion is a new and concerning finding; order blood work (serum LDH, glucose, protein) at the same time for comparison
  - risk of re-expansion pulmonary edema if >1.5 L of fluid is removed in one shot
  - inspect for colour, character, presence of pus, and odour of fluid
  - send fluid for analysis (see Table 26, R25)
- pleural biopsy: indicated if suspect TB, mesothelioma, or other malignancy (and if cytology negative)

Role of CT in Pleural Effusion
- To assess for fluid loculation, pleural enhancement, thickening and nodules, parenchymal abnormalities, and adenopathy
- Can provide clues to help distinguish benign from malignant effusion
- May not distinguish empyema from parapneumonic effusion

Features of Malignant Effusion
- Multiple pleural nodules
- Circumferential pleural thickening
- Thickening >1 cm
- Mediastinal pleural involvement

Imaging Features of Empyema
- Parietal pleural thickening
- Pleural enhancement
- Concurrent thickening and enhancement of both the visceral and parietal pleural (split pleural sign)

Table 26. Analysis of Pleural Effusion

Measure	Purpose
Always order:	
Protein, LDH	Transudate vs. exudate
	LDH especially high (>1000 IU/L) in empyema, rheumatoid, malignancy
	Protein especially high in TB, myeloma
Gram Stain, Ziehl-Neelsen Stain (TB), Culture	Looking for specific organisms (can add Ziehl-Neelsen Stain if TB suspected)
Cell Count Differential	Neutrophils vs. lymphocytes (lymphocytic effusion in TB, cancer, lymphoma, RA) Eosinophilic (seen in pneumothorax, hemothorax, drug reactions, pulmonary embolism, eosinophilic granulomatosis with polyangiitis, asbestos-related, malignancy, parasitic, occasionally TB) High RBC count: mostly traumatic, malignancy, PE with infarction, TB, hemothorax
Cytology	Malignancy, infection
Glucose	Low (fluid:serum <0.5) in rheumatoid, TB, empyema, malignancy, esophageal rupture
pH	Normally about 7.6
	Very low (<7.0) in empyema, TB, rheumatoid, malignancy, esophageal rupture
May order (depending on clinical suspicion):	
Albumin	Albumin gradient for higher specificity assessment for exudate (compared to Light's criteria alone)
Amylase	Pancreatitis, esophageal perforation, malignancy
Rheumatoid Factor, ANA, Complement	Collagen vascular disease
Triglycerides	Chylothorax from thoracic duct leakage, mostly due to trauma, lung CA, or lymphoma
Cholesterol, chylomicrons	Distinguish between chylothorax and chyliform effusion (latter seen in inflammation, e.g. TB, RA)

Complicated Parapneumonic Effusion (needs drainage if any of these are present):
pH ≤7.2
Glucose ≤2.2 mmol/L
LDH ≥1000
Gram stain or culture positive
Loculated
No frank pus

Empyema (always needs drainage)
Frank pus on tap
May or may not be loculated, and will often fulfill many of the criteria of a Complicated Parapneumonic Effusion

Treatment
- thoracentesis
- treat underlying cause
- consider indwelling pleural catheter or pleurodesis in refractory effusions
- consultation with thoracic surgery for potential surgical management

When possible, organism-directed therapy, guided by culture sensitivities or local patterns of drug resistance, should be utilized

Complicated Parapneumonic Effusion

- see General and Thoracic Surgery, GS18

Empyema

- see General and Thoracic Surgery, GS18

Atelectasis

- see General and Thoracic Surgery, GS11

Pneumothorax

- see General and Thoracic Surgery, GS19

Asbestos-Related Pleural Disease

Etiology and Pathophysiology
- non-malignant manifestations of asbestos exposure:
  - benign asbestos pleural effusion (BAPE)
  - exudative effusion, typically ~10 yr after exposure, often resolves on its own
  - pleural cytology is needed to distinguish this from mesothelioma or pleural extension of other malignancies
  - asbestosis
  - lower lobe interstitial lung disease (appears same as idiopathic pulmonary fibrosis)
  - round atelectasis
  - commonly seen peripherally, due to asbestos-pleural disease
  - calcified pleural plaques or pleural thickening
  - marker of exposure; usually an asymptomatic radiologic finding

Need to Rule Out Life-Threatening Tension Pneumothorax
If pneumothorax with:
- Severe respiratory distress
- Tracheal deviation to contralateral side
- Distended neck veins (↑ JVP)
- Signs of hemodynamic instability (e.g. hypotension)

Do not perform CXR
Needs immediate treatment
See Emergency Medicine, ER11 and ER22

Mesothelioma

Etiology and Pathophysiology
- primary malignancy of the pleura
- decades after asbestos exposure (even with limited exposure)
- smoking not a risk factor, but asbestos and smoking synergistically increase risk of lung cancer

Signs and Symptoms
- persistent chest pain, dyspnea, cough, bloody pleural effusion, and weight loss
- there can be associated paraneoplastic syndromes (e.g. hypercalcemia, hemolytic anemia, hypoglycemia)

Investigations
- biopsy (pleuroscopic or open)
- needle biopsy may seed needle tract with tumour
- CT thorax

Treatment
- use of multidisciplinary team with trimodal treatment (e.g. chemotherapy, radiation, surgical resection)
- palliation is often needed because of poor prognosis

Respiratory Failure

Definition
- failure of respiratory system to maintain normal blood gases
- hypoxemic (PaO_2 <60 mmHg), hypercapnic ($PaCO_2$ >50 mmHg)
- acute vs. chronic (compensatory mechanisms activated)

Signs and Symptoms
- signs of underlying disease
- hypoxemia: restlessness, confusion, cyanosis, coma, cor pulmonale
- hypercapnia: headache, dyspnea, drowsiness, asterixis, warm periphery, plethora, increased ICP (secondary to vasodilatation)

Investigations
- ABGs
- CXR and/or CT
- pulmonary function tests (for chronic respiratory failure)

Hypoxemic Respiratory Failure

Definition
- PaO_2 decreased, $PaCO_2$ normal or decreased

Treatment
- reverse the underlying pathology
- oxygen therapy: maintain oxygenation (if shunt present, supplemental O_2 is less effective
  - see Anesthesia, A10, for oxygen delivery systems)
- ventilation, BiPAP, and PEEP/CPAP (see Anesthesia, A11): positive pressure can recruit alveoli and redistribute lung fluid
- improve cardiac output: ± hemodynamic support (fluids, vasopressors, inotropes) (increases O_2 delivery), reduces O_2 requirements

Table 27. Approach to Hypoxemia

Type of Hypoxemia	Settings	$PaCO_2$	$A\text{-}aO_2$	Oxygen Therapy	Ventilation, BiPAP, and PEEP	Increasing Cardiac Output
1. Low FiO_2	High altitude	N or ↓	N	Improves	No change	No change
2. Hypoventilation	Drug overdose, obesity, hypoventilation syndrome	↑	N	Improves	Improves with ventilation	No change
3. Physiologic Shunt = V/Q mismatch with low V	ARDS, pneumonia	N or ↓	↑	Less effective	Improves	No change
4. Anatomic Shunt (Right to Left)	Ventricular septal defect	N or ↓	↑	No change	Can worsen by increasing shunt	Can worsen
5. Low Mixed Venous O_2 Content	Shock	↓	↑	Improves or no change	Can worsen by reducing cardiac output	Improves
6. Diffusion Impairment	ILD, emphysema	N	↑	Improves	Improves with positive pressure	No change or worsens

*Where "N" = within normal limits
Reprinted with permission from Dr. Ian Fraser

Hypercapnic Respiratory Failure

Definition

- $PaCO_2$ increased, PaO_2 decreased

Pathophysiology

- increased CO_2 production: fever, sepsis, seizure, acidosis, carbohydrate load
- increased dead space (normal or increased minute ventilation, low alveolar ventilation): COPD, CF, chest wall disorder, dead space ventilation (rapid shallow breathing)
  - inefficient gas exchange results in inadequate CO_2 removal in spite of normal or increased minute volume
- hypoventilation (low minute ventilation)
  - restrictive process such as chest wall disorder (e.g. severe kyphoscoliosis)
  - central: brainstem stroke, hypothyroidism, severe metabolic alkalosis, drugs (opiates, benzodiazepines)
  - neuromuscular: myasthenia gravis, Guillain-Barré, phrenic nerve injury, muscular dystrophy, polymyositis
  - muscle fatigue

Treatment

- reverse the underlying pathology
- if $PaCO_2$ >50 mmHg and pH <7.35 consider noninvasive or mechanical ventilation
- correct exacerbating factors
  - nasotracheal/endotracheal tube suction: clearance of secretions
  - bronchodilators: reduction of airway resistance
  - antibiotics: treatment of infections
  - reverse medications that may be contributing (e.g. narcotics)
- maintain oxygenation (see above)
- diet: increased carbohydrates can increase $PaCO_2$ in those with mechanical or limited alveolar ventilation; high lipids decrease $PaCO_2$

Dead Space
- Ventilation without perfusion
- The opposite of shunt

Causes of Hypercapnia
- Low total ventilation
- High dead space ventilation
- High CO_2 production
- High inspired CO_2

In chronic hypercapnia, supplemental O_2 may worsen hypoxemia by worsening V/Q mismatch, Haldane effect, and/or decreasing respiratory drive (in order of physiologic importance); but do not deny oxygen if the patient is hypoxic

In COPD patients with chronic hypercapnia ("CO_2 retainers"), provide supplemental oxygen to achieve target SaO_2 from 88-92%

Acute Respiratory Distress Syndrome

Definition

- clinical syndrome characterized by severe respiratory distress, hypoxemia, and noncardiogenic pulmonary edema
- The Berlin Criteria for ARDS
  - acute onset
    - within 7 d of a known clinical insult or of patient noticing new or worsening of respiratory symptoms
      - usually occurs within 72 h of presumed trigger
    - bilateral opacities consistent with pulmonary edema on either CT or CXR
    - not fully explained by cardiac failure/fluid overload, but patient may have concurrent heart failure
    - objective assessment of cardiac function (e.g. echocardiogram) should be performed if no clear risk factors

Acute Lung Injury
ALI is an outdated term that has the same definition as ARDS but with a PaO_2/FiO_2 ≤300. The Berlin Definition removed ALI and replaced it with the term mild ARDS

Etiology
- direct lung injury
  - airway: aspiration (gastric contents, drowning), pneumonia, inhalation injury (oxygen toxicity, nitrogen dioxide, smoke)
  - circulation: embolism (fat, amniotic fluid), reperfusion injury
- indirect lung injury
  - circulation: sepsis, shock, trauma, blood transfusion, pancreatitis
  - neurogenic: head trauma, intracranial hemorrhage, drug overdose (narcotics, sedatives, tricyclic antidepressants)

Pathophysiology
- disruption of alveolar capillary membranes ➔ leaky capillaries ➔ interstitial and alveolar pulmonary edema ➔ reduced compliance, V/Q mismatch, shunt, hypoxemia, pulmonary HTN

Clinical Course
A. Exudative Phase
- first 7 d of illness after exposure to ARDS precipitant
- alveolar capillary endothelial cells and type I pneumocytes are injured, resulting in loss of normally tight alveolar barrier
- patients develop dyspnea, tachypnea, increased work of breathing
  - these result in respiratory fatigue and eventually respiratory failure (see *Hypoxemic Respiratory Failure*, R26)

B. Fibroproliferative Phase
- after day 7
- may still experience dyspnea, tachypnea, fatigue, and hypoxemia
- most patients clinically improve and are able to wean off mechanical ventilation
- some patients develop fibrotic lung changes that may require long-term support on supplemental oxygen or even mechanical ventilation
- if fibrosis present, associated with increased mortality

Treatment
- based on ARDS Network (see *Landmark Respirology Trials*, R36)
- treat underlying disorder (e.g. antibiotics if infection present)
- mechanical ventilation using low tidal volumes (<6 mL/kg) to prevent barotrauma
  - use optimal amount of PEEP to keep airways open and allow the use of lower FiO_2
  - may consider using prone ventilation, ± inhaled nitric oxide, short term paralytics (<48 h) or ECMO (extracorporeal membrane oxygenation) if conventional treatment is failing
- fluids and inotropic therapy (e.g. dopamine, dobutamine) if cardiac output inadequate
- pulmonary-arterial catheter now seldom used for monitoring hemodynamics
- mortality: 30-40%, usually due to non-pulmonary complications
- sequelae of ARDS include residual pulmonary impairment, severe debilitation, polyneuropathy and psychological difficulties, which gradually improve over time
- most survivors eventually regain near-normal lung function, often with mildly reduced diffusion capacity

Categorization of ARDS as Mild, Moderate or Severe – The Berlin Criteria

ARDS Severity	PaO_2/FiO_2 (mmHg)*	Mortality (95% CI)
Mild	200-300	27 (24-30)%
Moderate	100-200	32 (29-34)%
Severe	<100	45 (42-48)%

*on ≥5 cm H20 PEEP, #P<0.001
JAMA 2012;307:2526-2533

Risk Factors for Aspiration Pneumonia

Categories	Examples
Decreased level of consciousness	Alcoholism
Upper GI tract disorders	Dysphagia, esophageal disorders
Mechanical instrumentation	Intubation, nasogastric tube, feeding tube
Neurologic conditions	Dementia, Parkinson's disease
Others	Protracted vomiting

Neoplasms

Lung Cancer

- see General and Thoracic Surgery, GS20

Approach to the Solitary Pulmonary Nodule

- see Medical Imaging, *Lung Abnormalities*, MI7
- see General and Thoracic Surgery, GS22

Sleep-Related Breathing Disorders

Hypoventilation Syndromes

Definition
- group of syndromes characterized by hypoventilation during sleep, though daytime hypercapnia may also be a feature
- superimposed sleep apnea may be present
- categories of hypoventilation syndromes include: medical disorders, lung parenchymal or airway disease (typically severe), chest wall disorder (deformity such as kyphoscoliosis), neurologic disorder (brainstem lesions), respiratory muscle weakness (neuromuscular disease, myopathy), medications (opiates and other sedatives), obesity-hypoventilation syndrome (Pickwickian syndrome) (BMI >30 kg/m^2 and no other cause of hypoventilation identified), congenital central alveolar hypoventilation syndrome, idiopathic hypoventilation syndrome

Treatment
- management of the underlying condition
- usually PAP therapy (frequently BiPAP, which delivers ventilation in addition to airway splinting)

Normal Respiratory Changes during Sleep
- Tidal volume decreases, leading to decreased minute ventilation
- $PaCO_2$ increases (due to decreased minute ventilation)
- Pharyngeal dilator muscles relax causing increased upper airway resistance

Sleep Apnea

Definition
- episodic decreases in airflow during sleep
- quantitatively measured by the Apnea-Hypopnea Index (AHI) = # of apneas and hypopneas per hour of sleep
- sleep apnea generally accepted to be present if AHI ≥5 events/h
  - AHI: Mild OSA 5-15 events/h, Moderate 15-30 events/h, Severe >30 events/h

Classification
- obstructive sleep apnea
  - caused by transient, episodic obstruction of the upper airway
  - absent or reduced airflow despite persistent respiratory effort
- central sleep apnea (see Neurology, N49)
  - hypercapnic CSA caused by transient, episodic decreases in CNS drive to breathe, typically seen in patients with sleep hypoventilation syndromes (see *Hypoventilation Syndromes*)
  - hypocapnic CSA, most commonly Cheyne-Stokes breathing, typically seen in patients with congestive heart failure and sometimes stroke; characterized by a crescendo-decrescendo pattern of alternating apnea and hyperpnea
- mixed sleep apnea
  - features of both CSA and OSA
  - loss of hypoxic and hypercapnic drives to breathe secondary to "resuscitative breathing": overcompensatory hyperventilation upon awakening from hypoxia caused by OSA

- **Apnea**: reduction in airflow ≥90% from baseline, lasting for ≥10 s
- **Hypopnea**: reduction in airflow ≥30% from baseline, lasting for ≥10 s, associated with oxygen desaturation ≥3% or EEG arousal
- **Hyperpnea**: period of increased ventilation, typically in the context of resumption in breathing, following an apnea or hypopnea
- **Obstructive apnea**: absent airflow despite respiratory effort, due to upper airway occlusion
- **Central apnea**: absent airflow, due to absent or reduced respiratory effort
- **Mixed apnea**: absent airflow, with features of both central and obstructive events

SLEEP TESTING

Polysomnography
- sleep study, usually in-laboratory with technologist in attendance
- evaluates sleep stages and arousals (using EEG, EOG, EMG), airflow, ribcage and abdominal movement, ECG, SaO_2, limb movements, snoring, body position, and video recording
- indications:
  - evaluation for suspected sleep disordered breathing in a patient with compatible symptoms or risk factors
  - evaluation for non-respiratory causes of excessive daytime sleepiness
  - evaluation of selected cases of insomnia and abnormal behaviours during sleep
  - titration of PAP therapy, to determine optimal settings
  - assessment of objective response to other interventions (e.g. oral appliances for sleep apnea, positional therapy)

Home Sleep Apnea Testing
- done in the home, unattended
- evaluates a limited number of parameters primarily focused on the diagnosis of OSA; EEG monitoring typically not included
- indication: evaluation for suspected OSA, in patients without significant cardiopulmonary comorbidities

Treatment of Adult Obstructive Sleep Apnea with Positive Airway Pressure: An American Academy of Sleep Medicine Systematic Review, Meta-Analysis, and GRADE Assessment
J Clin Sleep Med 2019;15:301-334
Purpose: To provide supporting evidence for the clinical practice guidelines for the treatment of OSA in adults using PAP.
Methods: Systematic review including 184 studies comparing use of PAP with no treatment and studies comparing different PAP modalities.
Conclusions: The data demonstrated that PAP compared to no treatment results in a clinically significant reduction in disease severity, sleepiness, blood pressure, motor vehicle accidents, and improvement in sleep-related quality of life in adults with OSA.

OSA

Risk Factors
- obesity, craniofacial abnormalities, crowded oropharynx (including enlarged tonsils, large tongue), short/wide neck (neck circumference ≥17 inches (≥43 cm) for men and ≥16 inches (≥40.6 cm) for women), nasal obstruction
- more common in males than females (pre-menopause)

Signs and Symptoms
- airway obstruction: snoring, apneas, choking and gasping spells (may be witnessed by a bed partner)
- sleep fragmentation: nocturnal awakenings, nocturia, unrefreshing sleep, daytime somnolence, irritability, depression, memory loss
- other sequelae: morning headaches, findings of complications from OSA

Complications
- increased risk of: hypertension, cardiovascular disease (e.g. CAD, CHF, arrhythmia), stroke, motor vehicle collisions, polycythemia, pulmonary hypertension, type 2 DM

Treatment
- modifiable factors: weight loss, decreased alcohol/sedatives, treatment of nasal congestion (usually modest effect), avoidance of supine sleep
- CPAP very effective but can be limited by compliance
- oral appliances typically less effective at reducing AHI but better tolerated by some patients
- surgical intervention can be helpful in selected patients (e.g. tonsillectomy, tongue base and jaw procedures, tracheostomy)

CSA

Risk Factors
- hypercapnic CSA: underlying disorder causing sleep hypoventilation syndrome (see Hypov*entilation Syndromes,* R29)
- non-hypercapnic CSA (mostly Cheyne-Stokes breathing): congestive heart failure, atrial fibrillation, high altitude

Signs and Symptoms
- typically those of underlying medical condition
- those with hypercapnia typically have daytime somnolence; seen less frequently in non-hypercapnic CSA

Complications
- hypercapnic CSA: may have complications of chronic hypoxemia including cor pulmonale
- hypocapnic CSA: higher mortality but not clear whether this is due to Cheyne-Stokes breathing, or if Cheyne-Stokes breathing is a marker of severe heart disease

Treatment
- both hypercapnic and non-hypercapnic CSA: treatment of underlying medical conditions, especially optimization of congestive heart failure in Cheyne-Stokes breathing
- hypercapnic CSA: typically benefit from BiPAP
- hypocapnic CSA: has not been shown to benefit from CPAP or BiPAP; clinical trials of adaptive servo-ventilation (ASV) are ongoing, but one study showed a signal for harm

Introduction to Intensive Care

Intensive Care Unit Basics

- goal is to stabilize critically ill patients: hemodynamic, respiratory, cardiac instability, or need for close monitoring

Lines and Catheters

- arterial lines
  - monitor beat-to-beat blood pressure variations, obtain blood for routine ABGs
  - common sites: radial and femoral arteries
- central venous catheter (central line)
  - administer IV fluids, monitor CVP, insert pulmonary artery catheters
  - administer total parenteral nutrition and agents too irritating for peripheral line (e.g. vasopressors, chemotherapy)
  - common sites: internal jugular vein, subclavian vein, femoral vein

- pulmonary arterial catheter
  - balloon guides the catheter from a major vein to the right heart
  - measures PCWP via a catheter wedged in distal pulmonary artery
  - PCWP reflects the LA and LV diastolic pressure (barring pulmonary venous or mitral valve disease)
  - indications (now used infrequently due to associated complications)
    - diagnosis of shock, primary pulmonary HTN, valvular disease, intracardiac shunts, cardiac tamponade, PE
    - assessment of hemodynamic response to therapies
    - differentiation of high- vs. low-pressure pulmonary edema
    - management of complicated MI, multiorgan system failure and/or severe burns, or hemodynamic instability after cardiac surgery
  - absolute contraindications
    - tricuspid or pulmonary valve mechanical prosthesis
    - right heart mass (i.e. thrombus or tumour)
    - tricuspid or pulmonary valve endocarditis

Table 28. Useful Equations and Cardiopulmonary Parameters

Equations and Cardiopulmonary Parameters	
BSA = [Ht (cm) + Wt (kg) – 60]/100	PCWP = LVEDP
SV = CO / HR	SVI = CI / HR
CI = CO / BSA	RV Ejection Fraction = SV / RVEDV
SVRI = [(MAP – RAP) 80]/CI	PP = sBP – dBP
P:F ratio = PaO_2 / FiO_2	MAP = 1/3 sBP + 2/3 dBP = dBP + 1/3 PP

BSA = body surface area; CI = cardiac index; CO = cardiac output; dBP = diastolic blood pressure; HR = heart rate; LVEDP = left ventricular end diastolic pressure;
MAP = mean arterial pressure; PCWP = pulmonary capillary wedge pressure; PP = pulse pressure; RAP = right atrial pressure; RVEDV = right ventricular end diastolic volume; sBP = systolic blood pressure; SV = stroke volume; SVI = stroke volume index; SVRI = systemic vascular resistance index

Intensive vs. Conventional Glucose Control in Critically Ill Patients
NEJM 2009;360:1283-1297
Purpose: To assess whether intensive glucose control improves mortality in critically ill patients.
Study: Prospective, randomized controlled trial.
Population: 6104 patients expected to require ICU treatment for 3 or more consecutive days.
Intervention: Patients were randomized to insulin therapy regimens with intensive (blood glucose 4.5-6 mM) or conventional (blood glucose 10 mM or less) glucose control targets. Intravenous insulin therapy was used to maintain blood glucose in target range. Primary Outcome: Death from any cause within 90 d after randomization.
Results: The odds ratio for death in the intensive control group was 1.14 (95% CI 1.02-1.28; P=0.02) and this effect did not differ between surgical and medical patients. Severe hypoglycemia (blood glucose <2.2 mM) was significantly more common in the intensive management group (6.8% vs. 0.5%; P<0.001).
Conclusion: Intensive insulin therapy in ICU patients increased mortality compared to blood glucose targeting of <10 mM with a number needed to harm of 38.

Organ Failure

Table 29. Types of Organ Failure

Type of Failure	Clinical Features	Treatment
Respiratory Failure (see *Respiratory Failure*, R26)	Hypoxemia Hypercapnia	Treat underlying cause (e.g. lung disease, shunt, V/Q mismatch, drug-related, cardiac) Manage mechanical ventilation settings Supplemental oxygen
Cardiac Failure (see Cardiology and Cardiac Surgery, C40)	Hypotension Decreased urine output Altered mental status Arrhythmia Hypoxia	Treat underlying cause (e.g. myocardial ischemia, LV failure, bradycardia, tachycardia, blood loss, adrenal insufficiency) Correct volume status Vasopressors Inotropes Intra-aortic balloon pump
Coagulopathy (see Hematology, H34 and H57)	Increased INR or PTT Low platelet count Bleeding, bruising	Treat underlying cause (e.g. thrombocytopenia, drug-related, immune-related, DIC) Transfusion of blood products, clotting factors
Liver Failure (see Gastroenterology, G40)	Elevated transaminases, bilirubin Coagulopathy Jaundice Altered mental status (encephalopathy) Hypoglycemia	Treat underlying cause (e.g. viral hepatitis, drug related, metabolic) Lactulose Liver transplant
Renal Injury (see Nephrology, NP20)	Elevated creatinine Reduced urine output Signs of volume overload (e.g. CHF, effusions)	Treat underlying cause (e.g. shock, drug-related, obstruction) Correct volume and electrolyte status, eliminate toxins Diuretics Dialysis

Causes of SHOCK

Spinal (neurogenic), Septic
Hemorrhagic
Obstructive (e.g. tension pneumothorax, cardiac tamponade, PE)
Cardiogenic (e.g. arrhythmia, MI)
Anaphyla**K**tic

Shock

Definition

- see Emergency Medicine, ER3
- inadequate tissue perfusion potentially resulting in end organ injury
  - categories of shock
    - hypovolemic: hemorrhage, dehydration, vomiting, diarrhea, interstitial fluid redistribution
    - cardiogenic: myopathic (myocardial ischemia ± infarction), mechanical, arrhythmic, pharmacologic

- **Shock**: Clinical Correlation
- **Hypovolemic:** patients have cool extremities due to peripheral vasoconstriction
- **Cardiogenic**: patients usually have signs of left-sided heart failure
- **Obstructive**: varied presentation
- **Distributive**: patients have warm extremities due to peripheral vasodilation

- obstructive: massive PE (saddle embolus), pericardial tamponade, constrictive pericarditis, increased intrathoracic pressure (e.g. tension pneumothorax)
- distributive: sepsis, anaphylaxis, neurogenic, endocrine, toxins

Table 30. Changes Seen in Different Classes of Shock

	Hypovolemic	Cardiogenic	Obstructive	Distributive
HR	↑	↑, N, or ↓	↑	↑ or ↓
BP	↓	↓	↓	↓
JVP	↓	↑	↑	↓
Extremities	Cold	Cold	N or Cold	Warm
Other	Look for visible hemorrhage or signs of dehydration	Bilateral crackles on chest exam	Depending on cause, may see pulsus paradoxus, Kussmaul's sign, or tracheal deviation	Look for obvious signs of infection or anaphylaxis

Treatment
- treat underlying cause (hypovolemia is the most common cause)
- treatment goal is to return critical organ perfusion to normal (e.g. normalize BP)
- common treatment modalities include:
  - fluid resuscitation (NOT in cardiogenic shock)
  - inotropes (e.g. dobutamine), vasopressors (e.g. norepinephrine), vasopressin
  - revascularization or thrombolytics for ischemic events
  - needle decompression or tube thoracostomy for suspected tension pneumothorax

Sepsis

- the leading cause of death in noncoronary ICU settings is multi-organ failure due to sepsis
- the predominant theory is that sepsis is attributable to uncontrollable immune system activation

Definitions
- sepsis: life threatening organ dysfunction caused by dysregulated host response to infection (Table 31, R33)
- septic shock: a subset of sepsis, where sufficient circulatory and/or cellular/metabolic abnormalities substantially increase mortality. Clinically defined as sepsis with persisting hypotension requiring vasopressors to maintain MAP ≥65 mmHg and having a serum lactate ≥2 mmol/L (18 mg/dL) despite adequate fluid resuscitation

Signs and Symptoms
- new guidelines recommend the use of quick SOFA (qSOFA) criteria and SOFA score to replace SIRS criteria
- in patients with suspected infection, bedside application of qSOFA criteria identifies individuals with high likelihood of poor outcomes, including prolonged ICU stay and/or death
- a positive qSOFA (≥2 criteria) should prompt application of the SOFA score, and further evaluation of possible infection and organ dysfunction
- in the context of suspected infection, a SOFA score ≥2 reflects an overall mortality risk of 10%
- the absence of ≥2 criteria on either qSOFA or SOFA score should not delay or defer investigation or treatment of infection or any other aspect of care deemed necessary by the practitioners

Systemic Inflammatory Response Syndrome (SIRS): generalized inflammatory reaction caused by infectious and noninfectious entities, manifested by two or more of:
- Body temperature >38°C or <36°C
- Heart rate >90/min
- Respiratory rate >20/min or $PaCO_2$ <32 mmHg
- WBC >12000 cells/mL or <4000 cells/mL or >10% bands

Quick SOFA (qSOFA) Criteria
- Respiratory rate ≥22/min
- Altered mentation
- Systolic blood pressure ≤100 mmHg

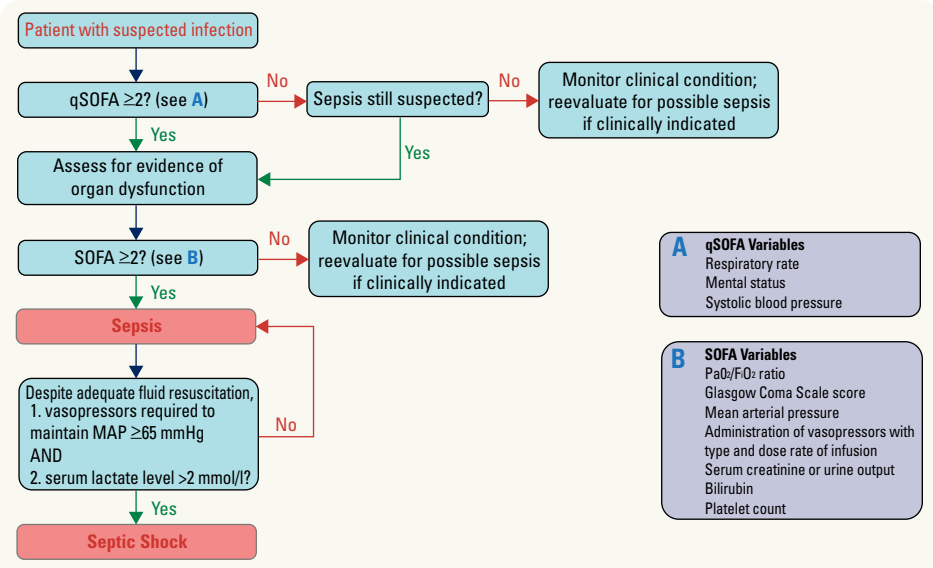
Goal-Directed Resuscitation for Patients with Early Septic Shock
NEJM 2014: 371;1496-1406
Study: Prospective, randomized controlled trial.
Population: 1600 patients in Australia and New Zealand presenting to the emergency department with early septic shock.
Intervention: Patients were randomized to receive early goal directed therapy (EGDT) or usual care.
Outcome: The primary outcome was all-cause mortality within 90 d of randomization.
Results: The rate of death did not significantly differ between patients treated with EGDT or usual care (absolute risk difference EGDT vs. usual care = -0.3%, 95% CI -4.1 to 3.6%; P=0.90). EGDT treated patients received more intravenous fluids, vasopressor infusions, red blood cell transfusions, and dobutamine (P<0.0001 for all). Survival time, in-hospital mortality, duration of organ support, and length of hospital stay did not significantly differ between patients randomized to EGDT or usual care.
Conclusions: EGDT did not improve all-cause mortality at 90 d in patients presenting to the emergency department with early septic shock.

Corticosteroids in Sepsis: An Updated Systematic Review and Meta-Analysis
Crit Care Med 2018;46:1411-1420
Purpose: Address the efficacy and safety of corticosteroids in critically ill patients with sepsis.
Methods: MEDLINE, EMBASE, CENTRAL, and LILACS were searched for RCTs comparing any corticosteroid to placebo or no corticosteroid in critically ill children and adults with sepsis.
Results: 42 RCTs including 10194 patients. Corticosteroids may achieve a small reduction or no reduction in the relative risk of dying in the short-term (relative risk, 0.93; 95% CI 0.84-1.03; 1.8% absolute risk reduction; 95% CI 4.1% reduction to 0.8% increase), and possibly achieve a small effect on long-term mortality based on moderate certainty (relative risk, 0.94; 95% CI 0.89-1.00; 2.2% absolute risk reduction; 95% CI 4.1% reduction to no effect).
Conclusions: In critically ill patients with sepsis, corticosteroids possibly result in a small reduction in mortality while possibly increasing the risk of neuromuscular weakness.

Table 31. Sequential (Sepsis-Related) Organ Failure Assessment (SOFA) Score

	Score				
System	**0**	**1**	**2**	**3**	**4**
Respiratory					
PaO_2/FiO_2, mmHg (kPa)	≥400 (53.3)	<400 (53.3)	<300 (40)	<200 (26.7) with respiratory support	<100 (13.3) with respiratory support
Coagulation					
Platelets, $x10^3/\mu L$	≥150	<150	<100	<50	<20
Liver					
Bilirubin, µmol/L (mg/dL)	<20 (1.2)	20-32 (1.2-1.9)	33-101 (2.0-5.9)	102-204 (6.0-11.9)	>204 (12.0)
Cardiovascular	MAP ≥70 mmHg	MAP <70 mmHg	Dopamine <5a or dobutamine (any dose)a	Dopamine 5.1-15a or epinephrine <0.1a or norepinephrine <0.1a	Dopamine >15a or epinephrine >0.1a or norepinephrine >0.1a
Central Nervous System					
Glasgow coma scale score	15	13-14	10-12	6-9	<6
Renal					
Creatinine, µmol/L (mg/dL)	<110 (1.2)	110-170 (1.2-1.9)	171-299 (2.0-3.4)	300-440 (3.5-4.9)	>440 (5.0)
Urine output, mL/d				<500	<200

[a]Catecholamine doses are given as µg/kg/min for at least 1hr
Table adapted from Singer et al. The Third International Consensus Definitions for Sepsis and Septic Shock (Sepsis-3). JAMA 2016;315(8):801-810



The baseline Sequential (sepsis-related) Organ Failure Assessment (SOFA) score should be assumed to be zero unless the patient is known to have pre-existing (acute or chronic) organ dysfunction before the onset of infection. qSOFA indicated quick SOFA; MAP, mean arterial pressure.

Figure 11. Approach to sepsis
Figure adapted from Singer et al. The Third International Consensus Definitions for Sepsis and Septic Shock (Sepsis-3). JAMA 2016;315(8):801-810

Treatment

- identify the cause and source of infection: blood, sputum, urine Gram stain, and C&S
- initiate empiric antibiotic therapy
- monitor, restore, and maintain hemodynamic function

Surviving Sepsis

Adapted from International Guidelines for Management of Severe Sepsis and Septic Shock 2012

- adjustments of cardiac preload, afterload, and contractility to balance oxygen delivery with demand
- initial resuscitation (goals during first 6 h of resuscitation for sepsis induced hypotension persisting after initial fluid challenge or blood lactate ≥4 mmol/L)
- maintain CVP 8-12 mmHg with IV crystalloids/colloids
  - maintain MAP ≥65 mmHg with use of vasopressor agents, first line: norepinephrine
  - urine output ≥0.5 mL/kg/hr
  - central venous (SVC) or mixed oxygen saturation 70% or 65%, respectively
  - in patients with elevated lactate levels target resuscitation to normalize lactate
  - corticosteroid replacement therapy not indicated if adequate hemodynamic stability achieved with fluid resuscitation and vasopressor therapy

- infection control
  - prompt diagnosis of infection
    - cultures as clinically indicated prior to antibiotic therapy if no significant delay
    - imaging studies performed promptly to confirm possible infectious source
  - antibiotic therapy
- administer effective IV antimicrobials within first hour of recognition of sepsis
  - choice of anti-infective therapy should consider activity against all likely pathogens and penetrance of adequate concentration into tissue presumed to be source of infection
  - antimicrobial regimen should be reassessed daily for potential de-escalation
- surgical source control when appropriate
- supportive oxygenation and ventilation using lung-protective regimen
- early nutritional support: enteral route is used to preserve function of intestinal mucosal barrier
- DVT/PE prophylaxis
- advanced care planning, including the communication of likely outcome and realistic goals of treatment with patients and families

Common Medications

Table 32. Common Medications for Respiratory Diseases

	Drug	Typical Adult Dose	Indications	Side Effects
β2-AGONISTS				
Short-Acting β2-Agonists	salbutamol/albuterol (Ventolin®, Airomir®) (light blue/navy MDI or diskus) terbutaline (Bricanyl®) (blue turbuhaler)	1-2 puffs q4-6 h PRN	Bronchodilator in acute reversible airway obstruction	CV (angina, flushing, palpitations, tachycardia, can precipitate atrial fibrillation), CNS (dizziness, H/A, insomnia, anxiety), GI (diarrhea, N/V), rash, hypokalemia, paroxysmal bronchospasm
Long-Acting β2-Agonists	salmeterol (Serevent®) (green diskus), formoterol (Oxeze®, Foradil®) (blue/green turbuhaler or aerolizer), indacaterol (Onbrez®) (blue/white breezhaler)	1-2 puffs BID 1 puff daily	Maintenance treatment (prevention of bronchospasm) in COPD, asthma	
Combination Long-Acting β2-Agonist and Inhaled Corticosteroid	fluticasone and salmeterol (Advair®) (purple MDI or diskus), budesonide and formoterol (Symbicort®) (red turbuhaler), mometasone and formoterol (Zenhale®) (blue MDI), fluticasone furoate and Vilanterol (Breo Ellipta®) (light gray and blue inhaler)	1 puff BID 2 puffs BID 1 puff daily	COPD and asthma	Common: CNS, H/A, dizziness Resp: URTI, GI (N/V, diarrhea, pain/discomfort, oral candidiasis)
Combination Short-Acting β2-Agonist and Short-Acting Anti-Cholinergic	ipratropium/salbutamol (Combivent®, Respimat®) (orange respimat)	1 puff QID	Bronchodilator used in COPD	Palpitations, anxiety, dizziness, fatigue, H/A, N/V, dry mucous membranes, urinary retention, increased toxicity in combination with other anticholinergic drugs
Combination Long-Acting β2-Agonist and Long-Acting Anti-Cholinergic	umeclidinium/vilanterol (Anoro®) (red ellipta) aclidinium/formoterol (Duaklir®) (yellow genuair) tiotropium/olodaterol (Inspiolto®) (green respimat) indacaterol/glycopyrronium (Ultibro®) (yellow breezhaler)	1 puff daily 1 puff BID 1 puff daily 1 puff daily	Bronchodilator used in COPD	Palpitations, anxiety, dizziness, fatigue, H/A, N/V, dry mucous membranes, urinary retention, increased toxicity in combination with other anticholinergic drugs
ANTICHOLINERGICS				
Short-Acting Anti-Cholinergic	ipratropium bromide (Atrovent®) (clear/green MDI)	2-3 puffs QID	Bronchodilator used in asthma and COPD	Palpitations, anxiety, dizziness, fatigue, H/A, N/V, dry mucous membranes, urinary retention, increased toxicity in combination with other anticholinergic drugs
Long-Acting Anti-Cholinergic	tiotropium bromide (Spiriva®) (green handihaler or respimat), glycopyrronium bromide (Seebri®) (orange breezhaler), umeclidinium (Incruse™) (green ellipta), aclidinium (Genuair®, Tudorza®) (green inhaler)	1 puff QAM 1 puff daily	Bronchodilator used in asthma and COPD	Palpitations, anxiety, dizziness, fatigue, H/A, N/V, dry mucous membranes, urinary retention, increased toxicity in combination with other anticholinergic drugs
CORTICOSTEROIDS				
Inhaled	fluticasone (Flovent®) (orange/peach MDI or diskus) budesonide (Pulmicort®) (brown turbuhaler) ciclesonide (Alvesco®) (red MDI) beclomethasone (QVAR®, Vanceril®) (brown MDI) mometasone (Asmanex®) (pink/grey/brown twisthaler) fluticasone furoate (Arnuity®) (orange ellipta) futicasone propionate (Aermony RespiClick®) (light green inhaler)	2-4 puffs BID 2 puffs BID 1 puff daily or BID 1-4 puffs BID 1 puff daily or BID 1 puff daily 1 puff BID	Maintenance treatment of asthma	H/A, fever, N/V, MSK pain, URTI, throat irritation, growth velocity reduction in children/adolescents, HPA axis suppression, increased pneumonia risk in COPD
Systemic	prednisone (Apo-prednisone®, Deltasone®) methylprednisolone (Depo-Medrol®, Solu-Medrol®)	Typically 40-60 mg/d PO 125 mg q8 h IV (sodium succinate) loading dose 2 mg/kg then 0.5-1 mg/kg q6 h for 5 d	Acute exacerbation of COPD; severe, persistent asthma, *Pneumocystis carinii* pneumonia Status asthmaticus	Endocrine (hirsutism, DM/glucose intolerance, Cushing's syndrome, HPA axis suppression), GI (increased appetite, indigestion), ocular (cataracts, glaucoma), edema, avascular necrosis, osteoporosis, H/A, psychiatric (anxiety, insomnia), easy bruising

See Infectious Diseases, ID26 for the management of pulmonary tuberculosis

Table 32. Common Medications for Respiratory Diseases

	Drug	Typical Adult Dose	Indications	Side Effects
ADJUNCT AGENTS				
	theophylline (Uniphyll®)	400-600 mg once daily	Treatment of symptoms of reversible airway obstruction due to COPD	GI upset, diarrhea, N/V, anxiety, H/A, insomnia, muscle cramp, tremor, tachycardia, premature ventricular contractions, arrhythmias Toxicity: persistent, repetitive vomiting, seizures
LEUKOTRIENE ANTAGONISTS				
	omalizumab (Xolair®)	150-375 mg SC q2-4 wk	Moderate-severe persistent asthma	H/A, sinusitis, pharyngitis, URTI, viral infection, thrombocytopenia, anaphylaxis
PDE-4 INHIBITORS				
	roflumilast (Daxas®)	500 µg PO once daily	Severe emphysema, with frequent exacerbations	Weight loss, suicidal ideation
ANTIBIOTICS – COMMUNITY ACQUIRED PNEUMONIA				
Macrolide	erythromycin	250-500 mg PO TID x 7-10 d 500 mg PO x 1 dose, then	Alternate to doxycycline or fluoroquinolone	GI (abdominal pain, diarrhea, N/V), H/A, prolonged QT, ventricular arrhythmias, hepatic impairment
	azithromycin	250 mg once daily x 4		GI (diarrhea, N/V, abdominal pain), renal failure, deafness
	clarithromycin	1000 mg once daily or 500 mg PO BID x 7-10 d		H/A, rash, GI (diarrhea, N/V, abnormal taste, heartburn, abdominal pain), increased urea
Doxycycline		100 mg PO BID x 7-10 d	Alternate to macrolide or fluoroquinolone	Photosensitivity, rash, urticaria, anaphylaxis, diarrhea, enterocolitis, tooth discolouration in children
Fluoroquinolone	levofloxacin (Levaquin®)	500 mg PO once daily x 7-10 d	Alternate to macrolide or doxycycline	CNS (dizziness, fever, H/A), GI (N/V, diarrhea, constipation), prolonged QT
	moxifloxacin (Avelox®)	400 mg PO once daily x 7 d		
ANTIBIOTICS – HOSPITAL ACQUIRED PNEUMONIA				
3rd gen Cephalosporin	ceftriaxone (Rocephin®)	1-2 g IV once daily x 7-10 d	Combine with fluoroquinolone or macrolide	Rash, diarrhea, eosinophilia, thrombocytosis, leukopenia, elevated transaminases
Fluoroquinolone	levofloxacin	750 mg PO once daily x 5 d	Combine with 3rd gen cephalosporin	Rash, diarrhea, eosinophilia, thrombocytosis, leukopenia, elevated transaminases
	moxifloxacin	400 mg PO once daily x 7 d (5 d for AECOPD)		
Piperacillin/Tazobactam (Tazocin®)		4.5 g IV q6-8 h x 7-10 d	Suspect *Pseudomonas*	CNS (confusion, convulsions, drowsiness), rash, hematologic (abnormal platelet aggregation, prolonged PT, positive Coombs)
Vancomycin (Vancocin®)		1 g IV BID x 7-10 d	Suspect MRSA	CNS (chills, drug fever), hematologic (eosinophilia), rash, red man syndrome, interstitial nephritis, renal failure, ototoxicity
Macrolide	azithromycin	500 mg IV once daily x 2 d, then 500 mg PO once daily x 5 d	Suspect *Legionella*	CNS (chills, drug fever), hematologic (eosinophilia), rash, red man syndrome, interstitial nephritis, renal failure, ototoxicity
	clarithromycin	1000 mg once daily or 500 mg PO BID x 7-10 d		
ICU MEDICATIONS				
Pressors/Inotropes	norepinephrine (Levophed®)	0.5-30 µg/min IV	Acute hypotension	Angina, bradycardia, dyspnea, hyper/hypotension, arrhythmias
	phenylephrine	0.5 µg/kg/min IV	Severe hypotension	
	dobutamine	2-20 µg/kg/min IV	Inotropic support	See above
Sedatives/Analgesia	fentanyl (opioid class)	50-100 µg then 50-unlimited µg/h IV	Sedation and/or analgesia	Bradycardia, respiratory depression, drowsiness, hypotension
	propofol (anesthetic)	1-3 mg/kg then 0.3-5 mg/kg/h IV	Sedation and/or analgesia	Apnea, bradycardia, hypotension (good for ventilator sedation)

See Infectious Diseases, ID26 for the management of pulmonary tuberculosis

Landmark Respirology Trials

Trial Name	Reference	Clinical Trial Details
ACUTE RESPIRATORY DISTRESS SYNDROME		
OSCILLATE	NEJM 2013;368:795-805	**Title:** High-Frequency Oscillation in Early Acute Respiratory Distress Syndrome **Purpose**: Assess the reduction in mortality conferred by high-frequency oscillatory ventilation (HFOV) among adults with ARDS. **Methods**: Adults with new-onset moderate-severe ARDS were randomized to HFOV or a control ventilation strategy. The primary outcome was all-cause in-hospital mortality. **Results**: In-hospital mortality was 47% in the HFOV group and 35% in the control group (RR 1.33; 95% CI 1.09 to 1.64; P=0.005). Patients in the HFOV group received higher doses of midazolam (P<0.01) and vasoactive drugs (91% vs. 84%; P=0.01) than control patients. **Conclusions**: Early HFOV in patients with moderate-to-severe ARDS may increase in-hospital mortality.
PROSEVA	NEJM 2013;368:2159-68	**Title:** Prone Positioning in Severe Acute Respiratory Distress Syndrome **Purpose**: Evaluate the effect of early application of prone positioning on patients with severe ARDS. **Methods**: 466 patients with severe ARDS were randomized to undergo prone-positioning sessions >16 hr or remain supine. The primary outcome was the proportion of patients who died from any cause at 28 d. **Results**: The 28 d mortality was 16.0% in the prone group and 32.8% in the supine group (hazard ratio 0.39; 95% CI 0.25 to 0.63; P<0.001). Unadjusted 90 d mortality was 23.6% in the prone group and 41.0% in the supine group (hazard ratio 0.44; 95% CI 0.29 to 0.67; P<0.001). The incidence of complications did not differ significantly between groups. **Conclusions**: Early application of prolonged prone-positioning sessions in patients with severe ARDS decreased 28 d and 90 d mortality.
ACURASYS	NEJM 2010;363:1107-16	**Title:** Neuromuscular Blockers in Early Acute Respiratory Distress Syndrome **Purpose**: Evaluate clinical outcomes after 2 d of therapy with neuromuscular blocking agents, in patients with ARDS. **Methods**: 340 patients presenting to the ICU with severe ARDS were randomized to cisatracurium besylate or placebo. The primary outcome was the proportion of patients who died before hospital discharge. **Results**: The hazard ratio for 90 d mortality was 0.68 (95% CI 0.48 to 0.98; P=0.04). The crude 90 d mortality was 31.6% in the intervention group and 40.7% in the placebo group. The rates of ICU-acquired paresis did not differ between groups. **Conclusions**: Early administration of a neuromuscular blocking agent in patients with severe ARDS improved 90-d survival and reduced time on a ventilator.
ARDS Network	NEJM 2000;342:1301-08	**Title:** Ventilation with Lower Tidal Volumes as Compared with Traditional Tidal Volumes for Acute Lung Injury and the Acute Respiratory Distress Syndrome **Purpose**: Determine whether ventilation with lower tidal volumes would improve clinical outcomes in ARDS patients. **Methods**: Patients with ALI and ARDS were randomized to traditional ventilation treatment (12 mL/kg) or a lower tidal-volume ventilation strategy (6 mL/kg). The primary outcome was death before patient discharge. **Results**: Mortality was lower in patients treated with lower tidal volumes (31.0% vs. 39.8%; P=0.007), and the number of days without ventilation use was greater in this group (P=0.007). **Conclusions**: Both all-cause mortality and days with ventilator use were decreased in ARDS patients ventilated with a low tidal volume strategy.
ASTHMA		
EXTRA	Ann Intern Med 2011;154:573-82	**Title:** Omalizumab in Severe Allergic Asthma Inadequately Controlled with Standard Therapy **Purpose**: Evaluate the safety and efficacy of omalizumab in inadequately controlled severe asthma, without additional inhaler therapy. **Methods**: 850 patients with inadequately controlled asthma despite high-dose ICS plus LABAs were randomized to omalizumab or placebo for 48 wk. The primary endpoint was the rate of exacerbations over the study period. **Results**: The rate of protocol-defined asthma exacerbations were lower in omalizumab-treated patients than control patients (0.66% vs. 0.88%; P=0.006). The incidence of adverse events and serious adverse events were similar between groups. **Conclusions**: Addition of omalizumab in patients with uncontrolled severe allergic asthma reduces exacerbations and provides additional clinical benefits.
PATHWAY	NEJM 2017;377:936-46	**Title:** Tezepelumab in Adults with Uncontrolled Asthma **Purpose**: Evaluate the safety and efficacy of Tezepelumab, in patients with uncontrolled asthma despite LABA and medium-high ICS dose. **Methods**: Patients were randomized to Tezepelumab at three dose levels versus placebo over a 52-wk period. The primary endpoint was the annualized rate of asthma exacerbations. **Results**: Exacerbation rates in the Tezepelumab groups were lower by 62%, 71% and 66% than in the placebo group (P<0.001 for all comparisons). **Conclusions**: Among patients treated with LABA and medium-high doses of ICS, those who received Tezepelumab had lower rates of clinically significant asthma exacerbations than those who received placebo.
Novel START	NEJM 2019;380:2020-30	**Title:** Controlled Trial of Budesonide–Formoterol as Needed for Mild Asthma **Purpose**: Determine the efficacy of budesonide-formoterol versus SABAs in reducing asthma exacerbations. **Methods**: Patients with mild asthma were randomized to albuterol 100 µg, budesonide 200 µg plus albuterol prn, or budesonide-formoterol prn. The primary outcome was the annualized rate of asthma exacerbations. **Results**: The annualized exacerbation rate was lower in the combination group than in the albuterol group (0.195 vs. 0.400; RR 0.49; 95% CI 0.33 to 0.72; P<0.01). This did not differ significantly in the budesonide maintenance group (RR 1.12; 95% CI 0.70 to 1.79; P=0.65). The incidence of adverse events was consistent with previous trials. **Conclusions**: For the prevention of asthma exacerbations, budesonide-formoterol prn was superior to albuterol prn and did not differ significantly from budesonide maintenance.
PrimoTinA-asthma 1 and PrimoTinA-asthma 2	NEJM 2021;367:1198-1207	**Title:** Tiotropium in Asthma Poorly Controlled with Standard Combination Therapy **Purpose**: Determine the efficacy and safety of adding tiotropium bromide to a LABA and ICS combination treatment in the context of asthma. **Methods**: 912 adult patients from two randomized double-blind controlled trials were analyzed in the study. These participants, on LABA and ICS combination therapy, were randomly assigned to either the tiotropium or placebo group. Primary endpoint was FEV1 response and prevention of severe exacerbations. **Results**: The use of tiotropium resulted in better primary outcomes compared to placebo group as assessed by adjusted peak FEV1 (difference of 86mL; P=0.01 in trial 1 and 154mL; P<0.001 in trial 2) and time to first severe exacerbation (difference of 56 days). **Conclusions**: Tiotropium improved lung function and delayed severe exacerbations in patients with uncontrolled asthma when added to LABA and ICS treatment regimen.

Trial Name	Reference	Clinical Trial Details
SMART	Chest 2006; 129:15-26	**Title:** The Salmeterol Multicenter Asthma Research Trial: A Comparison of Usual Pharmacotherapy for Asthma or Usual Pharmacotherapy plus Salmeterol **Purpose**: Compare the safety of salmeterol xinafoate or placebo, when added to the usual asthma treatment regimen. **Methods**: Subjects with asthma without a history of LABA use were randomized to salmeterol 42 mg BID, or placebo BID via MDI. Results: The occurrence of the primary outcome, respiratory related deaths, or life-threatening experiences were not significantly different between salmeterol and placebo (50 vs. 36; RR 1.40; 95% CI 1.25 to 15.34). Subgroup analyses suggest that there is increased risk in African Americans compared with Caucasian subjects. **Conclusions**: Salmeterol added to usual asthma care increases the risk of respiratory-related and asthma-related deaths, particularly among African American patients reporting no baseline use of ICS.
CHRONIC OBSTRUCTIVE PULMONARY DISEASE		
IMPACT	NEJM 2018;378:1671-80	**Title:** Once-Daily Single-Inhaler Triple versus Dual Therapy in Patients with COPD **Purpose**: Assess the benefits of triple-therapy with ICS, LAMA and LABA, compared with dual therapy in COPD patients. **Methods**: 10355 patients with COPD were randomized to fluticasone-umeclidinium-vilanterol, fluticasone furoate-vilanterol or umeclidinium-vilanterol. The primary outcome was the annual rate of moderate-severe COPD exacerbations. **Results**: The rate of exacerbations was 0.91 per yr in the triple therapy group, compared with 1.07 per yr with fluticasone furoate-vilanterol group and 1.21 per yr in the umeclidinium-vilanterol group (rate ratio with triple-therapy 0.75; 95% CI 0.70 to 0.81; P<0.001). The annual rate of hospitalizations was 0.18 in the triple-therapy group compared with 0.19 in the umeclidinium-vilanterol group (rate ratio 0.66; 95% CI 0.56 to 0.78; P<0.001). **Conclusions**: Triple therapy with an ICS+LAMA+LABA resulted in a lower rate of moderate or severe COPD exacerbations than dual therapy.
FLAME	NEJM 2016;374:2222-34	**Title:** Indacaterol–Glycopyrronium versus Salmeterol–Fluticasone for COPD **Purpose**: Elucidate the role of a LAMA-LABA treatment regimen in COPD patients with a high risk of exacerbations. **Methods**: Patients with COPD and a history of >1 exacerbation in the prior year were randomized to incadeterol 100 µg plus glycopyrronium 50 µg, or salmeterol 50 µg plus fluticasone 500 µg. The primary outcome was the annual rate of all COPD exacerbations. **Results**: The rate of exacerbations was 11% lower in the indacaterol-glycopyrronium group relative the salmeterol-fluticasone group (3.59 vs. 4.03; rate ratio 0.89; 95% CI 0.83 to 0.96; P=0.003). The annual rate of moderate-severe exacerbations was lower in the indacaterol-glycopyrronium group than in the salmeterol-fluticasone group (0.98 vs. 1.19; rate ratio 0.83; 95% CI 0.75 to 0.91; P<0.001). **Conclusions**: LABA+LAMA regimen of indacaterol-glycopyrronium was more effective than a LABA+ICS regimen of salmeterol-fluticasone in preventing COPD exacerbations.
REDUCE	JAMA 2013;309:2223-31	**Title:** Short-term vs. Conventional Glucocorticoid Therapy in Acute Exacerbations of Chronic Obstructive Pulmonary Disease **Purpose**: To investigate whether a short-term systemic steroid treatment is noninferior to conventional treatment. **Methods**: 314 patients presenting to the ED with acute COPD exacerbations were randomized to prednisone 40 mg for either 5 (short-term) or 14 (conventional) d. The primary endpoint was the time for the next exacerbation in 180 d. **Results**: In the intention-to-treat analysis, hazard ratios between groups were 0.95 (95% CI 0.70 to 1.29; P=0.006). In the short-term group, 35.9% of patients reached the endpoint while 36.8% patients in the conventional group reached the endpoint. There was no difference between groups in time to death or recovery of lung function. **Conclusions**: A 5-d course of glucocorticoids is non-inferior to a 14-d course for treatment of acute COPD exacerbations.
POET-COPD	NEJM 2011;364:1093-103	**Title:** Tiotropium versus Salmeterol for the Prevention of Exacerbations of COPD **Purpose**: Investigate whether the LAAC tiotropium is superior to the LABA salmeterol in preventing COPD exacerbations. **Methods**: Patients with moderate-severe COPD and a history of exacerbations were randomized to tiotropium 18 µg OD or salmeterol 50 µg BID. The primary outcome was time to the first exacerbation during the study period. **Results**: Tiotropium, as compared with salmeterol, increased the time to first exacerbation, with a 17% risk reduction (hazard ratio 0.83; 95% CI 0.77 to 0.90; P<0.001). Tiotropium also reduced the number of moderate and severe exacerbations (0.64 vs. 0.72; rate ratio 0.89; 95% CI 0.83 to 0.96; P=0.002). **Conclusions**: Tiotropium decreases the number of moderate-to-severe COPD exacerbations in comparison to salmeterol.
ROFLUMILAST	Lancet 2009;374:695-703	**Title:** Roflumilast in Moderate-to-severe Chronic Obstructive Pulmonary Disease Treated with Long Acting Bronchodilators **Purpose**: Investigate the effect of phosphodiesterase-4 (PDE4) inhibitor roflumilast on lung function in COPD patients treated with salmeterol or tiotropium. **Methods**: Patients >40 yr with moderate-severe COPD were randomized to oral roflumilast 500 µg or placebo OD for 24 wk, in addition to salmeterol or tiotropium. The primary endpoint was a change in prebronchodilator FEV1. **Results**: Compared with placebo, treatment with roflumilast improved mean FEV1 by 49 mL (p<0.0001) in patients treated with salmeterol, and 80 mL (0.0001) in patients treated with tiotropium. Roflumilast had benefits on other measures of lung function in both groups. **Conclusions**: PDE4 inhibitor roflumilast improves FEV1 when used as add-on therapy in COPD patients on tiotropium or salmeterol.
UPLIFT	NEJM 2008;359:1543-54	**Title:** A 4-Year Trial of Tiotropium in Chronic Obstructive Pulmonary Disease **Purpose**: Examine the long-term effects of tiotropium therapy in patients with COPD. **Methods**: Patients with COPD, permitted to use all drugs except LAACs, were randomized to 4 yr of tiotropium or placebo. The primary endpoints were the rate of decline in FEV1 before and after bronchodilation. **Results**: Mean differences in FEV1 were maintained throughout the trial between the tiotropium and placebo groups (87-103 mL before bronchodilation; 47-65 mL after bronchodilation). The 30 d differences between groups were not significant. **Conclusions**: Tiotropium improves symptoms of COPD with fewer exacerbations, but does not affect FEV1 decline.
TORCH	NEJM 2007;356:775-89	**Title:** Salmeterol and Fluticasone Propionate and Survival in Chronic Obstructive Pulmonary Disease **Purpose**: Analyze the survival benefits of LABA and ICS in COPD patients. **Methods**: Patients with COPD were randomized to salmeterol 50 µg plus fluticasone propionate 500 µg BID, administered with a single placebo inhaler, salmeterol alone or fluticasone alone. The primary outcomes were all-cause mortality and the frequency of exacerbations. **Results**: All-cause mortality rates were 12.6% in the combination group, 15.2% in the placebo group, 13.5% in the salmeterol group and 16.0% in the fluticasone group (hazard ratio combination vs. placebo 0.825; 95% CI 0.681 to 1.002; P-0.052). Mortality in the salmeterol or fluticasone monotherapy group did not differ from placebo. **Conclusions**: Combination of ICS and LABAs improves COPD symptoms, reduces exacerbations, and shows a trend to lower mortality.

Trial Name	Reference	Clinical Trial Details
INTERSTITIAL LUNG DISEASE		
INBUILD	NEJM 2019; 381:1718-1727	**Title:** Nintedanib in Progressive Fibrosing Interstitial Lung Diseases **Purpose**: Evaluate the efficacy of Nintedanib across a broad range of progressive fibrosing lung diseases. **Methods**: Patients with significant, progressive fibrosing lung disease of any cause were randomized to Nintedanib 150 mg twice daily or placebo. The primary endpoint was the annual rate of decline in FVC. **Results**: 663 patients treated. The average annual rate of change in FVC was -80.8 mL in the Nintedanib group and -187.8 mL in the placebo group. Patients with UIP type pattern on imaging had a difference of -82.9 mL versus -211.1 mL favouring Nintedanib. **Conclusions**: In patients with progressive fibrosing interstitial lung diseases, Nintedanib reduced the annual rate of decline in FVC.
PANTHER	NEJM 2012; 366:1968-1977	**Title:** Prednisone, Azathioprine, and N-Acetylcysteine for Pulmonary Fibrosis **Purpose**: To evaluate the safety and efficacy of a three drug regimen (prednisone, azathioprine and N-acetylcysteine(NAC)) for IPF. **Methods**: Patients with mild to moderate IPF were randomized to the active drug combination, NAC alone or placebo. The primary endpoint was change in FVC. **Results**: The trial was terminated early when an interim analysis demonstrated that patients in the active drug combination arm had an increased rate of death (8 vs. 1) and hospitalization (23 vs. 7) when compared to placebo. No evidence of benefit was identified in any physiological measurements such as FVC. **Conclusions**: Patients with IPF treated with prednisone, azathioprine and NAC had increased risk of death and hospitalization when compared to no treatment.
INPULSIS	NEJM 2014;370:2071-82	**Title:** Efficacy and Safety of Nintedanib in Idiopathic Pulmonary Fibrosis **Purpose**: Evaluate the safety and efficacy of Nintedanib in patients with IPF. **Methods**: Patients with IPF were randomized to Nintedanib 150 mg twice daily or placebo. The primary endpoint was the annual rate of decline in FVC. **Results**: The annual rate of change in FVC was -114.7 mL with Nintedanib versus -239.9 mL with placebo (difference 125.3 mL; 95% CI 77.7 to 172.8; P<0.001) in INPULSIS-1. In INPULSIS-2, the same metric was -113.6 mL with Nintedanib versus -207.3 mL with placebo (difference 93.7 mL; 95% CI 44.8 to 142.7; P<0.001). There was a reduction in acute exacerbations of IPF in the treatment arms but no mortality difference. **Conclusions**: Nintedanib reduces the decline in FVC in patients with IPF.
ASCEND	NEJM 2014;370:2083-92	**Title:** A Phase 3 Trial of Pirfenidone in Patients with Idiopathic Pulmonary Fibrosis **Purpose**: Confirm the beneficial effects of pirfenidone on disease progression in patients with IPF. **Methods**: 555 patients with IPF were randomized to oral pirfenidone (2403 mg daily) or placebo for 52 wk. The primary endpoint was change in FVC or death at the study period. **Results**: There was a relative reduction of 47.9% in the proportion of patients with 10% decline in FVC, in the pirfenidone group compared to placebo (P<0.001). Pirfenidone improved progression-free survival (P<0.001). There was no significant difference in dyspnea scores (P=0.16), all-cause mortality (0.10) or IPF mortality (P=0.23) between groups. In a pooled analysis with prior trials, there was a reduction in mortality. **Conclusions**: Pirfenidone reduces disease progression in patients with IPF.
PULMONARY EMBOLISM		
EINSTEIN-PE	NEJM 2012;366:1287-97	**Title:** Oral Rivaroxaban for the Treatment of Symptomatic Pulmonary Embolism **Purpose**: Assess the effectiveness of fixed-dose rivaroxaban for the treatment of deep vein thrombosis (DVT). **Methods**: 4832 patients with acute symptomatic PE with-or-without DVT were randomized to rivaroxaban 15 mg BID or to standard therapy with enoxaparin followed by a vitamin-K antagonist. The primary outcome was symptomatic recurrent VTE. **Results**: Rivaroxaban was noninferior to standard therapy (P=0.003) for the primary outcome, with 2.1% and 1.8% event rates in the rivaroxaban and standard-therapy groups, respectively (hazard ratio 1.12; 95% CI 0.75 to 1.68). Major or non-major clinically relevant bleeding occurred in 10.3% of rivaroxaban-treated patients and 11.4% of patients receiving standard therapy (hazard ratio 0.90; 95% CI 0.76 to 1.07; P=0.23). **Conclusions**: Fixed dose of rivaroxaban was non-inferior to standard therapy (Vitamin K antagonist) for the initial and long-term treatment of PE.
EPSTEIN-CHOICE	NEJM 2017;376:1211-22	**Title:** Rivaroxaban or Aspirin for Extended Treatment of Venous Thromboembolism (EPSTEIN CHOICE) **Purpose**: To assess the efficacy of full- or lower-intensity anticoagulation therapy in the extended treatment of VTE. **Methods**: 3396 patients with VTE were randomized to receive either rivaroxaban 10 or 20 mg once daily, or 100 mg of ASA. All study patients had completed 6 to 12 mo of anticoagulation therapy and were in equipoise regarding the need for continued anticoagulation. The primary efficacy outcome was symptomatic recurrent fatal or nonfatal VTE, and the principal safety outcome was major bleeding. **Results**: The primary efficacy outcome occurred in 17 of 1107 patients (1.2%) receiving rivaroxaban, compared to 50 of 1131 patients (4.4%) receiving ASA (hazard ratio for 20 mg rivaroxaban vs. ASA 0.34; 95% CI 0.20 to 0.59; hazard ratio for 10 mg rivaroxaban vs. ASA 0.26; 95% CI 0.14 to 0.47; P<0.001 for all comparisons). The incidence of adverse events, including major and nonmajor clinically relevant bleeding, were similar among all groups. **Conclusions**: Among patients with VTE in equipoise for continued anticoagulation, the risk of a recurrent event was lower with rivaroxaban (10 or 20 mg) than with ASA, without a significant increased risk of adverse events.
OBSTRUCTIVE SLEEP APNEA		
CPAP and Central Sleep Apnea	NEJM 2005;353:2025-33	**Title:** Continuous Positive Airway Pressure for Central Sleep Apnea and Heart Failure **Purpose**: Test the effectiveness of CPAP on survival outcomes without heart transplantation, in patients with CHF and CSA. **Methods**: 258 patients with HF and CSA were randomized to CPAP or no-CPAP. Sleep studies were conducted, and the primary outcomes were ejection fraction (EF), exercise capacity and quality of life. **Results**: The CPAP group had greater reductions in the frequency of apneic episodes, greater increases in mean nocturnal 02 sat (1.6% vs. 0.4%; P<0.001) and EF (2.2% vs. 0.4; P=0.02). There were no differences in the number of hospitalizations or quality of life. **Conclusions**: CPAP ameliorates symptoms of sleep apnea but does not affect mortality in CHF.
SAVE	NEJM 2016;375:919-31	**Title:** CPAP for Prevention of Cardiovascular Events in Obstructive Sleep Apnea **Purpose**: To determine whether CPAP reduces cardiovascular events in patients with sleep apnea. **Methods**: 2687 participants recruited from 7 different countries were randomly assigned to receive either standard care or CPAP with standard care. Primary endpoints measured were death from cardiovascular cause, MI, stroke, or hospitalizations for CHF, acute coronary syndrome, or TIA. **Results**: There was no significant difference between the CPAP + standard care group and the standard care group in terms of cardiac events (HR 1.10, P=0.34). **Conclusions**: CPAP does not reduce the risk of cardiovascular events in patients with OSA.

Acronyms

AAV	antineutrophil cytoplasmic antibody-associated vasculitis	CMC	carpometacarpal joint	GPA	granulomatosis with polyangiitis	PsA	psoriatic arthritis
Ab	antibody	CNS	central nervous system	H/A	headache	PTT	partial thromboplastin time
ACPA	anti-citrullinated protein antibodies	CTD	connective tissue disease	Hb	hemoglobin	PUD	peptic ulcer disease
Ag	antigen	CPPD	calcium pyrophosphate deposition disease	HLA	human leukocyte antigen	RA	rheumatoid arthritis
ANA	antinuclear antibody	CRP	C-reactive protein	IA	intra-articular	ReA	reactive arthritis
ANCA	antineutrophil cytoplasmic antibody	CVA	cerebrovascular accident	IBD	inflammatory bowel disease	RF	rheumatoid factor
Anti-RNP	antiribonuclear protein	CVS	cardiovascular system	IE	infective endocarditis	ROM	range of motion
Anti-Sm	anti-Smith antibodies	DAT	direct antiglobulin test	ILD	interstitial lung disease	SI	sacroiliac
Anti-SRP	anti-signal recognition particle	DEXA	dual energy x-ray absorptiometry	IP	interphalangeal joint	SLE	systemic lupus erythematosus
Anti-SSA	anti-Sjögren's syndrome antigen A	DIP	distal interphalangeal joint	ITP	idiopathic thrombocytopenic purpura	SNRI	serotonin-norepinephrine reuptake inhibitors
APLA	antiphospholipid antibodies	DMARD	disease-modifying anti-rheumatic drug	MCP	metacarpophalangeal joint	SpA	spondyloarthritis
APS	antiphospholipid antibody syndrome	DMM	dermatomyositis	MCTD	mixed connective tissue disease	SS	Sjögren's syndrome
aPTT	activated partial thromboplastin time	dsDNA	double stranded DNA	MHC	major histocompatibility complex	SSA	Sjögren's syndrome antigen A
AS	ankylosing spondylitis	EA	enteropathic arthritis	MPA	microangiopathic polyangiitis	SSB	Sjögren's syndrome antigen B
AVN	avascular necrosis	ECASA	enteric-coated acetylsalicylic acid	MPO	myeloperoxidase	SSc	systemic sclerosis
BlyS	B-lymphocyte stimulator	EGPA	eosinophilic granulomatosis and polyangiitis	MTP	metatarsophalangeal joint	SSZ	sulfasalazine
BUN	blood urea nitrogen	ESR	erythrocyte sedimentation rate	MTX	methotrexate	TB	tuberculosis
CCB	calcium channel blocker	FVC	forced vital capacity	OA	osteoarthritis	TNF	tumour necrosis factor
CCP	cyclic citrullinated peptide	GC	*Neisseria gonorrhoeae gonococcus*	PAN	polyarteritis nodosa	TTP	thrombotic thrombocytopenic purpura
CK	creatine kinase	GCA	giant cell arteritis	PIP	proximal interphalangeal joint	ULN	upper limit of normal
				PM	polymyositis	U-SpA	undifferentiated spondyloarthropathy
				PMN	polymorphonuclear leukocyte	VDRL	venereal disease research laboratory
				PMR	polymyalgia rheumatica		
				PR3	proteinase 3		

Anatomy of Joint Pathology

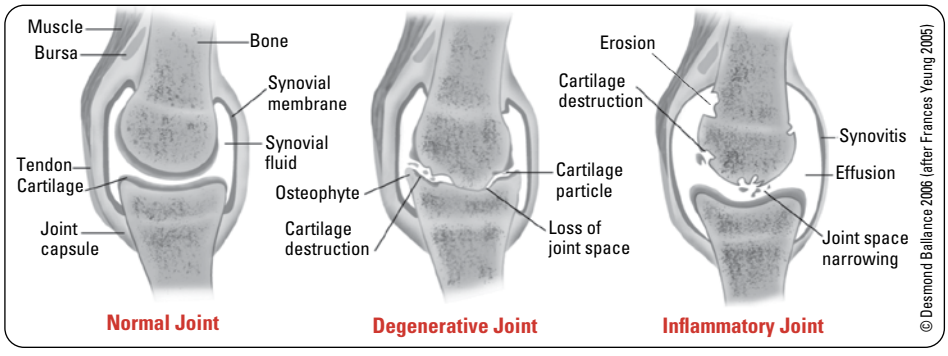

Figure 1. Structure of normal, degenerative, and inflammatory joint

Terminology in Rheumatology

Arthritis: inflammation in the joint(s)
- Joint swelling: effusion/synovial thickening
- Pain
- Warmth
- Erythema
- Arthralgia: joint pain without swelling, redness, or warmth

Basics of Immunology

Immune Mechanisms of Disease

Table 1. Mechanisms of Immune-Mediated Disorders

Type	Pathophysiology	Examples
IgE-Mediated/Immediate Hypersensitivity (Type I)	Allergens bind to IgE antibodies on mast cells, inducing their degranulation	Asthma, allergic rhinitis, anaphylaxis
Antibody-Mediated/Cytotoxic (Type II)	IgG or IgM antibodies deposit and bind to cell membrane- or matrix-associated antigen leading to lysis of the target cell	Autoimmune hemolytic anemia, anti-glomerular basement membrane disease (Goodpasture syndrome), Graves' disease, pemphigus vulgaris, rheumatic fever, ITP
Immune Complex (Type III)	Ag-Ab complexes deposit in tissues, which activates complement and recruits inflammatory mediators, resulting in tissue injury	SLE, PAN, post-streptococcal glomerulonephritis, serum sickness, viral hepatitis
Cell-Mediated/Delayed Hypersensitivity (Type IV)	Release of cytokines by sensitized T cells and T cell-mediated cytotoxicity	Contact dermatitis, insect venom, mycobacterial proteins (e.g. tuberculin skin test)

Innate Immune Cells
- **Neutrophil (PMN):** circulates in blood and responds to inflammatory stimuli, kills invading organisms by phagocytosis, degranulation, and neutrophil extracellular traps
- **Natural Killer Cell**: innate immunity against intracellular infections (especially viruses), killing function, and produces cytokines
- **Macrophage**: arrives after PMNs, suppresses PMN efflux and phagocytoses PMN debris, secretes pro-inflammatory cytokines in response to microbial debris
- **Dendritic Cell**: actively phagocytic when immature, activated by signals from toll-like receptor (TLR), releases pro-inflammatory cytokines, presents antigens to T cells in lymph nodes
- **Eosinophil**: responds to inflammatory cytokines and degranulates, releasing reactive oxygen species and cytokines, associated with allergy, asthma, and parasitic infection
- **Mast Cell**: presents in connective tissue and mucosa, allergen cross-linking of IgE bound to mast cell triggers degranulation and the release of inflammatory mediators

Immunogenetics and Disease

- the short arm of chromosome 6 contains the genes that encode HLA molecules
- in humans, HLAs act as MHCs which a) present antigens to be recognized by T-cell receptors and b) identify the self to the immune system such that they must be matched for in organ transplantation
- certain HLA haplotypes are associated with increased susceptibility to autoimmune diseases

Table 2. Classes of MHCs

MHC Class	Types	Location	Function
I	HLA-A, B, C	All nucleated cells	Recognized by CD8+ (cytotoxic) T lymphocytes
II	HLA-DP, DQ, DR	Ag presenting cells (mononuclear phagocytes, B cells, etc.)	Recognized by CD4+ (helper) T lymphocytes
III	Some components of the complement cascade	In plasma	Chemotaxis, opsonization, lysis of bacteria and cells

Table 3. HLA-Associated Rheumatic Diseases

HLA Type	Associated Conditions	Comments
B27	AS ReA EA (axial) PsA (axial)	Relative risk = 20x for developing AS and ReA
DR4, DR1	RA	In RA, relative risk = 2-10x; found in 93% of patients
DR3	SS SLE	DR3 is associated with the production of anti-Ro/SSA and anti-La/SSB antibodies

Differential Diagnoses of Common Presentations

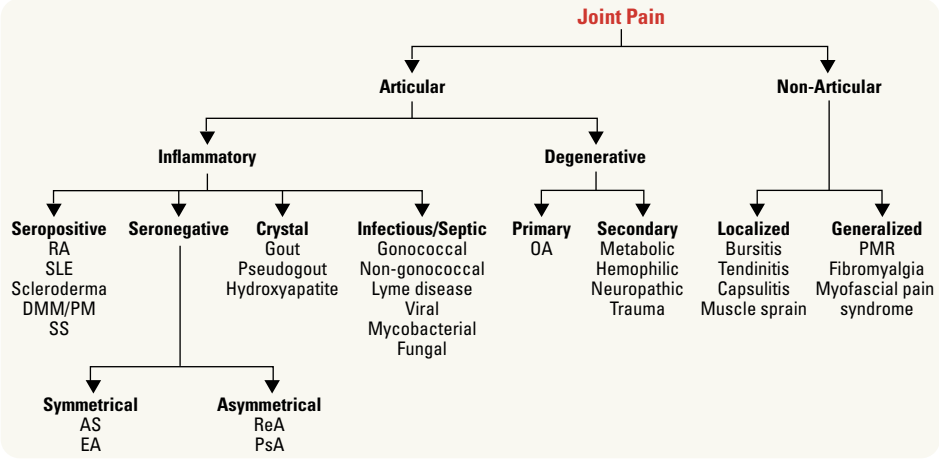

Figure 2. Clinical approach to joint pain

Table 4. Differential Diagnosis of Acute Monoarthritis

Non-Inflammatory	Inflammatory	
	Crystal-Induced	Infectious
Hemarthrosis, internal derangement (e.g. loose body, torn meniscus)	Monosodium urate (MSU-gout), CPPD/ pseudogout, hydroxyapatite	Gonococcal, nongonococcal, mycobacterial, and fungal

Key Cytokine Targets of Biologic Drugs

TNF
- **Source of cytokine**: T cells, macrophages/monocytes
- **Major functions**: apoptotic cell death, cachexia, induces other cytokines, T cell stimulation, induces metalloproteinases and prostaglandins, increases expression of adhesion molecules; increases vascular permeability, leading to increased entry of IgG, complement, and cells into tissues

Interleukin-6 (IL-6)
- **Source of cytokine**: many cells including monocytes and macrophages
- **Major functions**: anemia of inflammation (hepcidin production), proliferation of B and T cells, acute phase reactant, induces natural protease inhibitor, promotes erosions, induces elevated CRP

Adaptive Immune Cells
- **B cell:** produces antibodies after activation by specific antigen and B cell co-receptor, additional signals provided by CD4 T helper cells
- **Cytotoxic T cell**: CD8 cell, directs cytotoxicity of target cells at sites of infection, kills via lytic granules and FasL-Fas interaction, recognizes specific antigen and MHC I
- **Helper T cell**: subset of CD4 cells, activates and helps other types of cells carry out immune defense (activates macrophages, helps B cells, releases cytokines)
- **Regulatory T cell**: subset of CD4 cells, suppresses activation of naïve autoreactive T cells

Causes of Joint Pain

SOFTER TISSUE
Sepsis
OA
Fracture
Tendon/muscle
Epiphyseal
Referred
Tumour
Ischemia
Seropositive arthritides
Seronegative arthritides
Urate (gout)/other crystal
Extra-articular rheumatism (PMR/ fibromyalgia)

Patterns of Joint Involvement
- Symmetrical vs. asymmetrical
- Small vs. large
- Mono vs. oligo (2-4 joints) vs. polyarticular (≥5 joints)
- Axial vs. peripheral

Table 5. Differential Diagnosis of Oligoarthritis/Polyarthritis

Acute (<6 wk)	Chronic (>6 wk)		
Post-viral infection (parvovirus B19, HIV) Post-bacterial infection (GC and non-GC, rheumatic fever) Crystal-induced Other (sarcoidosis, Lyme disease) Very early rheumatoid arthritis (VERA)	**Seropositive inflammatory arthritis** RA SLE Scleroderma DMM/PM	**Seronegative inflammatory arthritis** AS EA PsA ReA Crystal (polyarticular gout)	**Degenerative** OA

Table 6. Symptoms of Inflammatory Arthritis vs. Degenerative Arthritis

Inflammatory	Degenerative
Pain at rest, relieved with activity Morning stiffness >1 h Cardinal signs of inflammation (warmth, swelling, erythema, tenderness, loss of function) Malalignment/deformity (late finding) Extra-articular manifestations Nighttime awakening due to pain	Pain with motion, relieved by rest Morning stiffness <1 h Joint instability, buckling, gelling Bony enlargement, malalignment/deformity (late finding) Evening/end of day pain

Table 7. Seropositive vs. Seronegative Rheumatic Diseases

	Seropositive	Seronegative
Demographics	F>M	M>F
Peripheral Arthritis	Symmetrical Small (PIP, MCP) and medium joints (wrist, knee, ankle, elbow) common DIP less often involved	Usually asymmetrical Usually larger joints, lower extremities (exception: PsA) DIP in PsA Dactylitis ("sausage digit")
Pelvic/Axial Disease	No (except for C-spine)	Yes
Enthesitis	No	Yes
Extra-Articular	Nodules Vasculitis Sicca Raynaud's phenomenon Rashes, internal organ involvement (lung, cardiac) Entrapment neuropathies (i.e. carpal tunnel syndrome)	Iritis (anterior uveitis) Oral ulcers Gastrointestinal Dermatological (psoriasis, nail pitting, onycholysis, or keratoderma) Genitourinary inflammation

The presence of synovitis often indicates articular as opposed to non-articular joint pain; synovitis presents with: soft tissue swelling, effusion, warmth, and stress pain (passive movement of the joint through its range, plus a little bit further)

Monitoring CRP vs. ESR
- CRP is more sensitive for inflammation than ESR
- CRP responds more quickly to changes in the clinical situation than ESR
- False negative and false positive results are more common with ESR
- ESR is increased by renal disease, female sex, older age, pregnancy, and other chronic diseases such as DM, multiple myeloma, and congestive heart failure
- ESR can be useful at detecting low-grade bone and joint infections and monitoring disease activity in CTDs such as SLE, PMR, and GCA
- Do not order ESR for acute inflammation

Enthesitis: inflammation of tendon or ligament at site of attachment to bone

Synovial Fluid Analysis

- synovial fluid is an ultrafiltrate of plasma plus hyaluronic acid; it lubricates joint surfaces and nourishes articular cartilage

Indications
- diagnostic: to clarify cause of inflammation; to analyze fluid for culture, crystal, and cell count to differentiate inflammatory vs. degenerative; septic vs. crystal-induced vs. hemarthrosis
- therapeutic: drainage of blood, purulent or tense effusions; corticosteroid injection in the absence of sepsis

Contraindications to Joint Aspiration or Injection
- absolute: open lesion or suspected infection of overlying skin or soft tissue
- relative: bleeding diathesis, thrombocytopenia, prosthetic joint

Synovial Fluid Analysis
- most important to assess the 3 Cs: cell count (WBC) and differential, culture and Gram stain, and crystal analysis
- other parameters to consider are listed in Table 8, RH5

Most Important Tests of Synovial Fluid

3 Cs
Culture and Gram stain
Cell count and differential
Crystal examination

Table 8. Synovial Fluid Analysis

Parameter	Normal	Non-Inflammatory	Inflammatory	Septic	Hemorrhagic
Colour	Pale yellow	Pale yellow	Pale yellow	Yellow to white	Red/brown
Clarity	Clear	Clear	Opaque	Opaque/purulent	Sanguinous
WBC/mm^3	<200	<2000	≥2000 (crystal-induced arthritis – often much higher than 2000)	>50000	Variable
% PMN	<25%	<25%	≥50%	>75%	Variable
Culture/Gram Stain	–	–	–	Usually positive	–
Examples		Trauma OA Neuropathy Hypertrophic – arthropathy	Seropositive Seronegative Crystal arthropathies	*S. aureus* Gram negative GC → difficult to culture (may have low WBC)	Trauma Hemophilia

Choosing Wisely Canada Recommendations

1. Do not order ANA as a screening test in patients without specific signs or symptoms of SLE or another CTD
2. Do not order an HLA-B27 unless spondyloarthritis is suspected based on specific signs or symptoms
3. Do not repeat DEXA scans more often than every 2 yr
4. Do not prescribe bisphosphonates for patients at low-risk of fracture
5. Do not perform whole body bone scans (e.g. scintigraphy) for diagnostic screening for peripheral and axial arthritis in the adult population
6. Do not prescribe opioids for management of chronic rheumatic diseases before optimizing the use of non-opioid approaches in pain management
7. Do not delay or avoid palliative symptom management and advance care planning for a patient with life-limiting rheumatic diseases because they are pursuing disease-directed treatment

Septic Arthritis

Definition
- invasion of the joint by an infectious agent
- septic arthritis is a medical emergency; it can lead to rapid joint destruction and has a 10-15% risk of mortality
- knee and hip are most commonly affected joints, with knee accounting for approximately 50% of cases
- poor prognostic factors: older age, immunocompromised, delay in treatment, previously damaged joint, joint prosthesis

Septic arthritis is a medical emergency; it leads to rapid joint destruction, and there is a 10-15% risk of mortality

Pathophysiology
- most commonly caused by hematogenous spread of bacterial infection (Gram-positive cocci > Gram-negative bacilli)

Risk Factors
- very young or very old age (>80 yr), portal of entry (IV drug use, hemodialysis), recent infection with STIs, RA (related to prior joint damage and immunosuppressed state of host), type 2 DM

Investigations
- synovial fluid analysis: WBC count with differential, crystal analysis, Gram stain, and culture (see Table 8)
- blood work: CBC and C&S
- ± endocervical, urethral, rectal, and oropharyngeal swabs (if gonococcal septic arthritis is suspected)
- ± plain x-ray to establish joint baseline and to monitor treatment

Treatment
- consider empiric IV antibiotic therapy until septic arthritis is excluded or until cultures come back to narrow antibiotic choice
- source control and joint decompression
- see Infectious Diseases, ID13 and Orthopaedic Surgery, *Septic Joint* OR11

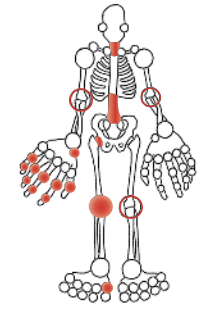
OA of MCPs can be seen in hemochromatosis or CPPD-related disease (chondrocalcinosis)

Degenerative Arthritis: Osteoarthritis

- see Family Medicine, FM44

Definition
- progressive deterioration of articular cartilage and surrounding joint structures caused by genetic, metabolic, biochemical, and biomechanical factors with secondary components of inflammation

Classification (Based on Etiology)
- primary (idiopathic)
  - most common, unknown etiology
- secondary
  - post-traumatic or mechanical
  - post-inflammatory (e.g. RA) or post-infectious
  - heritable skeletal disorders (e.g. scoliosis)
  - endocrine disorders (e.g. acromegaly, hyperparathyroidism, hypothyroidism)



- Hand (DIP, PIP, 1st CMC)
- Hip
- Knee
- 1st MTP
- L-spine (L4-L5, L5-S1)
- C-spine
- Uncommon: ankle, shoulder, elbow, MCP, rest of wrist

© Linda Colati

Figure 3. Common sites of joint involvement in OA

- metabolic disorders (e.g. gout, pseudogout, hemochromatosis, Wilson's disease, ochronosis)
- neuropathic (e.g. Charcot joints), atypical joint trauma due to peripheral neuropathy (e.g. DM, syphilis)
- AVN
- other (e.g. congenital malformation)

Pathophysiology

- the process appears to be initiated by abnormalities in biomechanical forces and/or, less often, in cartilage
- elevated production of pro-inflammatory cytokines is important in OA progression
- tissue catabolism > repair
- contributing factors (mechanisms unknown): genetics, alignment (bow-legged, knock-kneed), joint deformity (hip dysplasia), joint injury (meniscal or ligament tears), obesity, environmental, mechanical loading, age, and gender
- considered to be a systemic musculoskeletal disorder rather than a focal disorder of synovial joints

Epidemiology

- most common arthropathy (accounts for ~75% of all arthritides)
- increased prevalence with increasing age (35% of 30 y/o, 85% of 80 y/o)

Risk Factors

- genetic predisposition, advanced age, obesity (for knee and hand OA), female, trauma

Table 9. Signs and Symptoms of OA

Signs	Symptoms
Joint line tenderness; stress pain ± joint effusion	Joint pain with motion; relieved with rest
Bony enlargement at affected joints	Short duration of stiffness (<1/2 h) after immobility, called gelling
Malalignment/deformity (angulation)	Joint instability/buckling (often due to ligamentous instability)
Limited ROM	Joint locking due to "joint mouse" (bone or cartilage fragment)
Crepitus on passive ROM	Loss of function (e.g. meniscal tear or other internal derangements)
Inflammation (mild if present)	Insidious onset of pain, localized to affected joints
Periarticular muscle atrophy	Fatigue, poor sleep, impact on mood

Joint Involvement

- generalized OA: 3+ joint groups
- asymmetric (knees usually affected bilaterally)
- hand
  - DIP (Heberden's nodes = osteophytes ➡ enlargement of joints)
  - PIP (Bouchard's nodes)
  - CMC (usually thumb squaring)
  - 1st MCP (other MCPs are usually spared)
- hip
  - usually presents as groin pain ± dull or sharp pain in the trochanteric area, internal rotation and abduction are lost first
  - pain can radiate to the anterior thigh, but generally does not go below the knee
- knee
  - initial narrowing of one compartment, medial > lateral; seen on standing x-rays, often patellar-femoral joint involved
- foot
  - common in 1st MTP and midfoot
- lumbar spine
  - very common, especially L4-L5, L5-S1
  - degeneration of intervertebral discs and facet joints
  - reactive bone growth can contribute to neurological impingement (e.g. sciatica, neurogenic claudication) or spondylolisthesis (forward or backward movement of one vertebra over another)
- cervical spine
  - commonly presents with neck pain that radiates to scapula, especially in mid-lower cervical area (C5 and C6)

Investigations

- blood work
  - normal CBC and ESR, CRP
  - negative RF and ANA
- radiology: 4 hallmark findings, see sidebar
- synovial fluid: non-inflammatory (see Table 8, RH5)

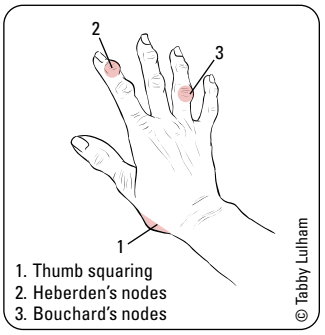


Figure 4. Hand findings in OA

Differential Diagnosis of Elevated ESR

- Systemic inflammatory diseases
- Localized inflammatory diseases
- Malignancy
- Trauma
- Infection
- Tissue injury/ischemia

The Radiographic Hallmarks of OA

- Joint space narrowing
- Subchondral sclerosis
- Subchondral cysts
- Osteophytes

Exercise for Osteoarthritis of the Knee: A Cochrane Systematic Review

Br J Sports Med 2015;49:1554-1557

Purpose: To determine if land-based therapeutic exercise is beneficial for people with knee OA in reducing pain, improving physical function, and improving quality of life.

Methods: Five databases searched for randomized clinical trials comparing therapeutic exercise with a non-exercise control.

Results: 54 studies identified. Results from 44 trials indicate that exercise significantly reduced pain (12 points/100; 95% CI 10 to 15) and improved physical function (10 points/100; 95% CI 8 to 13) after treatment. 13 studies showed improved quality of life with exercise. 12 studies showed reduced knee pain (6 points/100; 95% CI 3 to 19) and 10 studies showed improved physical function (3 points/100; 95% CI 1 to 5) with exercise.

Conclusion: In people with knee OA, land-based therapeutic exercise provides short-term benefit that is sustained a few mo after treatment.

Treatment

- presently, no treatment alters the natural history of OA
- prevention: prevent injury, weight management, physical activity (maintenance of muscle strength)
- non-pharmacological therapy
  - weight loss (minimum 5-10 lb loss) if overweight
  - exercise: more effective if supervised, often by physiotherapists or in a class setting; Tai chi is strongly recommended for hip/knee OA
  - self-efficacy and self-management programs (goal-setting, positive thinking, education on the disease)
  - thermal intervention: heat or cold
  - occupational therapy: aids, splints, cane, walker, bracing
- pharmacological therapy (see Table 34, RH33)
  - stepped approach to therapy (local → systemic therapy)
  - local therapy:
    - topical NSAIDs, topical capsaicin (knee, hand OA)
    - injections: IA glucocorticoids (knee, hip OA)
  - systemic therapy:
    - acetaminophen, oral NSAIDs
    - centrally acting agents (e.g. duloxetine)
  - the following are not recommended based on lack of high-quality evidence: opioids and medical cannabinoids (for pain), hyaluronates, platelet-rich plasma, stem cell injections, chondroitin, and glucosamine
- surgical treatment
  - total and/or partial joint replacement, joint debridement (not shown to be effective), osteotomy, fusion

Seropositive Rheumatic Disease

- diagnosis vs. classification in rheumatology
  - diagnostic criteria are selected for sensitivity, as opposed to specificity, thus may misdiagnose some cases
  - classification criteria are developed for specificity so well-defined cases can be studied in clinical trials
  - modern classification criteria are more sensitive and specific for diagnostic use in studies of earlier disease
- seropositive arthropathies are characterized by the presence of a serologic marker such as positive RF or ANA
- a small subset of the vasculitides (i.e. the small vessel ANCA-associated vasculitides) has a measurable serological component, but they are often considered a separate entity from seropositive disease by experts

Table 10. Autoantibodies and Their Prevalence in Rheumatic Diseases

Autoantibody	Disease	Healthy Controls	Comments
RF	RA 80% SS 50% SLE 20%	5-25%	Serologic hallmark of RA Autoantibodies directed against Fc domain of IgG Sensitive in RA (can be negative early in disease course) +RF is associated with more aggressive joint disease and extra-articular features (e.g. nodules) May be present in ANA-positive diseases, often in lower titre Non-specific; may be present in IE, TB, hepatitis C, silicosis, sarcoidosis
Anti-CCP	RA 80%		Specific for RA (94-98%) May be useful in early disease and to predict persistent and erosive disease, can occur before clinical disease becomes apparent
ANA	SLE 98% MCTD 100% SS 40-70% CREST 60-80% (Often seen in other CTDs)	High titres 1:640 <5% Low titres 1:40 Up to 30%, Prevalence of non-disease-related ANA rises with age	Ab against nuclear components (DNA, RNA, histones, centromere) Sensitive but not specific for SLE Given high false positive rate - only measure when high pre-test probability of CTD
Anti-dsDNA	SLE 50-70%	0%	Specific for SLE (95%) Levels correlate with disease activity (i.e. SLE flare)
Anti-Sm	SLE <30%	0%	Specific but not sensitive for SLE Does not correlate with SLE disease activity If positive, will remain positive through disease course
Anti-Ro (SSA)	SS 40-95% SSc 21% SLE 32% RA 15%	0.5%	Seen in SS Also seen in subacute cutaneous SLE (74%) May be the only Ab present in ANA-negative SLE Presence in pregnancy increases risk of having a child with neonatal lupus syndrome and congenital heart block

Note: some individuals in the normal population test positive for RF and/or ANA, but do not have the conditions listed above

Table 10. Autoantibodies and Their Prevalence in Rheumatic Diseases

Autoantibody	Disease	Healthy Controls	Comments
Anti-La (SSB)	SS 40% SLE 10%	0%	Usually occurs with anti-Ro Specific for SS and SLE when anti-Ro is also positive Increases risk of having a child with neonatal lupus syndrome
Antiphospholipid Ab (LAC, aCLA, aB2GP)	APS 100% SLE 31-40%	<5%	By definition, present in APS Only small subset of SLE patients develop clinical syndrome of APS If positive, will often get a false positive VDRL test
Anti-Histone	Drug-induced SLE 95% SLE 30-80%	0% 0%	Highly specific for drug-induced SLE
Anti-RNP	MCTD 20% SLE		High titres present in MCTD; present in many other CTDs (especially SLE)
Anti-Centromere	Limited SSc (CREST) >80%	0%	Specific for CREST, limited cutaneous variant of systemic sclerosis
Anti-Topoisomerase I (formerly Scl-70)	Diffuse SSc 26-76%	0%	Specific for SSc Increased risk for pulmonary fibrosis in SSc
Anti-Jo1	PM DMM	0%	Less frequent for DMM Associated with interstitial pulmonary fibrosis and anti-synthetase syndrome
c-ANCA	Active GPA 90% MPA 25% EGPA <5%	0%	Specific 80-95% for GPA and sensitive
p-ANCA	GPA 10% MPA 50-60% EGPA 50-70%	0%	Nonspecific and poor sensitivity (found in ulcerative colitis, PAN, microscopic polyangiitis, EGPA, rapidly progressive glomerulonephritis)
Anti-Mi-2	DMM 15-20%		Specific but not sensitive (not available in all centres)
Ab Against RBCs, WBCs, or Platelets	SLE		Perform DAT, test Hb, reticulocyte, leukocyte, platelet count, and antiplatelet Abs
Anti-Mitochondria	Primary biliary cholangitis	0%	Sensitive and specific

Note: some individuals in the normal population test positive for RF and/or ANA, but do not have the conditions listed above

Connective Tissue Disorders

Table 11. Features of Seropositive Arthropathies

	RA	SLE	Scleroderma	Dermatomyositis
CLINICAL FEATURES				
History	Symmetrical polyarthritis (small joint involvement) Morning stiffness (>1 h) Dyspnea on exertion (ILD) in <30%	Multisystem disease: rash, mouth ulcers, photosensitivity, Raynaud's, alopecia, cardiac and pulmonary serositis, CNS symptoms, glomerulonephritis	Skin tightness, stiffness of fingers, Raynaud's, heartburn, dysphagia, SOB on exertion due to pulmonary HTN or ILD, renal crisis with new onset HTN or hypertensive urgency/emergency	Heliotrope rash (periorbital), Gottron's papules (violaceous papules over knuckles and IPs) ± poikiloderma Shawl sign: photosensitivity, macular erythema over chest and shoulder Proximal muscle weakness > pain, dyspnea on exertion
Physical Examination	Early: effused joints, tenosynovitis, subcutaneous nodules, other extra-articular manifestations Late: joint deformities, bone-on-bone crepitus in advanced disease, inspiratory crackles	Check BP, rash, mouth ulcers, alopecia, Raynaud's phenomenon, serositis, ± effused (typically small) joints (can be minimal, look for soft tissue swelling)	Skin tightness on dorsum of hand, facial skin tightening, telangiectasia, calcinosis, non-effused joint, inspiratory crackles, features of right-side heart failure	Heliotrope rash, Gottron's papules, shawl sign, proximal muscle weakness (usually painless), inspiratory crackles
LABORATORY				
Non-Specific	↑ ESR in 50-60% ↑ CRP ↑ Platelets ↓ Hb (chronic disease) ↓ WBC (neutropenia rare)	↑ ESR ↓ Platelets (autoimmune) ↓ Hb (autoimmune) ↓ WBC (leukopenia, lymphopenia) ↑ Cr, proteinuria, RBC casts	↓ Hb Normal WBC Possibly ↑ Cr, proteinuria	↑ CRP ↓ Hb Normal WBC ↑CK
Specific	RF-positive in ~80% Anti-CCP-positive in ~80%	ANA-positive in 98%, Anti-dsDNA-positive in 50-70%, Anti-Sm-positive in 30%, ↓ C3, C4, total hemolytic complement, false positive VDRL (in SLE subtypes) APLA	ANA-positive in >90% Anti-topoisomerase 1 (diffuse) Anti-centromere (usually in CREST, see Sidebar, *CREST Syndrome*, RH15)	CK elevated in 80% ANA-positive in 33% Anti-Jo-1, anti-Mi-2 Muscle biopsy EMG MRI
Radiographs	Very early: normal Early: periarticular osteopenia Later: joint space narrowing Erosions Symmetric/concentric + ILD/lung nodules	Non-erosive ± Osteopenia ± Soft tissue swelling	± Pulmonary fibrosis/ILD ± Esophageal dysmotility ± Calcinosis	± Esophageal dysmotility ± ILD ± Calcifications

Rheumatoid Arthritis

Definition

- chronic, symmetric, erosive synovitis of peripheral joints (e.g. wrists, MCPs, MTPs)
- characterized by inflammatory joint disease ± a number of extra-articular features
- 1 joint with definite clinical synovitis (swelling) not explained by another disease

Table 12. 2010 ACR/EULAR Classification Criteria for RA
(score-based algorithm: add score of categories A-D; a score of 6/10 for definite RA)

Criteria	Score	Comments
A. Joint involvement (swollen or tender)		
1 large joint (shoulders, elbows, hips, knees, and ankles)	0	
2-10 large joints	1	
1-3 small joints (MCPs, PIPs, wrists, 2nd-5th MTPs)	2	
4-10 small joints	3	
>10 joints (at least 1 small joint)	5	
B. Serology		Total score of ≥6: definite RA Must have ≥1 joint with definite clinical swelling, not better explained by another disease
Negative RF and negative Anti-CCP	0	
Low-positive RF or low-positive Anti-CCP (<3x ULN)	2	
High-positive RF or high-positive Anti-CCP (>3x ULN)	3	
C. Acute phase reactants		
Normal CRP and normal ESR	0	
Abnormal CRP and abnormal ESR	1	
D. Duration of symptoms		
<6 wk	0	
≥6 wk	1	

Arthritis Rheum 2010;62:2569-2581

Pathophysiology

- autoimmune disorder, unknown etiology
- complex genetic and environment interactions lead to disruption of immune tolerance, ultimately resulting in synovial inflammation
  - genetic predisposition: HLA-DR4/DR1 association (93% of patients have either HLA type), cytokine promotors, T cell signaling
  - environmental predisposition: induction of enzymes that convert arginine to citrulline caused by environmental stress (cigarette smoking), propensity for immune reactivity to neoepitopes created by protein citrullination
- inflammatory process causes transformation of synovium into an invasive pannus tissue that degrades cartilage and bone with absence of repair
  - elevated TNF level increases osteoclasts and decreases osteoblasts at the site of inflammation (results in periarticular osteopenia)
  - upregulation of RANK ligand increases osteoclast-mediated destruction

Epidemiology

- most common inflammatory arthritis: prevalent in 1% of population
- F:M=3:1
- age of onset 20-40 yr

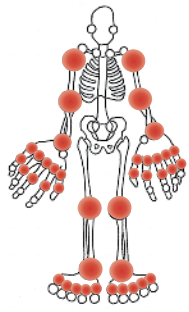
Signs and Symptoms

- variable course of exacerbations and remissions
- morning stiffness >1 h, improves with use, worsens with rest
- polyarthritis: symmetric joint involvement (tender, swollen), small joints affected, most commonly in hands and feet (MCP, PIP, MTP)
- constitutional symptoms: profound fatigue, depression, myalgia, weight loss
- extra-articular features
- limitation of function and decrease in global functional status
- complications of chronic synovitis
  - signs of mechanical joint damage: loss of motion, instability, deformity, crepitus, joint deformities
    - swan neck deformity, boutonnière deformity
    - ulnar deviation and subluxation of MCP, radial deviation of wrist joint
    - hammer toe, mallet toe, claw toe
    - flexion contractures
  - atlanto-axial and subaxial subluxation
    - C-spine instability
      - neurological impingement (long tract signs)
      - difficult/dangerous intubation: risk of worsening subluxation and damage to spinal cord

RA is an independent risk factor for atherosclerosis and CV disease. RA is associated with increased overall mortality/morbidity from all causes: CV disease, neoplasm (especially lymphoma), infection

Common Presentation

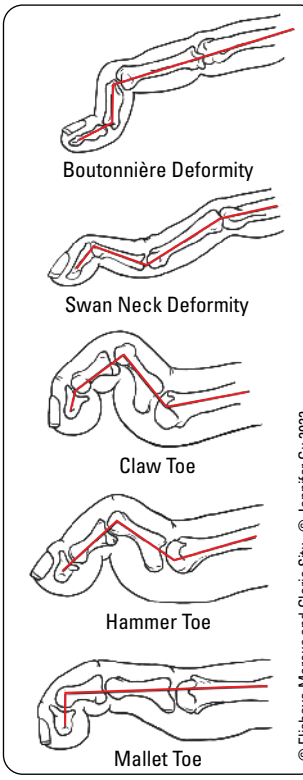
- Morning stiffness >1 h, improves with use
- Symmetric joint involvement
- Initially involves small joints of hands and feet
- Constitutional symptoms



- PIP
- MCP
- Wrist, not 1st CMC
- Elbow
- Shoulder
- Knee
- Ankle
- MTP
- C-spine

© Linda Colati

Figure 5. Common sites of joint involvement in RA



© Elisheva Marcus and Gloria Situ © Jennifer Gu 2022

Figure 6. Joint deformities

- limited shoulder mobility, spontaneous tears of the rotator cuff leading to chronic spasm
- tenosynovitis ➔ may cause rupture of tendons
- carpal tunnel syndrome
- ruptured Baker's cyst (outpouching of synovium behind the knee); presentation similar to acute deep vein thrombosis (DVT)
- poor prognostic factors include: young age of onset, high RF titre, elevated ESR, activity of >20 joints, and presence of extra-articular features

Table 13. Extra-Articular Features of RA Classified by Underlying Pathophysiology

System	Vasculitic	Lymphocytic Infiltrate
Skin	Periungual infarction, cutaneous ulcers, palpable purpura	Rheumatoid nodules (may have vasculitic component)
Ocular	Episcleritis, scleritis	Keratoconjunctivitis sicca
Head and Neck		Xerostomia, Hashimoto's thyroiditis (see Endocrinology, E32)
Cardiac		Peri-/myocarditis, valvular disease, conduction defects
Pulmonary		Pulmonary fibrosis, pleural effusion, pleuritis, pulmonary nodules
Neurologic	Peripheral neuropathy: sensory stocking-glove, mononeuritis multiplex	
Hematologic		Splenomegaly, neutropenia (Felty's syndrome)
Renal		Amyloidosis – caused by accumulation of abnormal proteins

Syndromes in RA
- SS (common): keratoconjunctivitis sicca and xerostomia (dry eyes and mouth)
- Caplan's syndrome (very rare): combination of RA + pneumoconiosis that manifests as multiple intrapulmonary nodules
- Felty's syndrome (rare): arthritis, splenomegaly, neutropenia

Classification of Global Functional Status in RA
- **Class I**: able to perform usual activities of daily living (self-care, vocational, avocational)
- **Class II**: able to perform self-care and vocational activities, restriction of avocational activities
- **Class III**: able to perform self-care, restriction of vocational and avocational activities
- **Class IV**: limited ability to perform self-care, vocational, and avocational activities

Investigations
- blood work
  - RF: 80% sensitivity but non-specific; may not be present at onset of symptoms; levels do not correlate with disease activity
    - can be associated with more erosions, more extra-articular manifestations, and worse function
  - anti-CCP: 80% sensitivity but more specific (94-98%); may precede onset of symptoms
- increased disease activity is associated with decreased Hb (anemia of chronic disease) and increased platelets, ESR, and CRP
- imaging
  - bilateral hands/wrists, ankles/feet x-ray
    - first change is periarticular osteopenia, followed by erosions
  - C-spine x-ray (may be normal at onset, required for preoperative assessment in long-standing disease)
  - U/S (with power Doppler) – often changes of synovitis/erosion noted in advance of those seen on plain x-ray
  - MRI may be used to image hands to detect early synovitis and erosions
  - MRI T1 inflamed synovium is hypointense and hyperintense on T2; bone marrow edema can be seen as well as areas of increased uptake gadolinium contrast

Poor prognostic features of RA include: young age of onset, high RF titre, elevated ESR, activity of >20 joints, and presence of extra-articular features

Side Effects of Steroids
- Weight gain
- Osteoporosis
- AVN
- Cataracts, glaucoma
- PUD
- Susceptibility to infection
- Easy bruising
- Acne
- HTN
- Hyperlipidemia
- Hypokalemia, hyperglycemia
- Mood swings

Treatment
- goals of therapy: remission or lowest possible disease activity
  - key is early diagnosis and early intervention with DMARDs
  - "window of opportunity" = early treatment within first 3 mo of disease may allow better control/remission
  - assess poor prognostic factors at baseline (RF-positive, functional limitations, and extra-articular features)
- behavioural
  - exercise program: active, gentle ROM and isometric exercise during flares; aquatic/aerobic/strengthening exercise between flares
  - job modification, assistive devices as necessary
  - interventions to reduce cardiovascular disease, smoking cessation, lipid control
- pharmacologic: alter disease progression
  - DMARDs and biologics (not analgesics or NSAIDs) can alter the course of RA
  - DMARDs
    - treatment with DMARDs should be started as soon as RA diagnosis is made, and should be aimed at reaching sustained remission

DMARDs, prednisone, and biologics, but not analgesics or NSAIDs, alter the course of RA

- MTX is the gold standard and is first-line unless contraindicated
  - prior to MTX therapy: CBC profile, liver enzymes (ALT), Cr (Cr clearance), hepatitis B and C serology, and a CXR should be done
  - monitor and if inadequate response (3-6 mo) → combine or switch
  - consider combination therapy to MTX if patients have poor prognostic features or high disease activity
  - therapy includes: hydroxychloroquine, SSZ, leflunomide, biologics
  - if contraindication to MTX, hydroxychloroquine, SSZ, and/or leflunomide should be considered with the former being considered as a weaker agent and the latter as more potent
- biologics (bDMARDs)
  - should be used if inadequate response to DMARDs
  - should be combined with DMARD therapy (initiating with combination therapy is associated with faster response rates and longer duration of effect)
  - first-line (anti-TNF) options: infliximab, etanercept, adalimumab, golimumab, and certolizumab
  - non-anti-TNF agents include anakinra (almost never used for RA), abatacept, rituximab, and tocilizumab
  - reassess every 3-6 mo and monitor disease activity (predominantly via assessing swollen joint count)
  - tofacitinib (Jak inhibitor) is technically a synthetic DMARD used if other DMARDs fail
- pharmacologic: supportive to reduce inflammation and pain
  - NSAIDs
    - individualize according to efficacy, tolerability, and comorbidities
    - contraindicated/cautioned in some patients (e.g. PUD, ischemic cardiac disease, pregnancy, CKD, anticoagulant use)
    - add acetaminophen for synergistic pain control
  - corticosteroids
    - local: injections to control symptoms in a specific joint
    - systemic (oral prednisone) or IM
      - low dose (5-10 mg/d) useful for short-term to improve symptoms if NSAIDs are ineffective and to bridge gap until DMARDs take effect
      - do baseline DEXA bone density scan and consider bone supportive pharmacologic therapy (e.g. bisphosphonates) if using corticosteroids 7.5 mg/d >3 mo, particularly in those with other risk factors
      - cautions/contraindications: active infection, TB, osteoporosis, HTN, gastric ulcer, DM
- surgical
  - indicated for structural joint damage
  - surgical options include: synovectomy, joint replacement, joint fusion, reconstruction/tendon repair

Follow-Up Management and Clinical Outcomes

- clinical reassessment every mo initially, then 3-6 mo if still ongoing activity, then 6-12 mo after inflammation has been suppressed
- examine joints for active inflammation – if active, consider adjusting medications, physical therapy/occupational therapy (PT/OT)
- RA patients should be screened and managed for cardiovascular disease given increased risk
- if assessment reveals joint damage – consider analgesia, referral to PT/OT, surgical options
- outcome depends on disease activity, joint damage, physical functional status, psychological health, and comorbidities
- functional capacity is a useful tool for determining therapeutic effectiveness; many tools for evaluation have been validated
- patients with RA have an increased prevalence of other serious illnesses: infection (e.g. pulmonary, skin, joint), osteoporosis, mental health disorders, renal impairment, lymphoproliferative disorders, cardiovascular disease (correlates with disease activity and duration)
- risk of premature mortality, decreased life expectancy (most mortality not directly caused by RA)

Systemic Lupus Erythematosus

- see Nephrology, NP26

Definition

- chronic autoimmune disease of unknown etiology resulting in multi-system inflammation
- characterized by production of autoantibodies and diverse clinical manifestations

Diagnostic Criteria of SLE

MD SOAP BRAIN
Malar rash
Discoid rash
Serositis
Oral ulcers
ANA
Photosensitivity
Blood
Renal
Arthritis
Immune
Neurologic

Table 14. Classification Criteria of SLE*

Entry criterion: ANA at a titre of ≥1:80 and Additive Criteria
1. Do not count criterion if there is a more likely explanation than SLE
2. Occurrence of a criterion on at least one occasion is sufficient
3. Within each domain, only the highest weighted criterion is counted towards the total score

Clinical Domains and Criteria		Score
Constitutional	Fever	2
Hematologic	Leukopenia	3
	Thrombocytopenia	4
	Autoimmune hemolysis	4
Neuropsychiatric	Delirium	2
	Psychosis	3
	Seizure	5
Mucocutaneous	Non-scarring alopecia	2
	Oral ulcers	2
	Subacute cutaneous OR discoid lupus	4
	Acute cutaneous lupus	6
Serosal	Pleural or pericardial effusion	5
	Acute pericarditis	6
Musculoskeletal	Joint involvement	6
Renal	Proteinuria (>0.5 g/24 h)	4
	Renal biopsy Class II or V lupus nephritis	8
	Renal biopsy Class III or IV lupus nephritis	10
Immunology Domains and Criteria		**Score**
Antiphospholipid antibodies	Anti-cardiolipin antibodies OR Anti-β2PG1 antibodies OR lupus anticoagulant	2
Complement proteins	Low C3 OR low C4	3
	Low C3 AND low C4	4
SLE specific antibodies	Anti-dsDNA OR Anti-Sm antibodies	6

*Classification of SLE requires total score of ≥10 with ≥1 clinical criterion
Sindhu R. Johnson, Thomas Dörner, Ray Naden, et al. Arthritis & Rheumatology (71, 9), p. 1400, copyright © 2020, Modified by Permission of John Wiley and Sons

A Systematic Review of Guidelines for Managing Rheumatoid Arthritis
BMC Rheumatol 2019;3:42
Five general principles for management:
- Start DMARDs as soon as possible following the diagnosis.
- The best initial treatment is MTX.
- Monitor disease activity regularly.
- Biologics should be initiated in patients with persistently active disease despite MTX treatment.
- Goals of treatment should be aimed at low disease activity or remission.

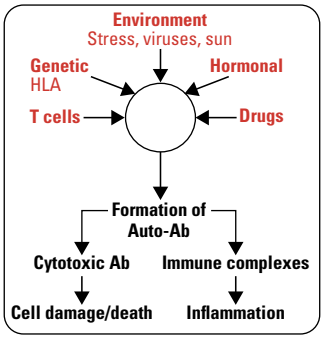


Figure 7. Multi-factorial etiology of SLE

Etiology and Pathophysiology

- production of cytotoxic autoantibodies and immune complex formation
- multi-factorial etiology
- **genetics**
  - common association with HLA-B8/DR3; ~10% have positive family history
  - strong association with defects in apoptotic clearance ➡ fragments of nuclear particles captured by antigen-presenting cells ➡ develop ANAs
  - cytokines involved in inflammatory process and tissue injury: B-lymphocyte stimulator (BlyS), IL-6, IL-17, IL-18, TNF-α
- **environment**
  - UV radiation, cigarette smoking, infection, vitamin D deficiency, silica dust
- **estrogen**
  - increased incidence after puberty, decreased incidence after menopause
  - men with SLE have higher concentration of estrogenic metabolites
  - increased risk of SLE associated with use of combined oral contraceptive pills and hormone replacement therapy
- **infection**
  - viral (non-specific stimulant of immune response)
- **drug-induced**
  - antihypertensives (hydralazine), anticonvulsants (phenytoin), antiarrhythmics (procainamide), isoniazid, biologics
  - anti-histone Abs are commonly seen in drug-induced SLE
  - symptoms resolve with discontinuation of offending drug

Drug-Induced SLE
Often presents atypically with systemic features and serositis; usually associated with anti-histone Ab

Epidemiology

- prevalence: 0.05% overall
- F:M=10:1
- age of onset in reproductive yr (15-45)
- more common and severe in Hispanic and Asian individuals, and individuals of African descent
- bimodal mortality pattern
  - early (within 2 yr)
    - active SLE, active nephritis, infection secondary to steroid use
  - late
    - inactive SLE, inactive nephritis, atherosclerosis likely due to chronic inflammation

Signs and Symptoms

- characterized by periods of flares and remission

Table 15. Signs and Symptoms of SLE

System	Symptoms
Systemic	Fatigue, malaise, weight loss, fever, lymphadenopathy
Hematologic	Anemia of chronic disease, hemolytic anemia, leukopenia, neutropenia, thrombocytopenia, pancytopenia, thrombosis, splenomegaly
Renal	Hematuria, proteinuria (glomerulonephritis), HTN, peripheral edema, renal failure
Dermatologic	Photosensitivity, malar rash, discoid rash, oral ulcers, alopecia (hair loss), purpura, panniculitis (inflammation of subcutaneous fat and muscle tissue), urticaria
Musculoskeletal	Polyarthralgias, polyarthritis, myalgias, AVN; reducible deformities of hand = Jaccoud's arthritis
Ophthalmic	Keratoconjunctivitis sicca, episcleritis, scleritis, cytoid bodies (cotton wool exudates on fundoscopy = infarction of nerve cell layer of retina)
Cardiac	Pericarditis, CAD, non-bacterial endocarditis (Libman-Sacks), myocarditis Note: SLE is an independent risk factor for atherosclerosis and CAD
Vascular	Raynaud's phenomenon, livedo reticularis (mottled discolouration of skin due to narrowing of blood vessels, characteristic lacy or net-like appearance), vasculitis
Respiratory	Pleuritis, ILD, pulmonary HTN, PE, alveolar hemorrhage
Gastrointestinal	Pancreatitis, SLE enteropathy, hepatitis, hepatomegaly, dysphagia, esophagitis, intestinal pseudo-obstruction, peritonitis, mesenteric vasculitis
Neurologic/Psychiatric	H/A, depression, psychosis, seizures, cerebritis, transverse myelitis, peripheral neuropathy, stroke
Life/Organ-Threatening	Cardiac: coronary vasculitis, malignant HTN, tamponade Hematologic: hemolytic anemia, neutropenia, thrombocytopenia, TTP, thrombosis Neurologic: seizures, CVA, stroke Respiratory: pulmonary HTN, pulmonary hemorrhage, emboli

Raynaud's Phenomenon
Vasospastic disorder characteristically causing discolouration of fingers and toes (white → blue → red)
Classic triggers: cold and emotional stress

Investigations

- ANA (98% sensitivity, but poor specificity → used as a screening test; ANA titres are not useful to follow disease course, see *Choosing Wisely Recommendations*, RH5)
- anti-dsDNA and anti-Sm are specific (95-99%)
- anti-dsDNA titre and serum complement (C3, C4) are useful to monitor treatment response in patients who are clinically and serologically concordant (anti-dsDNA increases, C3 and C4 decrease with disease activity)
- antiphospholipid Ab (anti-cardiolipin Ab, SLE anticoagulant, anti-β2 glycoprotein-I Ab), may cause increased risk of clotting and increased aPTT

Consider SLE in a patient who has involvement of 2 or more organ systems

Treatment

- **goals of therapy**
  - aim for remission, prevention of flares
  - hydroxychloroquine ± glucocorticoid
  - treat early and avoid long-term steroid use, if unavoidable see Endocrinology, E47 for osteoporosis management
  - if high doses of steroids are necessary for long-term control, taper when possible and add immunosuppressive therapies (MTX, azathioprine, mycophenolate)
  - treatment is tailored to organ system involved and severity of disease
  - moderate refractory disease can be treated with belimumab
  - all medications used to treat SLE require periodic monitoring for potential toxicity
- **dermatologic**
  - sunscreen, avoid UV light and estrogens
  - topical steroids, hydroxychloroquine
- **musculoskeletal**
  - NSAIDs ± gastroprotective agent for arthritis (also beneficial for pleuritis and pericarditis)
  - hydroxychloroquine improves long-term control and prevents flares
  - bisphosphonates, calcium, vitamin D to combat osteoporosis
- **other considerations**
  - smoking cessation
  - immunizations (influenza); live vaccines are generally not recommended
  - for women with anti-phospholipid antibodies, avoid estrogen-containing contraceptives because of increased risk of thrombosis
- **organ-threatening disease**
  - high-dose oral prednisone or IV methylprednisolone in severe disease
  - steroid-sparing agents: azathioprine, MTX, mycophenolate (can use mofetil or sodium)
  - IV cyclophosphamide for serious organ involvement (e.g. cerebritis or lupus nephritis) for clinical features of lupus nephritis
  - refractory disease can be treated with rituximab

The arthritis of SLE can be deforming but it is non-erosive (in contrast to RA) – called Jaccoud's arthritis

Antiphospholipid Antibody Syndrome

Definition

- multi-system vasculopathy manifested by recurrent thromboembolic events, spontaneous abortions, and thrombocytopenia
- circulating antiphospholipid autoantibodies interfere with coagulation
- primary APS: occurs in the absence of other disease
- secondary APS: occurs in the setting of a connective tissue disease (including SLE), malignancy, drugs (hydralazine, procainamide, phenytoin, interferon, quinidine), and infections (HIV, TB, hepatitis C, infectious mononucleosis)
- catastrophic APS: development within 1 wk of small vessel thrombotic occlusion in ≥3 organ systems with positive APLA (high mortality)

Table 16. Classification Criteria of APS*

Criteria	Description
CLINICAL	
Vascular thrombosis	One or more clinical episodes of arterial, venous, or small vessel thrombosis in any tissue or organ Must be confirmed by imaging or histopathology
Pregnancy morbidity	1. ≥1 death of morphologically normal fetus (confirmed by U/S or fetal exam) at ≥10 wk gestation; OR 2. ≥1 premature birth of morphologically normal neonate before 34 wk gestation due to eclampsia, preeclampsia, or placental insufficiency; OR 3. ≥3 consecutive spontaneous abortions <10 wk gestation (excluding maternal anatomic and hormonal abnormalities or paternal/maternal chromosomal causes)
LABORATORY	Labs must be positive on 2 occasions, at least 12 wk apart
Lupus anticoagulant	Present in plasma, detected according to the guidelines of the International Society on Thrombosis and Haemostasis
Anti-cardiolipin Ab	IgG and/or IgM, plasma or serum, present in medium-high titre (i.e. >40 GPL or MPL, or >99th percentile), measured by ELISA
Anti-β2 glycoprotein-I Ab	IgG and/or IgM, plasma or serum, present in high titre (i.e. >99th percentile), measured by ELISA

* 1 clinical and 1 laboratory criteria must be present
J Thromb Haemost 2006;4:295-306

Signs and Symptoms

- see clinical criteria (Table 16)
- hematologic
  - thrombocytopenia, hemolytic anemia, neutropenia
- dermatologic
  - livedo reticularis, Raynaud's phenomenon, purpura, leg ulcers, and gangrene

Treatment

- thrombosis
  - lifelong anti-coagulation with warfarin
  - target INR 2.0-3.0 for first venous event, >3.0 for recurrent event, target INR >3.0 for arterial event, or target INR 2.0-3.0 + ASA
- recurrent fetal loss
  - heparin/low molecular weight heparin ± ASA during pregnancy
- catastrophic APS
  - high-dose steroids, anti-coagulation, cyclophosphamide, plasmapheresis

Manifestations of APLA
- Thromboembolic events
- Spontaneous abortions
- Thrombocytopenia
- Associated with livedo reticularis, migraine headaches

Arterial and venous thrombosis are usually mutually exclusive

Anifrolumab: A potential future treatment option
Trial of Anifrolumab in Active Systemic Lupus Erythematosus (TULIP-2)
NEJM 2020;382:211-21
Purpose: To investigate the efficacy of anifrolumab for the treatment of SLE.
Methods: 362 patients were randomly assigned to receive either IV anifrolumab (300 mg) or placebo every 4 wk for 48 wk.
Primary Outcome: Response at wk 52 defined by the British Isles Lupus Assessment Group (BILAG)-based Composite Lupus Assessment (BICLA).
Results: A BICLA response was observed in 47.8% of patients on anifrolumab vs. 31.5% on placebo (difference, 16.3%; 95% CI, 6.3 to 26.3; P=0.001). Anifrolumab also improved glucocorticoid dose and the severity of skin disease.
Conclusion: In patients with SLE, monthly administration of anifrolumab was associated with improved clinical responses at wk 52 as compared to placebo.

Scleroderma (i.e. Systemic Sclerosis)

Definition

- a non-inflammatory autoimmune disorder characterized by widespread small vessel vasculopathy, production of autoantibodies, and fibroblast dysfunction causing fibrosis

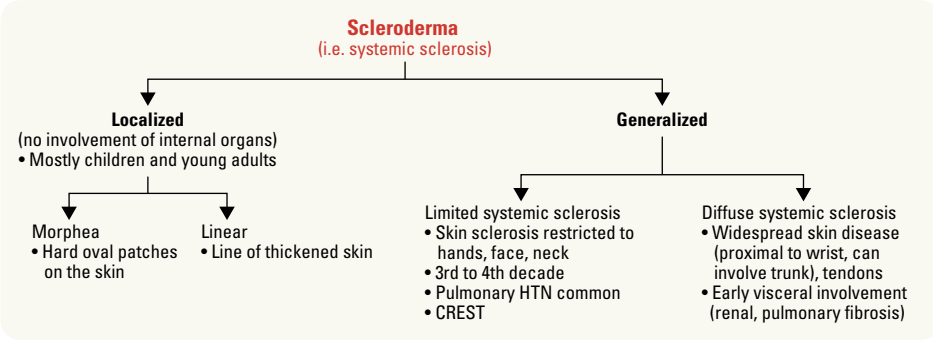

Figure 8. Forms of scleroderma

Etiology and Pathophysiology

- idiopathic vasculopathy (not vasculitis) leading to atrophy and fibrosis of tissues
  - characterized by several hallmark pathogenic features: small vessel vasculopathy resulting in tissue hypoxia, production of autoantibodies, and fibroblast dysfunction leading to increased deposition of extracellular matrix
  - resembles malignant HTN
  - lung disease is the most common cause of morbidity and mortality

Table 17. The American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) Criteria for the Classification of Scleroderma*

Item	Sub-item	Score
1. Skin thickening of fingers of both hands extending proximal to the MCP (sufficient criterion)		9
2. Skin thickening of the fingers	Puffy fingers Sclerodactyly	2
3. Fingertip lesions	Digital tip ulcers Fingertip pitting scars	4
4. Telangiectasia		2
5. Abnormal nailfold capillaries		3
6. Pulmonary arterial HTN ± ILD (max score 2)	Pulmonary arterial HTN ILD	2
7. Raynaud's phenomenon		2
8. Scleroderma-related Ab	Anti-centromere Anti-topoisomerase I Anti-RNA polymerase III	2

* Score of ≥9 is sufficient to classify a patient as having definite scleroderma (sensitivity 0.95, specificity 0.93)

Epidemiology

- F:M=3-4:1, peaking in 5th decade
- associated with HLA-DR1 and environmental exposures (silica, epoxy resins, toxic oil, aromatic hydrocarbons, polyvinyl chloride)
- limited systemic sclerosis has a higher survival prognosis (>70% at 10 yr) than diffuse systemic sclerosis (40-60% at 10 yr)

CREST Syndrome
Calcinosis
Raynaud's phenomenon
Esophageal dysmotility
Sclerodactyly
Telangiectasia

Scleroderma is the most common cause of secondary Raynaud's phenomenon

Cyclophosphamide vs. Mycophenolate Mofetil in Scleroderma Lung Disease
Lancet Respir Med 2016;4:708-719
Study: Double-blind, randomized, parallel group trial.
Purpose: To compare the toxicity and efficacy of cyclophosphamide vs. mycophenolate mofetil on lung function.
Results: In both treatment groups, the adjusted percent predicted FVC improved from baseline to 24 mo. Mycophenolate mofetil was associated with less toxicity and was better tolerated.
Conclusion: Treatment of SSc-ILD with mycophenolate mofetil for 2 yr or cyclophosphamide for 1 yr both result in improved lung function. However, mycophenolate mofetil is the current preference for treatment of SSc-ILD due to its better tolerability.

Raynaud's Phenomenon DDx

COLD HAND
Cryoglobulins/Cryofibrinogens
Obstruction/Occupational
Lupus erythematosus, other connective tissue disease
DM/Drugs
Hematologic problems (polycythemia, leukemia, etc.)
Arterial problems (atherosclerosis)/Anorexia nervosa
Neurologic problems (vascular tone)
Disease of unknown origin (idiopathic)

Signs and Symptoms

Table 18. Clinical Manifestations of Scleroderma

System	Features
Dermatologic	Painless non-pitting edema → skin tightening Ulcerations, calcinosis, periungual erythema, hypo/hyperpigmentation, pruritus, telangiectasias Characteristic face: mask-like facies with tight lips, beak nose, radial perioral furrows
Vascular	Raynaud's phenomenon → digital pits, gangrene Thrombosis
Gastrointestinal (~90%)	Distal esophageal hypomotility → dysphagia Loss of lower esophageal sphincter function → gastroesophageal reflux disease (GERD), ulcerations, strictures Small bowel hypomotility → bacterial overgrowth, diarrhea, bloating, cramps, malabsorption, weight loss Large bowel hypomotility → wide mouth diverticula are pathognomonic radiographic finding on barium study
Renal	Mild proteinuria, Cr elevation, HTN "Scleroderma renal crisis" (10-15%) may lead to malignant arterial HTN, oliguria, and microangiopathic hemolytic anemia
Pulmonary (~80%)	Interstitial fibrosis, pulmonary HTN, pleurisy, pleural effusions
Cardiac	Left ventricular dysfunction, pericarditis, pericardial effusion, arrhythmias
Musculoskeletal	Polyarthralgias "Resorption of distal tufts" (radiological finding) Proximal weakness 2° to disuse, atrophy, low grade myopathy, tendon friction rubs
Endocrine	Hypothyroidism

Features of Pathologic Raynaud's Syndrome
- New onset
- Asymmetric
- Precipitated by stimuli other than cold or emotion
- Associated with distal pulp pitting or tissue reabsorption
- Digit ischemia
- Capillary dilatation by capillaroscopy

Investigations
- blood work
  - CBC, Cr, ANA
  - anti-topoisomerase 1/anti-Scl-70 antibody: specific but not sensitive for diffuse systemic sclerosis
  - anti-centromere antibody: favours diagnosis of CREST (limited systemic sclerosis)
  - anti-RNA polymerase III antibody: associated with severe skin involvement, increased risk of renal crisis
- PFT
  - assess and monitor for ILD
- echocardiogram
  - rule out pulmonary HTN
- imaging
  - baseline CXR to rule out ILD

Treatment
- dermatologic
  - good skin hygiene
  - low-dose prednisone (>20 mg may provoke renal crisis if susceptible), MTX (limited evidence)
- vascular
  - Raynaud's: keep hands and body warm, smoking cessation
  - vasodilators (CCBs, local nitroglycerine cream, systemic PGE2 inhibitors, PDE5 inhibitors), fluoxetine
- gastrointestinal
  - GERD: PPIs are first-line, then H2-receptor agonists
  - small bowel bacterial overgrowth: broad spectrum antibiotics (tetracycline, metronidazole)
  - motility disturbances: prokinetics
- renal disease
  - ACE inhibitor for hypertensive crisis
  - see Nephrology, NP36 for scleroderma renal crisis
- pulmonary
  - early interstitial disease: mycophenolate mofetil (less toxicity) or cyclophosphamide
  - pulmonary HTN: vasodilators (e.g. bosentan, epoprostenol, and PDE5 inhibitors)
  - rapidly progressive disease at risk of organ failure: consider hematopoietic stem cell transplantation
- cardiac
  - pericarditis: systemic steroids
- musculoskeletal
  - arthritis: NSAIDs
  - myositis: systemic steroids

Inflammatory Myopathy

Definition
- autoimmune diseases characterized by proximal muscle weakness ± pain
- muscle becomes damaged by a non-suppurative lymphocytic inflammatory process
- associated with malignancy
  - increased risk of malignancy: age >50, DMM > PM, elevated CK, peak incidence of malignancy at onset of myositis or within 1st yr, dysphagia, ulcerative skin lesions, cutaneous vasculitis, anti-P155/140 antibody
- associated with other connective tissue diseases, Raynaud's phenomenon, autoimmune disorders

Classification
- PM/DMM
- adult and juvenile forms
- newly characterized entities:
  - focal necrotizing myopathy (secondary to statin)
  - amyopathic myopathy (anti-synthetase syndrome, MDA-5 syndrome)

Inclusion Body Myositis
- age >50, M>F, slowly progressive, vacuoles in cells on biopsy
- patient unresponsive to treatment
- distal and proximal muscle weakness
- muscle biopsy positive for inclusion bodies

POLYMYOSITIS/DERMATOMYOSITIS

Definition
- PM and DMM are idiopathic inflammatory myopathies characterized by inflammation and proximal skeletal muscle weakness
- notably, DMM often presents with characteristic skin manifestations

Signs of DMM
Gottron's papules and Gottron's sign are pathognomonic of DMM (occur in 70% of patients)

Etiology and Pathophysiology
- PM is a T cell-mediated process with myocytes being the primary target, characterized by focal endomysial infiltrates (CD8+ T cells) surrounding muscle fibres, found in adults
- DMM is a complement mediated process with perivascular inflammatory infiltrates (CD4+ T cells > CD8+ T cells) leading to perifascicular atrophy of muscle fibres

Malignancies Associated with DMM
- Breast
- Lung
- Colon
- Ovarian

Signs and Symptoms
- progressive symmetrical proximal muscle weakness (shoulder and hip) developing over wk to mo; difficulty lifting head off pillow, arising from chair, climbing stairs
- dermatological
  - DMM has characteristic dermatological features (F>M, children and adults)
    - Gottron's papules
      - pink-violaceous, flat-topped papules overlying the dorsal surface of the MCP and IP
    - Gottron's sign
      - erythematous, smooth or scaly patches over the extensor surface of elbows, knees, or medial malleoli
    - heliotrope rash: violaceous rash over the eyelids; usually with edema
    - shawl sign: poikilodermatous, erythematous rash over neck, upper chest, and shoulders
    - mechanic's hands: dry, crackled lesions on palmar and lateral surfaces of digits, especially over the pulp space, also seen in a subtype of myositis called anti-synthetase syndrome
    - periungual erythema
- cardiac
  - arrhythmias, congestive heart failure, conduction defect, ventricular hypertrophy, pericarditis
- gastrointestinal
  - oropharyngeal and lower esophageal dysphagia, reflux
- pulmonary
  - weakness of respiratory muscles, ILD, aspiration pneumonia

Investigations
- general lab tests: CK, CBC, ESR and/or CRP, TSH
- serologic tests: ANA, anti-Jo-1 (DMM), anti-Mi-2, anti-SRP (usually not available at commercial labs)
- imaging: MRI may be used to localize biopsy site
- EMG: characteristic findings of muscle inflammation and damage
- muscle biopsy can aid in diagnosis, however not needed in those with classic skin findings and muscle weakness

Treatment
- non-pharmacological treatment
  - PT and OT, speech-language therapy for esophageal dysfunction
- pharmacological treatment
  - high-dose glucocorticoid (e.g. prednisone 1 mg/kg/d) usually not exceeding 80 mg daily and slow taper after patient improvement (~6 wk)
  - add immunosuppressive agents (azathioprine, MTX)
  - IVIG if severe or refractory
  - hydroxychloroquine for DMM rash
- malignancy surveillance
  - detailed history and physical (breast, pelvic, and rectal exams)
  - CXR, abdominal and pelvic U/S, fecal occult blood, Pap test, mammogram ± CT scan (thoracic, abdominal, pelvic)

Sjögren's Syndrome

Definition
- autoimmune condition characterized by dry eyes (keratoconjunctivitis sicca/xerophthalmia) and dry mouth (xerostomia), caused by lymphocytic infiltration of salivary and lacrimal glands
- exists on a spectrum and may evolve into a systemic disorder (20%) with diminished exocrine gland activity and extraglandular features
- primary and secondary forms (associated with RA, SLE, DMM, and HIV)
- prevalence 0.5%, F>>M at 10:1, 40-60 yr
- increased risk of non-Hodgkin's lymphoma (lifetime incidence 6-7%)

Table 19. The American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) Classification Criteria for Primary Sjögren's Syndrome (at least one inclusion criteria, no condition in exclusion criteria, score ≥4)

Criteria	Score	Comments
Labial salivary gland biopsy with focal lymphocytic sialadenitis with focus score ≥1 focus /4mm^2	3	Focus scores are histopathologic grading systems Strongly associated with phenotypic ocular and serological components of Sjögren's
Anti-SSA- or Ro-positive	3	
Ocular staining score ≥5 (or van Bijsterfeld score ≥4 on at least one eye)	1	Ocular staining score based on fluorescein dye examination of conjunctiva and cornea to determine clinical changes
Schirmer's test ≤5 mm/5 min on at least one eye	1	
Unstimulated whole saliva flow rate ≤0.1 mL/min	1	
Inclusion criteria (positive response to at least one question): 1) Have you had daily, persistent, troublesome dry eyes for more than 3 mo? 2) Do you have a recurrent sensation of sand or gravel in the eyes? 3) Do you use tear substitutes more than 3 times a d? 4) Have you had a daily feeling of dry mouth for more than 3 mo? 5) Do you frequently drink liquids to aid in swallowing dry food?		
Exclusion criteria include prior diagnosis of any of the following conditions: 1) History of head and neck radiation treatment, 2) Active hepatitis C infection (with confirmation by polymerase chain reaction, 3) AIDS, 4) Sarcoidosis, 5) Amyloidosis, 6) Graft-versus-host disease, 7) IgG4-related disease		

Arthritis Rheumatol. 2017;69:35-45

Signs and Symptoms
- "sicca complex": dry eyes (keratoconjunctivitis sicca/xerophthalmia), dry mouth (xerostomia), complicated by staphylococcal blepharitis
- dental caries, oral candidiasis, angular cheilitis (inflammation and fissuring at the labial commissures of the mouth)
- extra-glandular manifestations
  - fatigue, low-grade fever
  - autoimmune thyroid dysfunction
  - arthralgias, arthritis
  - subclinical diffuse ILD, xerotrachea leading to chronic dry cough
  - renal disease, glomerulonephritis
  - palpable purpura, vasculitis
  - peripheral neuropathy
  - lymphoma risk greatly increased

Classic Triad (identifies 93% of Sjögren's patients)
- Dry eyes
- Dry mouth (xerostomia) → dysphagia
- Arthritis (small joint, asymmetrical, non-erosive) but may be associated with rheumatoid arthritis, in which case, the arthritis is erosive and symmetric

Treatment
- ocular
  - artificial tears/tear gel if severe, moisture retaining eyewear, humidifiers, or surgical punctal occlusion for dry eyes
- oral
  - good dental hygiene, hydration
  - avoid alcohol and tobacco
  - parasympathomimetic agents that stimulate salivary flow (e.g. pilocarpine)
  - topical nystatin or clotrimazole x 4-6 wk for oral candidiasis
- systemic treatments (e.g. hydroxychloroquine, corticosteroids) are ineffective, rituximab can be used in severe organ-threatening disease (e.g. vasculitis)

Mixed Connective Tissue Disease

- syndrome with features of 3 different connective tissue diseases (e.g. SLE, scleroderma, myositis)
- common symptoms: Raynaud's phenomenon, swollen fingers
- blood work: anti-RNP (see Table 10, RH7)
- treatment is generally guided by the severity of symptoms and organ system involvement
- prognosis
  - prognosis is variable: some individuals go into remission, others develop a distinct connective tissue disease (e.g. SLE, SSc), and others develop a severe disease course
  - pulmonary arterial HTN is a major cause of death

Overlap Syndrome

- syndrome with sufficient diagnostic features of 2+ different CTDs

Vasculitides

- inflammation and subsequent necrosis of blood vessels leading to tissue ischemia or infarction of any organ system
- diagnosis
  - clinical suspicion: suspect in cases of unexplained multiple organ ischemia or systemic illness with no evidence of malignancy or infection; constitutional symptoms such as fever, weight loss, anorexia, fatigue
  - labs non-specific: anemia, increased WBC and CRP, abnormal U/A
  - investigations: biopsy if tissue accessible; angiography if tissue inaccessible
- treatment generally involves corticosteroids and/or immunosuppressive agents

Table 20. Classification of Vasculitis and Characteristic Features

Classification	Characteristic Features
SMALL VESSEL	
Non-ANCA-associated	Immune complex-mediated (most common mechanism)
Anti-GBM (Goodpasture's disease)	Autoantibodies targeting type IV collagen in both glomerular basement membrane and alveoli causing glomerulonephritis and/or pulmonary findings
Anti-C1q vasculitis (hypocomplementemic urticarial vasculitis syndrome)	Specific autoimmune disorder with at least 6 mo of urticaria with C1q complement deficiency with various systemic findings
Predominantly cutaneous vasculitis	Also known as hypersensitivity/leukocytoclastic vasculitis
IgA vasculitis (formerly Henoch-Schönlein purpura (HSP)) (see Paediatrics, P98)	Vascular deposition of IgA causing systemic vasculitis (skin, GI, renal), usually self-limiting; most common in childhood
Cryoglobulinemic vasculitis (CV)	Systemic vasculitis caused by circulating cryoproteins forming immune complexes; 60-80% of cases are due to hepatitis C, 5-10% are due to a CTD (SLE, RA, SS), 5-10% are due to a lymphoproliferative disorder, and the remaining 5-10% are idiopathic or "essential." CV may be associated with underlying infection (e.g. hepatitis C) or connective tissue disease
ANCA-associated (i.e. PR3-ANCA) Granulomatosis with polyangiitis (GPA, formerly Wegener's) PR3 (c-ANCA) > MPO (p-ANCA)	Granulomatous inflammation of vessels of respiratory tract and kidneys leading to pulmonary hemorrhage and glomerulonephritis; initially may have upper respiratory tract infection (URTI) symptoms (sinusitis); most common in middle age
EGPA, formerly Churg-Strauss syndrome (50% ANCA positive)	Granulomatous inflammation of vessels with hypereosinophilia and eosinophilic tissue infiltration, frequent lung involvement (asthma, allergic rhinitis), associated with MPO-ANCA in 40-50% of cases. Other manifestations include peripheral neuropathy (70%), GI involvement, myocarditis, and rarely coronary arteritis; average age 40s
Microangiopathic polyangiitis (MPA) (70% ANCA positive, usually MPO)	Pauci-immune necrotizing vasculitis, affects kidneys (necrotizing glomerulonephritis), lungs (capillaritis and alveolar hemorrhage), and skin; most common in older age
MEDIUM VESSEL	
PAN	Segmental, non-granulomatous necrotizing inflammation Unknown etiology in most cases, any age (average 40-50s), M>F
Kawasaki disease (see Paediatrics, P98)	Arteritis and mucocutaneous lymph node syndrome
LARGE VESSEL	
GCA/Temporal arteritis	Inflammation predominantly of the aorta and its branches Ages >50, F>M Temporal headache, jaw claudication, scalp tenderness, vision loss
Takayasu's	"Pulseless disease," unequal peripheral pulses, chronic inflammation, most often the aorta and its branches Most common in young adults of Asian descent, ages 10-40, F>M, risk of aortic aneurysm

Features of Small Vessel Vasculitis
- Palpable purpura
- Vesicles
- Chronic urticaria
- Superficial ulcers (erosions)

- **c-ANCA** (i.e. pR3-ANCA): cytoplasmic anti-neutrophil cytoplasmic Ab associated with anti-PR3
- **p-ANCA** (i.e. MPO-ANCA): perinuclear anti-neutrophil cytoplasmic Ab associated with multiple antigens, e.g. myeloperoxidase, lactoferrin (IBD), cathepsin, elastase, etc. Of these, only antibodies to myeloperoxidase have been associated with the development of vasculitis

EGPA Triad
- Allergic rhinitis and asthma (often quiescent at time of vasculitis)
- Eosinophilic infiltrative disease resembling pneumonia
- Systemic vasculitis often mononeuritis multiplex/peripheral neuropathy and peripheral eosinophilia

Features of Medium Vessel Vasculitis
- Livedo reticularis
- Erythema nodosum
- Raynaud's phenomenon
- Nodules
- Digital infarcts
- Ulcers

Table 20. Classification of Vasculitis and Characteristic Features

Classification	Characteristic Features
OTHER VASCULITIDES	
Buerger's disease ("Thromboangiitis Obliterans")	Inflammation and clotting of small and medium-sized arteries and veins of distal extremities, may lead to distal claudication and gangrene, the most important etiologic factor is cigarette smoking. Most common in young Asian males, M>F
Behçet's disease	Multi-system disorder presenting with ocular involvement (uveitis), recurrent oral and genital ulceration, venous thrombosis, skin and joint involvement Most common in Mediterranean and Asian populations, average age 30 y/o, M>F
Vasculitis mimicry (i.e. pseudovasculitis)	Cholesterol emboli, atrial myxoma, subacute bacterial endocarditis (SBE), APS

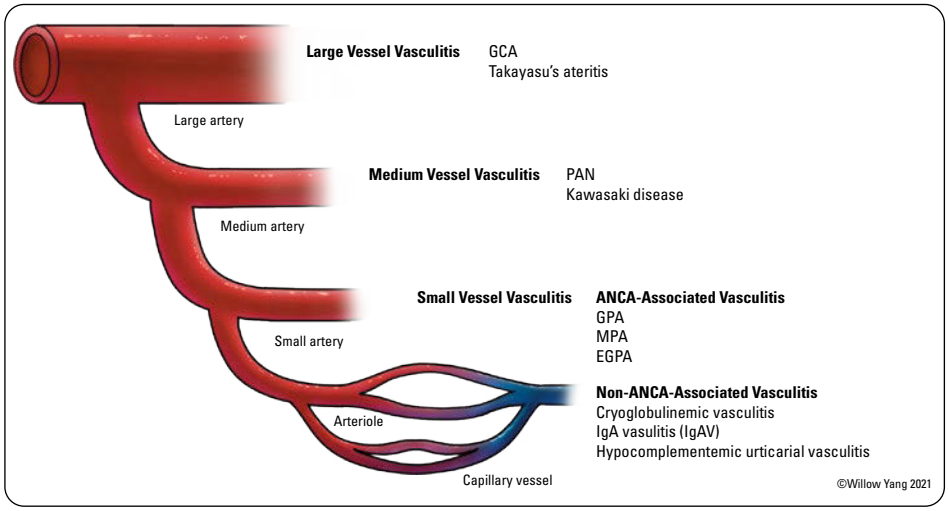

Figure 9. Classification of vasculitides by vessel size
J. C. Jennette, R. J. Falk, P. A. Bacon, et al, Arthritis & Rheumatology (65, 1), p. 1, copyright © 2020, Modified by Permission of John Wiley and Sons

Small Vessel Non-ANCA-Associated Vasculitis

CUTANEOUS VASCULITIS

- subdivided into:
  - drug-induced vasculitis
  - serum sickness reaction
  - vasculitis associated with other underlying primary diseases (CTD, infections, malignancies – hematologic > solid tumours)

Etiology and Pathophysiology

- cutaneous vasculitis following:
  - drug exposure (allopurinol, gold, sulfonamides, penicillin, phenytoin)
  - viral or bacterial infection
  - idiopathic causes
- small vessels involved (post-capillary venules most frequently)
- usually causes a leukocytoclastic vasculitis: debris from neutrophils around vessels
- sometimes due to cryoglobulins which precipitate in cold temperatures

Signs and Symptoms

- palpable purpura (usually on lower extremities) ± vesicles and ulceration, urticaria, macules, papules, bullae, subcutaneous nodules
  - renal or joint involvement may occur, especially in children

Investigations

- vascular involvement (both arteriole and venule) established by skin biopsy

Treatment

- stop possible offending drug; treatment of underlying primary disease
- NSAID, low-dose corticosteroids
  - immunosuppressive agents in resistant cases
- usually self-limiting

Small Vessel ANCA-Associated Vasculitis

GRANULOMATOSIS WITH POLYANGIITIS (GPA, formerly known as Wegener's Granulomatosis)

Definition
- granulomatous inflammation of vessels that may affect the upper airways (rhinitis, sinusitis), lungs (pulmonary nodules, infiltrates caused by pulmonary hemorrhage), and kidneys (glomerulonephritis, renal failure)
- highly associated with c-ANCA by indirect immunofluorescence (IIF) and PR3-ANCA by ELISA; however, changes in ANCA levels do not predict remission or relapse
- incidence 2-3 in 100000; more common in Northern latitudes

Table 21. Classification Criteria for GPA*

Criteria	Description
1. Nasal or oral involvement	Inflammation, ulcers, epistaxis
2. Abnormal findings on CXR	Nodules, cavitations, or fixed infiltrates
3. Urinary sediment	Microscopic hematuria ± RBC casts
4. Biopsy of involved tissue	Lungs show granulomas, kidneys show necrotizing segmental glomerulonephritis, skin shows vasculitis

*Diagnosed if 2 or more of the above 4 criteria present
American College of Rheumatology, 1990

Etiology and Pathophysiology
- pathogenesis depends on genetic susceptibility and environmental triggers (e.g. infection)
  - dysregulated immune response due to loss of B and T cell tolerance
  - acute vascular injury mediated by neutrophils and monocytes

Signs and Symptoms
- systemic
  - malaise, fever, weakness, weight loss
- head, eyes, ears, nose, and throat (HEENT)
  - sinusitis or rhinitis, nasal crusting and bloody nasal discharge, nasoseptal perforation, saddle nose deformity
  - proptosis due to: inflammation/vasculitis involving extraocular muscles, granulomatous retrobulbar space-occupying lesions or direct extension of masses from the upper respiratory tract
  - hearing loss due to involvement of cranial nerve (CN) VIII
- pulmonary
  - cough, hemoptysis, granulomatous upper respiratory tract masses, tracheal and bronchial stenosis
- renal
  - hematuria, proteinuria, elevated creatinine, glomerulonephritis
- other
  - joint, skin, eye complaints-iritis, vasculitic neuropathy

Investigations
- blood work: anemia (normal mean corpuscular volume (MCV)), increased WBC, increased Cr, increased CRP, elevated platelet count, ANCA (PR3 > MPO)
- urinalysis: proteinuria, hematuria, RBC casts
- CXR/CT: pneumonitis, lung nodules, infiltrations, cavitary lesions
- biopsy for confirmation of disease: skin, renal (segmental necrotizing glomerulonephritis), lung (vasculitis, necrosis)
- CRP may be used to monitor response to treatment in some patients

Treatment
- severe, life or organ-threatening disease
  - induction therapy: IV glucocorticoids + either IV or oral cyclophosphamide OR rituximab
  - glucocorticoid: methylprednisolone 0.5-1.0 g/d IV x1-3 d followed by prednisone 1 mg/kg/d PO x2-4 wk and then gradual taper
  - cyclophosphamide: 2 mg/kg/d (max 200 mg/d) PO for maximum of 3-6 mo OR 15 mg/kg IV (max 1200 mg) every 2 wk for 3 doses, then every 3 wk for 3-6 doses (dose adjust for older age and renal failure)
  - rituximab: 375 mg/m² x4 weekly infusions
  - maintenance therapy: initiated once remission is achieved, consider corticosteroid-sparing agents such as rituximab for maintenance, azathioprine, MTX, and mycophenolate are reasonable alternatives

Classic Features of GPA
- Necrotizing granulomatous vasculitis of lower and upper respiratory tract
- Focal segmental glomerulonephritis

Efficacy of Remission Induction Regimens for ANCA-Associated Vasculitides (RAVE) Trial
NEJM 2013;369:417-427
Study: Multicentre, randomized, double-blind, double-dummy, non-inferiority trial.
Intervention: Rituximab
Outcome: Complete remission of disease by 6 mo, with remission maintained through 18 mo.
Results: 64% of the patients in the rituximab group, as compared with 53% of the patients in the cyclophosphamide–azathioprine group, had a complete remission by 6 mo. At 12 and 18 mo, 48% and 39%, respectively, of the patients in the rituximab group maintained complete remission, as compared with 39% and 33%, respectively, in the comparison group. Rituximab met the prespecified criteria for noninferiority. There was no significant difference between the groups in any efficacy measure, including the duration of complete remission and the frequency or severity of relapses. Among the 101 patients who had relapsing disease at baseline, rituximab was superior to conventional immunosuppression at 6 mo (P=0.01) and at 12 mo (P=0.009) but not at 18 mo.
Conclusion: In patients with severe ANCA-associated vasculitis, a single course of rituximab was as effective as continuous conventional immunosuppressive therapy for the induction and maintenance of remission over the course of 18 mo.

Long-Term Rituximab Use to Maintain Remission of Antineutrophil Cytoplasmic Antibody-Associated Vasculitis: A Randomized Trial
Ann Intern Med 2020;173:179-87
Purpose: To assess the efficacy of prolonged rituximab therapy in reducing AAV relapses in patients in complete remission following an initial phase of maintenance therapy.
Methods: 68 patients were randomized to receive an infusion of rituximab or placebo every 6 mo for 18 mo.
Results: At 28 mo, estimates of relapse-free survival were 96% and 74% in the rituximab and placebo groups, respectively, representing an absolute difference of 22% (CI, 9-36%) and a hazard ratio of 7.5 (CI, 1.67-33.7) (P=0.008).
Conclusion: Prolonged rituximab therapy resulted in lower rates of AAV relapse than standard maintenance therapy.

- plasma exchange can be an adjunct treatment for patients with severe organ involvement (renal failure, pulmonary hemorrhage) not responding to conventional induction treatment
- non-organ-threatening disease
  - prednisone 0.5-1 mg/kg/d PO and MTX 15-25 mg PO/SC weekly OR azathioprine 2 mg/kg/d
- screening and prophylaxis
  - all patients should receive screening and prophylaxis for corticosteroid-induced osteoporosis, PUD prevention, and *Pneumocystis jiroveci* prophylaxis (trimethoprim/sulfamethoxazole 160/800 mg PO 3x/wk)

Medium Vessel Vasculitis

PAN

Definition
- systemic, necrotizing vasculitis of medium-sized vessels, defined as visceral arteries and their branches
- ANCA-negative, classically lung-sparing
- 5-10% associated with hepatitis B positivity
- incidence 0.7 in 100000; affects individuals between 40-60 yr; M:F=2:1

Table 22. Classification Criteria for PAN*

Criteria	Description
1. Weight loss	≥4 kg, not due to dieting or other factors
2. Myalgias, weakness, or leg tenderness	Diffuse myalgias or muscle weakness
3. Livedo reticularis	Mottled, reticular pattern over skin
4. Neuropathy	Mononeuropathy, mononeuropathy multiplex, or polyneuropathy
5. Testicular pain or tenderness	Not due to infection, trauma, or other causes
6. dBP >90 mmHg	Development of HTN with dBP >90 mmHg
7. Elevated Cr or BUN	Cr >130 µmol/L (1.5 mg/dL), BUN >14.3 mmol/L (40 mg/dL)
8. Hepatitis B positive	Presence of hepatitis B surface antigen or Ab
9. Arteriographic abnormality	Commonly aneurysms
10. Biopsy of artery	Presence of granulocytes and/or mononuclear leukocytes in the artery wall

*Diagnosed if 3 or more of the above 10 criteria present
American College of Rheumatology, 1990

Etiology and Pathophysiology
- focal pan-mural necrotizing vasculitis in small and medium-sized arteries
- thrombosis, aneurysm, or dilatation at lesion site may occur
- healed lesions show proliferation of fibrous tissue and endothelial cells that may lead to luminal occlusion

Signs and Symptoms
- systemic: fatigue, weight loss, weakness, fever, arthralgias
- dermatologic: livedo reticularis, nodules, purpura, eruptions
- renal: renal insufficiency leading to HTN
- neurologic: mononeuropathy multiplex in both motor and sensory nerves
- abdominal: abdominal pain, mesenteric arteritis

Investigations
- blood work: CBC, CRP, Cr, BUN, urinalysis, liver enzymes, p-ANCA, hepatitis B and C serology
- imaging: CT or MRI angiography shows beading appearance of blood vessels seen
- biopsy of affected organ (e.g. skin, nerve); biopsy of highly vascular tissues (e.g. liver) not recommended due to risk of aneurysm rupture

Treatment
- PAN with no major organ manifestations
  - glucocorticoids ± azathioprine
- PAN with major organ manifestations (CNS, cardiac, GI, renal)
  - induction therapy with high-dose glucocorticoids + cyclophosphamide for 3-6 mo followed by maintenance therapy with low-dose prednisone and either azathioprine, MTX, or leflunomide
  - treatment should be a minimum of 18 mo
- hepatitis B virus-associated vasculitis
  - prednisone 1 mg/kg/d PO x7 d (then taper and withdraw by 14 d) ± methylprednisolone 15 mg/kg/d IV x1-3 d
  - after corticosteroid therapy, treat with plasma exchange + antiviral therapy

Large Vessel Vasculitis

GIANT CELL ARTERITIS/TEMPORAL ARTERITIS

Table 23. Classification Criteria for GCA*

Criteria	Description
1. Age at onset ≥50	
2. New H/A	Often temporal
3. Temporal artery abnormality	Temporal artery tenderness or decreased pulsations, not due to arteriosclerosis
4. Elevated ESR	ESR ≥50 mm/h
5. Abnormal artery biopsy	Mononuclear cell infiltration or granulomatous inflammation, usually with multinucleated giant cells

*Diagnosed if 3 or more of the above 5 criteria present
American College of Rheumatology, 1990

GCA Criteria
Presence of 3 or more criteria yields sensitivity of 94%, specificity of 91%

Epidemiology
- most common vasculitis in North America
- patients >50 yr; peak incidence 70-80 yr
- F:M=2:1
- north-south gradient (predominance in Northern Europe and US)
- affects extracranial arteries

Signs and Symptoms
- new onset temporal H/A ± scalp tenderness overlying temporal artery
- sudden, painless loss of vision and/or diplopia due to narrowing of the ophthalmic or posterior ciliary arteries (PCA more common); can affect both eyes
- tongue and jaw claudication (pain in muscles of mastication on prolonged chewing)
- PMR (proximal pain and stiffness, constitutional symptoms, elevated ESR) occurs in 30% of patients
- aortic arch syndrome (involvement of subclavian and brachial branches of aorta resulting in pulseless disease), aortic aneurysm ± rupture are late complications
- constitutional symptoms (e.g. fever of unknown origin in patients ≥65 yr) and shoulder/pelvic girdle pain and stiffness

Medical Emergency
If untreated, GCA can lead to permanent blindness in 20-25% of patients
Treat on clinical suspicion

Investigations
- diagnosis made by clinical suspicion, increased ESR, increased CRP, colour Doppler U/S of temporal ± axillary arteries (+ halo sign), MRI, consider temporal artery biopsy

Treatment
- if suspect GCA, immediately start high-dose prednisone 1 mg/kg PO in divided doses for 2-4 wk, and then taper prednisone by 10 mg per 1-2 wk as symptoms resolve; highly effective in treatment and prevention of blindness and other vascular complications
- consider low-dose ASA to help decrease visual loss
- if presenting with vision loss at diagnosis, methylprednisolone 1000 mg/d IV for 3 d followed by high-dose prednisone 1 mg/kg/d PO in divided doses for 4 wk
- tocilizumab, an IL-6 receptor monoclonal antibody, has also been used in combination with glucocorticoids to treat GCA (new or relapsing)

Prognosis
- increased risk of thoracic aortic aneurysm and aortic dissection
- yearly CXR ± abdominal U/S as screening

Seronegative Rheumatic Disease

Table 24. A Comparison of the Spondyloarthropathies

Feature	AS	PsA	ReA	EA
M:F	3:1	1:1	8:1	1:1
Age of Onset	20s	35-45	20s	Any
Peripheral Arthritis	25%	96%	90%	Common
Distribution	Axial, large joints	Any	LE*	LE*
Sacroiliitis	100%	40%	80%	20%
Dactylitis	Uncommon	Common	Occasional	Uncommon
Enthesitis	Common	Common	Common	Less Common
Skin Lesions	Rare	100% Eventually psoriasis, 70% at onset of arthritis	Occasional Keratoderma blennorrhagica	Occasional Pyoderma, erythema nodosum
Uveitis	Common	Occasional	20%	Rare
Urethritis	Rare	Uncommon	Common	Rare
HLA-B27	90-95%	40%	80%	30%

*LE = lower extremities

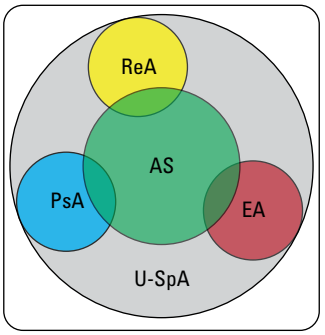

Figure 10. Spondyloarthropathy subsets

AS shares some features with the other three types of seronegative spondyloarthropathies such as ReA, EA, PsA, and U-sPA

Ankylosing Spondylitis

Definition

- chronic inflammatory arthritis involving the sacroiliac joints and vertebrae
- enthesitis is a major feature (e.g. Achilles tendinitis, plantar fasciitis)
- prototypical spondyloarthropathy

Table 25. ASAS Classification Criteria for Axial Spondyloarthritis*

1. Back pain of any type for at least 3 mo and age of onset <45 yr
2. Sacroiliitis on imaging plus ≥1 AS feature or HLA-B27 positive plus ≥2 AS features

AS Features	Sacroiliitis on Imaging
HLA-B27 positive	Active (acute) inflammation on MRI highly suggestive of sacroiliitis associated with AS
Inflammatory back pain	OR
Arthritis	Definite radiographic sacroiliitis ≥grade 2 bilaterally or grade 3-4 unilaterally
Enthesitis (heel)	
Uveitis	
Dactylitis	
Psoriasis	
Crohn's disease/colitis	
Good response to NSAIDs	
FMHx of SpA	
Elevated CRP	

*Spondylarthropathy: inflammatory joint disease of the vertebral column

Etiology and Pathophysiology

- inflammation → osteopenia → erosion → ossification → osteoproliferation (syndesmophytes)

Epidemiology

- M:F=3:1; females have milder disease (may be under-diagnosed), more peripheral arthritis, and upper spine spondylitis
- 90-95% of patients are HLA-B27 positive (9% of the general population is HLA-B27 positive)

Consider AS in the differential for causes of aortic regurgitation

Rule of 2s
AS occurs in
0.**2**% of the general population
2% of HLA-B27 positive individuals
20% of HLA-B27 positive individuals with affected family member

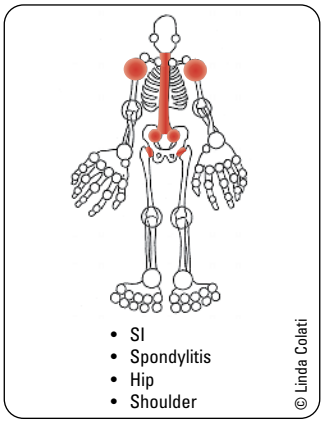

Figure 11. Common sites of involvement of AS

The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI)
Self-reported scoring system that focuses on fatigue, axial pain, peripheral pain, enthesitis, and morning stiffness

Table 26. Types of Back Pain

Parameter	Mechanical	Inflammatory
Past History	±	++
Family History	–	+
Onset	Acute	Insidious
Age	15-90 yr	<45 yr
Sleep Disturbance	±	++ (worse during 2nd half of night)
Morning Stiffness	<30 min	>1 h
Involvement of Other Systems	–	+
Exercise	Worse	Better
Rest	Better	Worse
Radiation of Pain	Anatomic (L5-S1)	Diffuse (thoracic, buttock)
Sensory Symptoms	+	–
Motor Symptoms	+	–

Signs and Symptoms

- **axial**
  - mid and lower back stiffness, morning stiffness >1 h, night pain, alternating buttock pain, painful SI joint (+ FABER test)
  - spinal restriction (decreased ROM): lumbar (decreased Schöber), thoracic (decreased chest wall expansion, normal >5 cm at T4), cervical (global decrease, often extension first)
  - postural changes: decreased lumbar lordosis + increased thoracic kyphosis + increased cervical flexion = increased occiput to wall distance (>5 cm)
- **peripheral**
  - asymmetrical large joint arthritis, most often involving lower limb
  - enthesitis: tenderness over tibial tuberosity, or Achilles tendon and plantar fascia insertions into the calcaneus
  - dactylitis: toes or fingers
- **extra-articular manifestations**
  - ophthalmic: acute anterior uveitis is common (25-30% patients)
  - renal: amyloidosis (late and rare), IgA nephropathy
  - gastrointestinal: IBD
  - cardiac: aortitis, aortic regurgitation, pericarditis, conduction disturbances, heart failure (rare)
  - respiratory: apical fibrosis (rare)
  - neurologic: cauda equina syndrome (rare)
  - skin: psoriasis

Investigations

- x-ray of SI joint: "pseudowidening" of joint due to erosion with joint sclerosis ➔ bony fusion (late), symmetric sacroiliitis
- x-ray of spine: "squaring of edges" from erosion and sclerosis on corners of vertebral bodies (shiny corner sign) leading to ossification of outer fibres of annulus fibrosis (bridging syndesmophytes) ➔ "bamboo spine" radiographically
- MRI of spine: assess activity in early disease; detection of cartilage changes, bone marrow edema, bone erosions, and subchondral bone changes. Best seen on T2 short tau inversion recovery (STIR) images (suppress fat and see bone edema)
- labs: CBC, elevated ESR/CRP, ALP, Ca^{2+}, serum protein electrophoresis (SPEP), BMD, HLA-B27

Treatment

- non-pharmacological therapy
  - prevent fusion from poor posture and disability through: exercise (e.g. swimming), postural and deep breathing exercises, outpatient PT, and smoking cessation
- pharmacological therapy
  - NSAIDs (first line of treatment for peripheral and axial disease)
  - glucocorticoids (topical eye drops, local injections, occasionally require systemic steroids prior to other effective Rx)
  - DMARDs only for peripheral arthritis (SSZ, MTX)
  - if inadequate response to two NSAIDs (or DMARD for peripheral arthritis only), consider anti-TNF agents or anti-IL-17 for axial and peripheral involvement
  - manage extra-articular manifestations
- surgical therapy
  - hip replacement and vertebral osteotomy for marked deformity (latter rarely performed)

Prognosis

- spontaneous remissions and relapses are common and can occur at any age
- function may be excellent despite spinal deformity
- favourable prognosis if female and age of onset >40 yr
- early onset with hip disease may lead to severe disability; may require arthroplasty

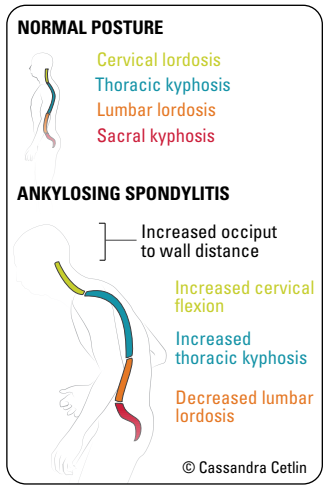

Figure 12. AS postural change

FABER (Flexion, ABduction, and External Rotation) Test
Passively flex, abduct, then gently externally rotate the leg. If pain is elicited during this movement, the location of the pain may help determine the location of the patient's pathology (e.g. hip joint, SI joint). However, it is poorly reproducible and inaccurate in discerning inflammatory vs. mechanical back pain

Modified Schöber Test

- Patient must be standing erect with normal posture
- Mark an imaginary line connecting both posterior superior iliac spines (close to the dimples of Venus)
- The next mark is placed 10 cm above
- The patient bends forward maximally: measure the difference
- Report the increase (in cm to the nearest 0.1 cm)
- The better of two tries is recorded

Extra-Articular Manifestations of AS

6 As
Atlanto-axial subluxation
Anterior uveitis
Apical lung fibrosis
Aortic incompetence
Amyloidosis (kidneys)
Autoimmune bowel disease (ulcerative colitis)

Enteropathic Arthritis

- see Gastroenterology, *Inflammatory Bowel Disease*, G22
- MSK manifestations in the setting of either ulcerative colitis (UC) or Crohn's disease (CD) include peripheral arthritis (large joint, asymmetrical), spondylitis, and hypertrophic osteoarthropathy
- non-arthritic MSK manifestations can occur secondary to steroid treatment of bowel inflammation (arthralgia, myalgia, osteoporosis, AVN)

Both AS and EA feature symmetric sacroiliitis

Table 27. Comparing Features of Spondylitis vs. Peripheral Arthritis in EA

Parameter	Spondylitis	Peripheral Arthritis
HLA-B27 Association	Yes	No
Gender	M>F	M=F
Onset Before IBD	Yes	No
Parallels IBD Course	No	Yes
Type of IBD	UC=CD	CD
Treatment	NSAIDs (use cautiously, may exacerbate bowel disease); TNF inhibitors if resistant	NSAIDs, DMARDs; TNF inhibitors if resistant

Psoriatic Arthritis

Definition

- arthritic inflammation associated with psoriasis

Etiology and Pathophysiology

- unclear but many genetic, immunologic, and some environmental factors involved (e.g. bacterial, viral, and trauma)

Check "hidden" areas for psoriatic lesions (ears, hairline, umbilicus, gluteal cleft, nails)
TNF-α inhibitors are effective treatments for PsA with no important added risks associated with their short-term use

Epidemiology

- psoriasis affects 1% of the population
- arthropathy in 15% of patients with psoriasis
- 15-20% of patients will develop joint disease before skin lesions appear

Signs and Symptoms

- **dermatologic**
  - well-demarcated erythematous plaques with silvery scale
  - nail involvement: pitting, transverse or longitudinal ridging, discolouration, subungual hyperkeratosis, onycholysis, and oil drops
- **musculoskeletal**
  - 5 general patterns
    - asymmetric oligoarthritis (<5 small and/or large joints affected in asymmetric distribution; most common – 70%)
    - arthritis of DIPs with nail changes
    - symmetric polyarthritis (similar to RA)
    - sacroiliitis and spondylitis (usually older, male patients)
    - arthritis mutilans (destructive and deforming small joint polyarthritis
  - other findings: dactylitis, enthesopathy, morning stiffness >30 min (50%)
- **ophthalmic**
  - conjunctivitis, iritis (anterior uveitis)
- **cardiac and respiratory** (late findings)
  - aortic insufficiency
  - apical lung fibrosis
- **neurologic**
  - cauda equina syndrome
- **radiologic**
  - floating syndesmophytes
  - pencil-in-cup appearance at IPs
  - osteolysis, periostitis

Treatment

- treat skin lesions (e.g. steroid cream, salicylic and/or retinoic acid, tar, UV light)
- NSAIDs and/or IA steroids (as an adjuvant), benefit should be seen within a few wk, should not be the sole therapy >3 mo
- DMARDs to minimize erosive disease (use early in peripheral joint involvement)
  - non-biologic DMARDs (MTX, SSZ, or leflunomide)
  - biologic therapies include anti-TNF agents, anti-IL-17 (secukinumab), and anti-IL-12/23 (ustekinumab)

Table 28. CASPAR Criteria for PsA*

Criterion	Description
1. Evidence of psoriasis	Current, past, or family history
2. Psoriatic nail dystrophy	Onycholysis, pitting, hyperkeratosis
3. Negative results for RF	Preferably by ELISA, nephelometry
4. Dactylitis	Current or past history
5. Radiological evidence	Juxta-articular bone formation on hand or foot x-rays

*To meet the CASPAR (CIASsification criteria for Psoriatic ARthritis) criteria, a patient must have inflammatory articular disease (joint, spine, or entheseal) with ≥3 points from the above 5 categories.
Arthritis Rheum 2006 Aug;54(8):2665-2673. Classification criteria for PsA development

Reactive Arthritis

Definition
- one of the seronegative spondyloarthropathies in which patients have a peripheral arthritis (≥1 mo duration) accompanied by one or more extra-articular manifestations that appears shortly after certain infections of the GI or GU tract
- this term should not be confused with rheumatic fever or viral arthritides

Clinical Triad of Reactive Arthritis
- Arthritis
- Conjunctivitis/uveitis
- Urethritis/cervicitis

Etiology
- onset following an infectious episode either involving the GI or GU tract
  - GI: *Shigella, Salmonella, Campylobacter, Yersinia, C. difficile* species
  - GU: *Chlamydia* (isolated in 16-44% of ReA cases), *Mycoplasma* species
- acute clinical course
  - onset 1-4 wk post-infection
  - lasts wk to mo
  - often recurring
  - spinal involvement persists

"Can't See, Can't Pee, Can't Climb a Tree"
Triad of conjunctivitis, urethritis, and arthritis is 99% specific (but 51% sensitive) for ReA

Epidemiology
- in HLA-B27 patients, axial > peripheral involvement
- M>F

Signs and Symptoms
- **musculoskeletal**
  - asymmetric peripheral arthritis, spondylitis/sacroiliitis, enthesitis (Achilles tendinitis, plantar fasciitis), dactylitis
- **ophthalmic**
  - iritis (anterior uveitis), conjunctivitis
- **dermatologic**
  - keratoderma blennorrhagicum (hyperkeratotic skin lesions on palms and soles) and balanitis circinata (small, shallow, painless ulcers of glans penis and urethral meatus) are diagnostic
- **gastrointestinal**
  - oral ulcers, diarrhea
- **genitourinary**
  - urethritis, prostatitis, cervicitis, cystitis, sterile pyuria; presence not related to site of initiating infection

Investigations
- diagnosis is clinical plus laboratory
- evidence of antecedent or concomitant infection (stool culture, urine, and genital swab testing)
- blood work: normocytic, normochromic anemia, and leukocytosis
- sterile cultures
- serology: HLA-B27 positive, elevated ESR/CRP

Treatment
- antibiotics for non-articular infections
- NSAIDs (naproxen 500 mg BID/TID, diclofenac 50 mg TID, indomethacin 50 mg TID/QID), PT, exercise
- local therapy
  - IA steroid injection (triamcinolone acetonide)
  - topical steroid for ocular involvement
- systemic therapy
  - corticosteroids (starting dose 20 mg/d)
  - DMARDs (for refractory reactive arthritis with peripheral joint involvement only) (SSZ, MTX)
  - TNF-α inhibitors for spinal inflammation (for disease refractory to NSAIDs, DMARDs)

Prognosis
- self-limited, typically 3-5 mo, varies based on pathogen and patient's genetic background
- chronic in 15-20% of cases

Crystal-Induced Arthropathies

Table 29. Gout vs. Pseudogout

Parameter	Gout	Pseudogout
Gender	M>F	M=F
Age	Middle-aged males Post-menopausal females	Usually elderly
Onset of Disease	Acute Can become chronic if high uric acid untreated, people with renal failure, kidney transplant	Acute Chondrocalcinosis is asymptomatic but the clinical feature is generally acute
Crystal Type	Monosodium urate Negative birefringence (yellow when parallel to compensator filter), needle-shaped	CPPD Positive birefringence (blue when parallel), rhomboid-shaped
Distribution	First MTP classically; also midfoot, ankle, knee, or polyarticular	Knee, wrist; monoarticular, or polyarticular if chronic
Radiology (note findings are nonspecific)	Erosions	Chondrocalcinosis OA (knee, wrist, 2nd and 3rd MCP)
Treatment	Acute: NSAIDs, corticosteroids, colchicine Chronic: ± allopurinol, febuxostat	NSAIDs, corticosteroids

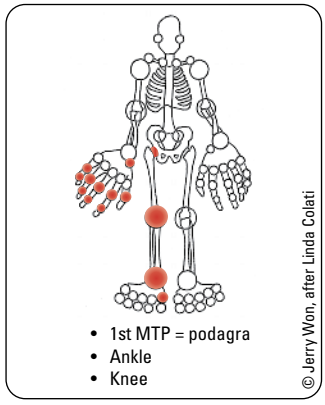

Figure 13. Common sites of involvement of gout (asymmetric joint involvement)

Gout

Definition
- derangement in purine metabolism resulting in hyperuricemia; monosodium urate crystal deposits in tissues (tophi) and synovium (microtophi)

Etiology and Pathophysiology
- uric acid can be obtained from the diet or made endogenously by xanthine oxidase, which converts xanthine to uric acid
- an excess of uric acid results in hyperuricemia
- uric acid can deposit in the skin/subcutaneous tissues (tophi), synovium (microtophi), and kidney, where they can crystalize to form monosodium urate crystals that lead to gout
- non-modifiable risk factors include: genetic mutations, male gender, and advanced age
- modifiable risk factors include: diet (alcohol, purine rich foods such as meats and seafoods, fructose/sugar sweetened foods; see list of precipitants below)
- other risk factors: renal failure, metabolic syndrome, dehydration (e.g. diuretics)

Signs and Symptoms
- single episode progressing to recurrent episodes of acute inflammatory arthritis
- **acute gouty arthritis**
  - severe pain, redness, joint swelling, usually involving lower extremities
  - joint mobility may be limited
  - attack will subside spontaneously within d to wk (5-10 d); may recur
- **tophi**
  - urate deposits on cartilage, tendons, bursae, soft tissues, and synovial membranes
  - common sites: first MTP, ear helix, olecranon bursae, tendon insertions (common in Achilles tendon)
- **kidney**
  - gouty nephropathy
  - uric acid nephrolithiasis

Investigations
- joint aspirate: >90% of joint aspirates show crystals of monosodium urate (negatively birefringent, needle-shaped) if done early in course of presentation
- x-rays may show tophi as soft tissue swelling, bone/joints - punched-out lesions, erosion with "over-hanging" edge
  - U/S shows double-contour sign
- correlated with hyperuricemia in the blood

An acute gout attack may mimic cellulitis; however, joint mobility is usually preserved in cellulitis unless it overlaps a joint

Precipitants of Gout

Drugs are FACT
Furosemide
Aspirin® (low dose)/Alcohol
Cyclosporine
Thiazide diuretics

Foods are SALT
Seafood
Alcohol (beer and spirits)
Liver and kidney
Turkey (meat)

2020 American College of Rheumatology Guideline for the Management of Gout
Arthritis Rheumatol 2020;72:879-95
- Initiate urate lowering therapy (ULT) for patients with:
  - ≥1 SC tophi
  - Radiographic damage attributable to gout
  - Frequent gout flares (≥2/yr)
- Allopurinol is prefered over all other ULTs as a first-line agent for all patients (including CKD stage ≥3)
- Initiate concomitant anti-inflammatory prophylaxis (e.g. colchicine, NSAIDs, prednisone/prednisolone) for 3-6 mo
- Continue ULT to target and maintain serum urate <6 mg/dL
- In patients with frequent gout flares or nonresolving SC tophi who have failed to achieve serum urate <6 mg/dL on uricosurics, xanthine oxidase inhibitors, and other interventions, pegloticase should be initiated and the current ULT should be discontinued
- Gout flares should be managed with NSAIDs, low-dose colchicine, or glucocorticoids as first-line agents

Treatment
- **acute gout**
  - NSAIDs: high dose, then taper as symptoms improve
  - corticosteroids: IA, oral, or IM (if renal, cardiovascular, or GI disease and/or if NSAIDs contraindicated or failed). IV for patients with multiple joints flaring, unable to take oral medication, and already have IV line
  - colchicine 1.2 mg at the first signs of an attack followed by 0.6 mg 1 h later and 0.6 mg BID on subsequent days until the attack has resolved
- **chronic gout**
  - conservative
    - avoid foods with high purine content (e.g. visceral meats, sardines, shellfish, beans, peas)
    - avoid drugs with hyperuricemic effects (e.g. pyrazinamide, ethambutol, thiazide, alcohol)
    - additional management of lifestyle factors: limiting alcohol intake, limiting high-fructose corn syrup, for overweight/obese patients weight loss is recommended (regardless of activity level)
  - medical
    - antihyperuricemic drugs (first line: allopurinol (not nephrotoxic) second line: febuxostat): decrease uric acid production by inhibiting xanthine oxidase. Start low and titrate up. Do not use febuxostat if history of cardiovascular disease
    - uricosuric drugs (probenecid, sulfinpyrazone): very rarely used in combination with allopurinol or febuxostat in patients in whom hyperuricemia is not controlled with the latter
  - prophylaxis with low-dose NSAID/colchicine should be started with urate-lowering therapy
  - in renal disease secondary to hyperuricemia, use low dose allopurinol and monitor Cr
- indications for treatment with antihyperuricemic medications include
  - attacks (>2/yr), tophi, bone erosions/arthritis

Pseudogout (Calcium Pyrophosphate Dihydrate Disease)

Definition
- joint inflammation caused by calcium pyrophosphate (CCP) crystal deposition in connective tissue

Etiology and Pathophysiology
- acute inflammatory arthritis due to phagocytosis of IgG-coated CPPD crystals by neutrophils and subsequent release of inflammatory mediators within joint space
- usually monoarticular but can be polyarticular
- slower onset in comparison to gout, lasts up to 2-3 wk but is self-limited

Risk Factors
- old age, advanced OA, neuropathic joints
- other associated conditions: hyperparathyroidism, hypothyroidism, hypomagnesemia, hypophosphatasia (low ALP), DM, hemochromatosis

Signs and Symptoms
- affects knees, wrists, MCPs, hips, shoulders; less likely elbows, ankles, big toe, spine
- asymptomatic crystal deposition (seen on radiograph only)
- acute crystal arthritis (self-limited flares of acute inflammatory arthritis resembling gout)
- pseudo-OA (progressive joint degeneration, sometimes with episodes of acute inflammatory arthritis)
- pseudo-RA (symmetrical polyarticular pattern with morning stiffness and constitutional symptoms)
- frequently triggered by dehydration, acute illness, surgery, trauma

Investigations
- must aspirate joint to rule out septic arthritis and gout
- CPPD crystals: present in 60% of patients, often only a few crystals, positive birefringence (blue) and rhomboid shaped
- x-rays show chondrocalcinosis in 75%: radiodensities in fibrocartilaginous structures (e.g. knee menisci) or linear radiodensities in hyaline articular cartilage

Treatment
- acute CPP: joint aspiration, steroid injection, cool packs, temporary rest, and protection
- chronic CPP: NSAIDs with gastroprotection and/or low-dose prophylactic colchicine 0.6-1.2 mg/d PO (controversial)

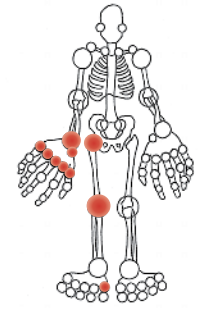

Figure 14. Common sites of involvement of CPPD

EULAR Recommendations for the Management of CPPD

Ann Rheum Dis 2011;70:571-5

1. Pharmacological and non-pharmacological treatment should both be used to manage CPPD.
2. Treating acute CPP crystal arthritis with ice or cool packs, rest, joint aspiration, and IA injection of long-acting glucocorticoids (GCS) may be sufficient for many patients.
3. Acute CPP crystal arthritis can be treated systemically with NSAIDs and low-dose oral colchicine, although their use may be limited in older patients by toxicity and comorbidity.
4. A brief tapering course of oral or parenteral GCS or ACTH may be effective for acute CPP crystal. arthritis that is not amenable to IA GCS injection
5. Low-dose oral colchicine or NSAID can be used as prophylaxis against frequent recurrent acute CPP crystal arthritis.
6. For patients with OA and CPPD, management goals and options are the same as those for OA alone.
7. The order of pharmacological preference for chronic CPP crystal inflammatory arthritis is NSAID and/or colchicine, low-dose corticosteroid, MTX, and hydroxychloroquine.
8. Associated conditions should be treated if detected.
9. There are no disease-modifying treatments for CPP crystal arthritis and no treatment is indicated for asymptomatic chondrocalcinosis.

Non-Articular Rheumatism

Definition
- disorders that primarily affect soft tissues or periarticular structures
- includes bursitis, tendinitis, tenosynovitis, fibromyalgia, and PMR

Polymyalgia Rheumatica

Definition
- characterized by pain and stiffness of the proximal extremities (girdle area)
- closely related to GCA (15% of patients with PMR develop GCA)
- no muscle weakness

Table 30. PMR Classification Criteria Scoring Algorithm*
Required criteria: age >50 yr, bilateral shoulder aching, and abnormal ESR/CRP

	Points without U/S (0-6)	Points with Abnormal U/S** (0-8)
Morning stiffness duration >45 min	2	2
Hip pain or limited ROM	1	1
Absence of RF or ACPA	2	2
Absence of other joint involvement	1	1
At least one shoulder with subdeltoid and/or biceps tenosynovitis and/or glenohumeral synovitis (either posterior or axillary) and at least one hip with synovitis and/or trochanteric bursitis on U/S	N/A	1
Both shoulders with subdeltoid bursitis, biceps tenosynovitis, or glenohumeral synovitis on U/S	N/A	1

*A score of 4 or more is categorized as PMR in the algorithm without U/S and a score of 5 or more is categorized as PMR in the algorithm with U/S
**Optional U/S criteria
Ann Rheum Dis 2012;71:484-492

Epidemiology
- incidence 50 in 100000 per yr in those >50 yr
- age of onset typically >50 yr, F:M=2:1

Signs and Symptoms
- constitutional symptoms prominent (fever, weight loss, malaise)
- pain and stiffness of symmetrical proximal muscles (neck, shoulder and hip girdles, thighs)
- gel phenomenon (stiffness after prolonged inactivity)
- physical exam reveals tender muscles, but no true weakness or atrophy

Investigations
- blood work: often shows anemia of chronic disease, elevated platelets, elevated ESR and CRP, and normal CK; up to 5% of PMR reported with normal inflammatory markers

Treatment
- goal of therapy: symptom relief
- start with prednisone 12.5-25 mg PO once daily, reconsider diagnosis if no response within several days
- taper slowly with improvement over 1 yr period with close monitoring, if in remission taper until discontinued
- relapses should be diagnosed and treated on clinical basis; do not treat a rise in ESR as a relapse
- treat relapses aggressively (50% relapse rate)
- monitor for steroid side effects, glucocorticoid-induced osteoporosis prevention, and follow for symptoms of GCA

Fibromyalgia

Definition
- chronic (>3 mo), widespread (axial, left- and right-sided, upper and lower segment), non-articular pain with characteristic tender points

Diagnosis

Table 31. 2010 ACR Preliminary Diagnostic Criteria for Fibromyalgia

Criteria	Comments
Widespread Pain Index = number of areas in which the patient had pain over the last wk (max score = 19): L and R: shoulder girdle, upper arm, lower arm, hip, upper leg, lower leg, jaw One Area: chest, abdomen, upper back, lower back, neck Symptom Severity (SS) Score = sum of: a) severity of fatigue b) waking unrefreshed c) cognitive symptoms over the past wk d) extent of somatic symptoms (IBS, H/A, abdominal pain/cramps, dry mouth, fever, hives, ringing in ears, vomiting, heartburn, dry eyes, SOB, loss of appetite, rash, hair loss, easy bruising, etc.) All (a-d) rated on 0-3 scale: 0 = no problem, 1 = mild, 2 = moderate, 3 = severe	A patient satisfies diagnostic criteria for fibromyalgia if the following 3 conditions are met: 1. Widespread Pain Index (WPI) ≥7 and SS score ≥5 or WPI 3-6 and SS score ≥9 2. Symptoms have been present at a similar level for at least 3 mo 3. The patient does not have a disorder that would otherwise explain the pain

Arthrit Care and Res 2010;62(5):600-610

Epidemiology
- F:M=3:1
- primarily ages 25-45 yr, some adolescents
- prevalence of 2-5% in general population
- overlaps with chronic fatigue syndrome and myofascial pain syndrome
- strong association with psychiatric illness

Signs and Symptoms
- widespread aching, stiffness
- easy fatigability
- sleep disturbance: non-restorative sleep, difficulty falling asleep, and frequent wakening
- symptoms aggravated by physical activity, poor sleep, emotional stress
- patient feels that joints are diffusely swollen although joint examination is normal
- neurologic symptoms of hyperalgesia, paresthesias, allodynia
- associated with irritable bowel or bladder syndrome, migraines, tension H/As, restless leg syndrome, obesity, depression, and anxiety
- physical exam should reveal only tenderness with palpation of soft tissues, with no specificity for trigger/tender points

Investigations
- blood work: includes TSH; all typically normal unless unrelated, underlying illness present
- serology: do not order ANA or RF unless there is clinical suspicion for a connective tissue disease or inflammatory arthritis
- laboratory sleep assessment

Treatment
- non-pharmacological therapy
  - graded exercise programs including aerobic (>20 min/d, 2-3 d/wk) and resistance training (>8 repetitions per exercise, 2-3 d/wk)
  - other therapies with some evidence: acupuncture, CBT, hydrotherapy, meditative movement (yoga, Tai chi)
  - there is no evidence for biofeedback, chiropractics, hypnotherapy, meditation
- pharmacological therapy (to help with symptoms, not curative)
  - low-dose tricyclic antidepressant (e.g. amitriptyline)
    - for sleep restoration
    - select those with lower anticholinergic side effects
  - SNRI: duloxetine, milnacipran
  - anticonvulsant: pregabalin, gabapentin
  - analgesics may be beneficial for pain that interferes with sleep (NSAIDs, not narcotics)

Prognosis
- variable; usually chronic, waxes and wanes, with some pain and fatigue that usually persists

Table 32. Clinical Features of Inflammatory Myopathy vs. Polymyalgia Rheumatica vs. Fibromyalgia

	Polymyositis	PMR	Fibromyalgia
Epidemiology	F>M, 40-50 yr	F>M, >50 yr	F>M, 25-45 yr
Muscle Involvement	Proximal muscle	Proximal muscle	Diffuse
Weakness	Yes	No	No
Pain	Painless	Painful	Painful
Stiffness	Present	Significant morning and gelling stiffness (shoulders, neck, hips)	May have morning stiffness
Investigations	Muscle biopsy, CK, EMG, rule out malignancy	ESR/CRP, rule out GCA	Sleep assessment, TSH
ESR/CRP	Usually normal	Markedly elevated	Normal
Treatment	High-dose steroids, immunosuppressants	Low-dose steroids	Exercise, sleep restoration

Common Medications

Table 33. Common Medications for Osteoarthritis

Class	Generic Drug Name	Trade Name	Dosing (PO)	Indications	Contraindications	Adverse Effects
Analgesic	acetaminophen	Tylenol®	1 mg PO TID q4 h (3 g daily max)	1st line	Severe liver disease/ impairment	Hepatotoxicity Overdose Potentiates warfarin
NSAIDs	ibuprofen diclofenac diclofenac/ misoprostol naproxen meloxicam	Advil® Voltaren® Arthrotec® Naprosyn® Aleve® Mobicox®	200-600 mg TID 25-50 mg TID 50-75/200 mg TID 125-500 mg BID 7.5-15 mg once daily	2nd line	GI bleed Renal impairment Allergy to ASA, NSAIDs Pregnancy (T3) Anticoagulants	Nausea, tinnitus, vertigo, rash, dyspepsia, GI bleed, PUD, hepatitis, renal failure, HTN, nephrotic syndrome
COX-2 Inhibitors	celecoxib	Celebrex®	200 mg once daily	Dyspepsia/GERD	Renal impairment Cardiovascular disease GI Bleed	Same as NSAIDs above

Other Treatments	Comments
Combination analgesics (acetaminophen + codeine, acetaminophen + NSAIDs)	Enhanced short-term effect compared to acetaminophen alone More adverse effects: sedation, constipation, nausea, GI upset
IA corticosteroid injection	Short-term (wk-mo), joint specific treatment Decrease in pain and improvement in function Used for management of an IA inflammatory process when infection has been ruled out
IA hyaluronic acid q6 mo	Used for mild-moderate OA of the knees; however, little supporting evidence and not considered to be effective Precaution with chicken/egg allergy
Topical NSAIDs	Topical diclofenac (Pennsaid®, Voltaren Emulgel®) May use for patients who fail acetaminophen treatment and who wish to avoid systemic therapy, better on small joints
Capsaicin cream	Mild decrease in pain
Glucosamine sulfate ± chondroitin	Limited evidence of benefit in OA knee. No regulation by Health Canada

Table 34. DMARDs

Generic Drug Name	Trade Name	Dosing	Contraindications	Adverse Effects
COMMONLY USED				
hydroxychloroquine $	Plaquenil®	400 mg PO once daily initially 200-400 mg PO once daily maintenance (5 mg/kg ideal body weight per day to a maximum of 400 mg/d)	Retinal disease, G6PD deficiency	GI symptoms, skin rash, macular damage, neuromyopathy Requires annual ophthalmological screening to monitor for retinopathy
sulfasalazine $	Salazopyrim® Azulfidine® (US)	1000 mg PO BID-TID	Sulfa/ASA allergy, kidney disease, G6PD deficiency	GI symptoms, rash, H/A, leukopenia
methotrexate $	Rheumatrex® Folex/Mexate®	7.5-25 mg PO/SC weekly	Bone marrow suppression, liver disease, significant lung disease, immunodeficiency, pregnancy, EtOH use	Oral ulcers, GI symptoms, cirrhosis, myelosuppression, pneumonitis, tubular necrosis
leflunomide $$	Arava®	10-20 mg PO once daily	Liver disease, lung disease, pregnancy	Alopecia, GI symptoms, liver dysfunction, interstitial pulmonary fibrosis, HTN
NOT COMMONLY USED				
cyclosporine $$	Neoral®	2.5-3 mg/kg/d divided and given in 2 doses PO	Kidney/liver disease, infection, HTN	HTN, decreased renal function, hair growth, tremors, bleeding
gold (injectable) $	Solganal® Myochrysine®	50 mg IM weekly after gradual introduction	IBD, kidney/liver disease	Rash, mouth soreness/ulcers, proteinuria, marrow suppression
azathioprine $	Imuran®	2 mg/kg/d PO once daily	Kidney/liver disease thiopurine S-methyltransferase (TPMT) deficiency	Rash, pancytopenia (especially ↓ WBC, ↑ AST, ALT), biliary stasis, vomiting, diarrhea
cyclophosphamide $	Cytoxan®	1 g/m²/mo IV as per protocol	Kidney/liver disease, neutropenia	Cardiotoxicity, GI symptoms, hemorrhagic cystitis, nephrotoxicity, bone marrow suppression, sterility, bladder cancer
NEWER DMARDs (Biologics)				
etanercept $$$	Enbrel®	25 mg biweekly or 50 mg weekly SC	Fusion protein of TNF receptor and Fc portion of IgG	
infliximab $$$	Remicade®	3-5 mg/kg IV q8 wk	Chimeric mouse/human monoclonal anti-TNF	
adalimumab $$$	Humira®	40 mg SC q2 wk	Monoclonal anti-TNF	
golimumab $$$	Simponi®	50 mg SC q1 mo or 2 mg/kg q8 wk	Monoclonal anti-TNF	
certolizumab $$$	Cimzia®	400 mg SC q2 wk x3 then 200 mg SC q4 wk	PEGylated monoclonal anti-TNF	
apremilast $$$	Otezla®	Day 1: 10 mg (AM) PO, titrate up to 30 mg BID by day 6	Inhibitor of PDE4 which inhibits production of TNF-α	
abatacept $$$	Orencia®	500-1000 mg IV infusion q1 mo or 125 mg SC q1 wk	Costimulation modulator of T cell activation	
rituximab $$$	Rituxan®	1 g x2 IV infusions, 2 wk apart q6 mo	Causes B cell depletion, binds to CD20	
tocilizumab $$$	Actemra®	4-8 mg/kg IV q4 wk or 162 mg SC q1-2 wk	IL-6 receptor antagonist	
tofacitinib $$	Xeljanz®	5 mg BID	Inhibits the JAK enzyme and thus interferes with JAK-STAT signaling pathway	
secukinumab $$$	Cosentyx	150 mg monthly	Blocks IL-17	

Risks of Biologics
Patients require negative TB skin test, CXR, and negative hepatitis B virus serology prior to starting any of these medications. Increased risk of: serious infections, worsening heart failure, multiple sclerosis, and positive auto-antibodies
Immunizations (flu, pneumonia, shingles, hepatitis B) should ideally be completed 2 wk prior to starting biologics

Landmark Rheumatology Trials

Trial Name	Reference	Clinical Trial Details
RHEUMATOID ARTHRITIS		
COMET	Lancet 2008;372:375-82	**Title**: Comparison of Methotrexate Monotherapy with A Combination of Methotrexate and Etanercept in Active, Early, Moderate to Severe Rheumatoid Arthritis (COMET): A Randomised, Double-Blind, Parallel Treatment Trial **Purpose**: To compare the efficacy of MTX monotherapy or MTX plus etanercept for remission and radiographic non-progression in RA patients. **Methods**: 542 RA MTX-naive outpatients with moderate-to-severe disease for 3-24 mo were randomly assigned to MTX alone (titrated from 7.5-20 mg/wk) or MTX (same titration) plus etanercept 50 mg/wk. **Results**: Clinical remission was achieved in 50% of patients on combined treatment vs. 28% taking MTX alone (difference, 22.05%; P<0.0001). 80% and 59%, respectively, achieved radiographic non-progression (difference, 20.98%; P<0.0001). Both groups experienced similar adverse events. **Discussion:** 1 yr of treatment with etanercept plus MTX can achieve clinical remission and radiographic non-progression in early severe RA.
ERA	NEJM 2000;343:1586-93	**Title**: A Comparison of Etanercept and Methotrexate in Patients with Early Rheumatoid Arthritis **Purpose**: To investigate the efficacy of etanercept in reducing disease activity and joint damage in patients with early and active RA. **Methods**: 632 patients received either SC etanercept (10 or 25 mg/wk) twice weekly or oral MTX (19 mg/wk) for 12 mo. Clinical response was defined by criteria of the American College of Rheumatology. **Results**: Patients on 25 mg etanercept improved quicker than those on MTX, with significantly more improvements in disease activity within 6 mo (P<0.05). During the first 6 and 12 mo, there were significantly greater increases in mean erosion scores in the MTX group (P=0.007). Fewer adverse events (P=0.02) and infections (P=0.006) were seen in 25 mg etanercept. **Conclusion**: In patients with early active RA, etanercept more rapidly reduced symptoms and slowed joint damage as compared to MTX.
BeSt	Arthritis Rheum 2005;52:3381-90	**Title**: Clinical and Radiographic Outcomes of Four Different Treatment Strategies in Patients with Early Rheumatoid Arthritis (the BeSt Study): A Randomized, Controlled Trial **Purpose**: To identify the optimal therapeutic strategy for preventing long-term joint damage and functional decline in RA. **Methods**: 508 patients were randomly assigned to 1 of 4 therapeutic strategies: (1) sequential disease-modifying. antirheumatic drug monotherapy, (2) step-up combination therapy, (3) initial combination therapy with tapered high-dose prednisone, or (4) initial combination therapy with infliximab. **Results**: At 3 mo, groups 3 and 4 showed significantly greater functional improvement (as defined by the Dutch version of the Health Assessment Questionnaire (D-HAQ)) with mean scores of 0.6, as compared to mean scores of 1.0 in groups 1 and 2 (P<0.001). At 1 yr, mean D-HAQ scores in groups 3 and 4 were 0.5, as compared to 0.7 in groups 1 and 2 (P=0.009). **Conclusion**: As compared to sequential monotherapy or step-up combination therapy, initial combination therapy with prednisone or infliximab led to earlier functional improvements and less radiographic damage in patients with early RA.
Infliximab and MTX	NEJM 2000;343:1594-602	**Title**: Infliximab and Methotrexate in the Treatment of Rheumatoid Arthritis. Anti-Tumor Necrosis Factor Trial in Rheumatoid Arthritis ith Concomitant Therapy Study Group **Purpose**: To assess infliximab for potential sustained benefits and effects on joint damage in RA. **Methods**: 428 patients who had active RA despite MTX therapy were treated with IV infliximab (3 or 10 mg/kg every 4 or 8 wk plus oral MTX for 54 wk) or placebo. **Results**: As compared to MTX alone, infliximab plus MTX significantly reduced signs and symptoms of RA (clinical response, 51.8% vs. 17.0%; P<0.001). There was greater evidence of joint damage on MTX alone but not on infliximab plus MTX (mean change in radiographic score, 7.0 vs. 0.6, P<0.001). **Conclusion**: Repeated doses of infliximab plus MTX in persistently active RA was clinically effective and slowed the progression of joint damage.
Treatment of Active Rheumatoid Arthritis With Leflunomide Compared With Placebo and Methotrexate. Leflunomide Rheumatoid Arthritis Investigators Group. Strand et al. 1999	Arch Intern Med 1999;159:2542-50	**Title**: Treatment of Active Rheumatoid Arthritis with Leflunomide Compared with Placebo and Methotrexate. Leflunomide Rheumatoid Arthritis Investigators Group **Purpose**: To compare the safety and efficacy of leflunomide vs. MTX in patients with active RA. **Methods**: 482 patients with active RA were randomly assigned to receive leflunomide (20 mg/d), MTX (7.5-15 mg/wk), or placebo. **Results**: Clinical response and success rates on leflunomide (52% and 41%) and MTX (46% and 35%) were significantly greater than those on placebo (26% and 19%) (P<0.001). On leflunomide, common adverse events included gastrointestinal complaints, skin rash, and reversible alopecia. **Conclusion**: In patients with active RA, leflunomide was associated with better clinical responses than placebo and had similar efficacies as MTX.
PREMIER	Arthritis Rheum 2006;54:26-37	**Title**: The PREMIER Study: a Multicenter, Randomized, Double-Blind Clinical Trial of Combination Therapy with Adalimumab Plus Methotrexate Versus Methotrexate Alone or Adalimumab Alone in Patients With Early, Aggressive Rheumatoid Arthritis Who Had Not Had Previous Methotrexate Treatment. **Purpose**: To compare the efficacy and safety of adalimumab plus MTX versus MTX alone or adalimumab alone in patients with early, aggressive RA who were MTX-naive. **Methods**: 799 patients with active disease <3 yr were randomly assigned to adalimumab 40 mg SC every other wk plus oral MTX, adalimumab 40 mg SC every other wk, or oral MTX weekly. **Results**: American College of Rheumatology 50% improvement was achieved in significantly more patients on combination therapy (62%) than MTX or adalimumab (46% and 41%, respectively; both P<0.001). Patients on combination therapy had significantly less radiographic progression (P<0.002) than those on either monotherapy. 49% of patients on combination therapy achieved remission at 2 yr. **Conclusion**: Adalimumab plus MTX was significantly superior to either MTX or adalimumab alone in early, aggressive RA.

Trial Name	Reference	Clinical Trial Details
OSTEOARTHRITIS		
Hyaluronan	Ann Rheum Dis 2010;69:1097-1102	**Title**: Intra-Articular Hyaluronan is without Clinical Effect in Knee Osteoarthritis: a Multicentre, Randomised, Placebo-Controlled, Double-Blind Study of 337 Patients Followed for 1 Year **Purpose**: To assess the long-term safety and efficacy of 5 hyaluronan IA injections in knee osteoarthritis. **Methods**: 337 patients with knee osteoarthritis and a Lequesne algofunctional index score (LFI) ≥10 received IA hyaluronan product (sodium hyaluronate; Hyalgan®) or saline weekly for 5 wk. **Results**: Treatment had no significant effect on time to recurrence or baseline change in LFI or walking pain. There were also no significant differences in paracetamol consumption, patients' global assessment, responder rates, or adverse events. **Conclusion**: Hyaluronan injections were not clinically effective in patients with osteoarthritis of the knee with moderate-severe disease (LFI≥10).
SYSTEMIC LUPUS ERYTHEMATOSUS		
Belimumab	Lancet 2011;377:721-31	**Title**: Efficacy and Safety of Belimumab in Patients with Active Systemic Lupus Erythematosus: a Randomised, Placebo-Controlled, Phase 3 Trial **Purpose**: To assess the efficacy and safety of belimumab in patients with active SLE. **Methods**: 867 patients (aged ≥18 yr) who were seropositive with scores of ≥6 on SELENA-SLEDAI were randomly assigned to belimumab 1 mg/kg or 10 mg/kg, or placebo plus standard of care (based on disease manifestation and local guidelines). **Results**: Significantly higher SRI (SLE Responder Index) rates occurred with belimumab 1 mg/kg (51%, OR 1.55; P=0.0129) and 10 mg/kg (58%, 1.83; P=0.0006) than placebo (44%). There was a greater frequency of SELENA-SLEDAI reduction by ≥4 points with belimumab 1 mg/kg (53%, 1.51; P=0.0189) and 10 mg/kg (58%, 1.71; P=0.0024) than placebo (46%). **Conclusion**: Belimumab may be the first targeted biologic that is specifically approved for SLE.
Mycophenolate Mofetil or Intravenous Cyclophosphamide for Lupus Nephritis. Ginzler et al. 2005	NEJM 2005;353:2219-28	**Title**: Mycophenolate Mofetil or Intravenous Cyclophosphamide for Lupus Nephritis **Purpose**: To investigate if mycophenolate mofetil is effective for treating lupus nephritis. **Methods**: 140 patients with active lupus nephritis were randomly assigned to oral mycophenolate mofetil (1000 mg/d increased to 3000 mg/d) or monthly IV cyclophosphamide (0.5 g/m2 increased to 1.0 g/m^2). **Results**: 22.5% of patients on mycophenolate mofetil and 5.8% of those on cyclophosphamide experienced complete remission (absolute difference, 16.7%; 95% CI, 5.6-27.9%; P=0.005), thus demonstrating that mycophenolate mofetil is more efficacious than cyclophosphamide. **Conclusion**: In active lupus nephritis, mycophenolate mofetil was more effective than IV cyclophosphamide in inducing remission and had a better safety profile.
CONNECTIVE TISSUE DISORDERS		
Azathioprine or Methotrexate Maintenance for ANCA-Associated Vasculitis. Pagnoux et al. 2008	NEJM 2008;359:2790-803	**Title**: Azathioprine or Methotrexate Maintenance for ANCA-Associated Vasculitis **Purpose**: To compare azathioprine and MTX for safety and efficacy in Wegener's granulomatosis and microscopic polyangiitis. **Methods**: 159 patients who achieved remission with IV cyclophosphamide and corticosteroids were randomly assigned to receive oral azathioprine (AZA) or MTX for 12 mo. **Results**: The rates of adverse events (requiring discontinuation of the study drug or causing death) were not significantly different between groups. Event-free survival was also not significantly different between groups. **Conclusion**: In patients with Wegener's granulomatosis and microscopic polyangiitis, AZA and MTX are similar alternatives for maintenance therapy after initial remission.
CYCLOPS	Ann Intern Med 2009;150:670-80	**Title**: Pulse Versus Daily Oral Cyclophosphamide for Induction of Remission in Antineutrophil Cytoplasmic Antibody-Associated Vasculitis: a Randomized Trial **Purpose**: To compare the efficacy of pulse cyclophosphamide vs. daily oral cyclophosphamide for inducing remission in ANCA-associated vasculitis. **Methods**: 149 patients with newly diagnosed generalized ANCA-associated vasculitis with renal involvement received cyclophosphamide 15 mg/kg every 2-3 wk (pulse), or daily cyclophosphamide 2 mg/kg orally, plus prednisolone. **Results**: There was no significant difference in time to remission (P=0.59) or percentage of patients who went into remission at 9 mo (88.1% in pulse vs. 87.7% in oral). The oral group had higher cumulative cyclophosphamide doses (P<0.001). Lower rates of leukopenia were seen in the pulse group (hazard ratio, 0.41; 95% CI, 0.23 to 0.71). **Conclusion**: In ANCA-associated vasculitis, pulse cyclophosphamide induced remission as effectively as the daily oral regimen, required less cumulative cyclophosphamide, and caused fewer cases of leukopenia.
Cyclophosphamide vs. Placebo in Scleroderma Lung Disease. Tashkin et al. 2006	NEJM 2006;354:2655-66	**Title**: Cyclophosphamide Versus Placebo in Scleroderma Lung Disease **Purpose**: To determine the efficacy of oral cyclophosphamide in patients with active alveolitis and scleroderma-related ILD. **Methods**: 158 patients with scleroderma, restrictive lung physiology, dyspnea, and evidence of inflammatory interstitial lung disease received oral cyclophosphamide (≤2 mg/kg/d) or placebo for 1 yr. **Results**: The mean absolute difference in 12-mo adjusted FVC between cyclophosphamide and placebo was 2.53% (95% CI, 0.28 to 4.79%), indicating great efficacy of cyclophosphamide (P<0.03). The difference in FVC between groups was sustained at 24 mo. **Conclusion**: In patients with symptomatic scleroderma-related ILD, oral cyclophosphamide had significant clinical benefit.
Etanercept Plus Standard Therapy for Granulomatosis with Polyangiitis Update to: WGET	NEJM 2005;352:351-361	**Title**: Etanercept Plus Standard Therapy for Wegener's Granulomatosis **Purpose**: To investigate the safety and efficacy of etanercept for remission maintenance in GPA. **Methods**: 180 patients with GPA were randomly assigned to receive either etanercept or placebo, in addition to standard treatment (glucocorticoids plus cyclophosphamide or MTX). **Results**: No significant differences were observed between the etanercept and control groups in the rates of stable periods of low-level disease activity (86.5% vs. 90.6%, P=0.32), sustained remission (69.7% vs. 75.3%, P=0.39), or the time necessary to reach those outcomes. Disease flares and adverse events were common in both groups but not significantly different. **Conclusion**: Etanercept is not effective for remission maintenance in GPA.
Mycophenolate Mofetil vs. Azathioprine for Maintenance in ANCA-Associated Vasculitis Update to: IMPROVE	JAMA 2010;304:2381-88	**Title**: Mycophenolate Mofetil vs. Azathioprine for Remission Maintenance in Antineutrophil Cytoplasmic Antibody-Associated Vasculitis: a Randomized Controlled Trial **Purpose**: To compare the efficacy of mycophenolate mofetil vs. azathioprine (AZA) preventing relapses in patients with AAV. **Methods**: Following remission induction with cyclophosphamide and prednisolone,156 patients with newly diagnosed AAV were randomly assigned to azathioprine (initiated at 2 mg/kg/d) or mycophenolate mofetil (initiated at 2000 mg/d). **Results**: The mycophenolate mofetil group experienced significantly more relapses (55%) as compared to AZA (37.5%) (hazard ratio for mycophenolate mofetil, 1.69, 95% CI, 1.06-2.70; P=0.03). There was no significant difference in the rates of severe adverse events between groups. **Conclusion**: Mycophenolate mofetil was less effective than AZA for maintaining disease remission in AAV.

Trial Name	Reference	Clinical Trial Details
Rituximab vs. Cyclophosphamide for ANCA-Associated Vasculitis Update to: RAVE	NEJM 2010;363:221-32	**Title**: Rituximab Versus Cyclophosphamide for ANCA-Associated Vasculitis **Purpose**: To investigate if rituximab is more effective and/or safer than a cyclophosphamide for treating AAV. **Methods**: 197 ANCA-positive patients randomly assigned to receive rituximab (375 mg/m^2 for 4 wk) or cyclophosphamide (2 mg/kg/d). **Results**: 64% of the rituximab group reached the primary endpoint (remission of disease without the use of prednisone at 6 mo), as compared with 53% of controls (noninferiority, P<0.001). Rituximab was more effective than cyclophosphamide for inducing remission of relapsing disease; 67% vs. 42% reached the primary endpoint (P=0.01). **Conclusion**: In severe AAV, rituximab was noninferior to cyclophosphamide for remission induction and may be superior in relapsing disease.
GOUT		
Febuxostat Compared with Allopurinol in Patients with Hyperuricemia and Gout. Becker et al. 2005	NEJM 2005;353:2450-61	**Title**: Febuxostat Compared with Allopurinol in Patients with Hyperuricemia and Gout **Purpose**: To investigate the use of febuxostat as a potential alternative to allopurinol for patients with hyperuricemia and gout. **Methods**: 762 patients with gout and with serum urate ≥8.0 mg/dL were randomly assigned to receive either daily febuxostat (80 or 120 mg) or daily allopurinol (300 mg) for 52 wk. **Results**: Primary endpoint (serum urate <6.0 mg/dL at the last 3 monthly measurements) occured in 53% of patients on febuxostat 80 mg, 62% on febuxostat 120 mg, and 21% on allopurinol (P<0.001 for both febuxostat groups vs. allopurinol). The overall incidence of gout flares during wk 9-52 was similar in all groups and decreased with continued treatment. **Conclusion**: In patients with hyperuricemia and gout, febuxostat was more effective than allopurinol at lowering serum urate.
ANKYLOSING SPONDYLITIS		
Adalimumab Update to: ATLAS	Arthritis Rheum 2006;54:2136-46	**Title**: Efficacy and Safety of Adalimumab in Patients with Ankylosing Spondylitis: Results of a Multicenter, Randomized, Double-Blind, Placebo-Controlled Trial **Purpose**: To assess the safety and efficacy of adalimumab in patients with active AS. **Methods**: 208 AS patients were randomly assigned to SC injection of adalimumab (40 mg every other wk) or placebo for 24 wk. Primary outcome was a 20% response according to the Assessment in AS International Working Group (ASA20). **Results**: 58.2% of adalimumab-treated patients reached an ASAS20 response at wk 12 vs. 20.6% of placebo-treated patients (P<0.001). Adalimumab also demonstrated significantly greater ASAS40 and ASAS5/6 responses at wk 12 and 24 (P<0.001). Significantly more adverse events were seen with adalimumab. **Conclusion**: Adalimumab was well-tolerated and clinically effective in treating active AS.
ASSERT	Arthritis Rheum 2005;52:582-91	**Title**: Efficacy and Safety of Infliximab in Patients with Ankylosing Spondylitis: Results of a Randomized, Placebo-Controlled Trial (ASSERT) **Purpose**: To evaluate the efficacy and safety of infliximab in AS. **Methods**: 279 patients were randomly assigned to receive 5 mg/kg infliximab infusions at wk 0, 2, 6, 12, and 18, or placebo. Primary outcome was a 20% response according to the Assessment in AS International Working Group (ASA20). **Results**: As compared with placebo, significantly more patients on infliximab achieved the primary outcome (61.2% vs. 19.2%)(P<0.001). Infliximab produced clinical benefits beginning at wk 2 that were sustained over the 24 wk. Adverse events were common in both groups but generally mild-moderate in severity. **Conclusion**: In patients with AS, infliximab was clinically effective and well tolerated over 24 wk.
SPINE	Ann Rheum Dis 2011;70:799-804	**Title**: Efficacy of Etanercept on Rheumatic Signs and Pulmonary Function Tests in Advanced Ankylosing Spondylitis: Results of a Randomized Double-Blind Placebo-Controlled Study (SPINE) **Purpose**: To assess the efficacy of etanercept (ETN) in advanced AS. **Methods**: 82 patients with severe, active AS that were refractory to NSAIDs and anti-TNF naive were treated with ETN 50 mg once per wk or placebo. **Results**: Over 12 wk, there were significantly greater improvements in the Bath AS Disease Activity Index (BASDAI) in the ETN group vs. placebo group (-19.8±16.5 vs. -11.0±16.4, P=0.019). ETN also improved CRP levels (P<0.001), total back pain (P=0.010), and FVC (P=0.006). **Conclusion**: In advanced AS, ETN has short-term efficacy for improving pain, CRP, spinal mobility and pulmonary function.
Sulfasalazine	Arthritis Rheum 1995;38:618-27	**Title**: Sulfasalazine in the Treatment of Spondylarthropathy. A Randomized, Multicenter, Double-Blind, Placebo-Controlled Study **Purpose**: To evaluate the safety and efficacy of SSZ in treating spondylarthropathy. **Methods**: 351 patients with active disease despite treatment with NSAIDs received SSZ (3 g/d) or placebo. Primary efficacy outcomes included the patient's and physician's overall assessments, pain, and morning stiffness. **Results**: 60% of patients taking SSZ improved by at least 1/5 points on patient assessment of disease activity, in contrast to 44% taking placebo (only significant difference among 4 primary outcomes). SSZ had greater clinical efficacy in a subgroup of patients with psoriatic arthritis, as measured by primary efficacy variables and joint inflammation. **Conclusion**: SSZ was more effective than placebo in treating active spondylarthropathy, particularly in patients with psoriatic arthritis.

Acronyms

ADT	androgen deprivation therapy
AFP	alpha-fetoprotein
ART	assisted reproductive technologies
ASA	acetylsalicylic acid
AUA	American Urological Association
BBD	bladder and bowel dysfunction
BCG	Bacillus Calmette-Guérin
BPH	benign prostatic hyperplasia
BPKVP	bipolar plasma kinetic vaporization of the prostate
CAH	congenital adrenal hyperplasia
CaP	cancer of the prostate
CBI	continuous bladder irrigation
CF	cystic fibrosis
CFU	colony-forming unit
CHF	congestive heart failure
CIC	clean intermittent catheterization
CIS	carcinoma *in situ*
CMG	cystometrogram
CRPC	castrate-resistant prostate cancer
CTU	CT urography
CUA	Canadian Urological Association
CVA	costovertebral angle
d/c	discharge
DHT	dihydrotestosterone
DMSA	dimercaptosuccinic acid
DRE	digital rectal exam
DSD	detrusor sphincter dyssynergia
EBRT	external beam radiation therapy
ED	erectile dysfunction
EPS	expressed prostatic secretions
FNA	fine needle aspiration
GA	general anesthesia
GAG	glycosaminoglycan
HIFU	high-intensity focused ultrasound
HPF	high power field
HPTA	hypothalamic-pituitary-testicular axis
ICSI	intracytoplasmic sperm injection
IFN-α	interferon-alpha
IL-2	interleukin-2
IPSS	International Prostate Symptom Score
ISD	intrinsic sphincter deficiency
IUI	intrauterine insemination
IVF	*in vitro* fertilization
IVP	intravenous pyelogram
KUB	kidneys, ureters, bladder
LFT	liver function test
LMN	lower motor neuron
LUTS	lower urinary tract symptoms
MET	medical expulsive therapy
MS	multiple sclerosis
MVC	motor vehicle collisions
NMIBC	non-muscle invasive bladder cancer
NSGCT	non-seminomatous germ cell tumour
OAB	overactive bladder
OPQRSTU	onset, position, quality, radiation, severity, temporality, déjà vu
PCa	prostate cancer
PCKD	polycystic kidney disease
PCNL	percutaneous nephrolithotomy
PDE	phosphodiesterase
PFMT	pelvic muscle floor training
PGE1	prostaglandin E1
PID	pelvic inflammatory disease
PLND	pelvic lymph node dissection
PMC	pontine micturition centre
POD	post-obstructive diuresis
PSA	prostate specific antigen
PUV	posterior urethral valve
PVD	peripheral vascular disease
PVP	photoselective vaporization of the prostate (GreenLight™ Laser)
PVR	post-void residual
QOL	quality of life
RCC	renal cell carcinoma
RCT	randomized controlled trial
RFA	radio-frequency ablation
RP	radical prostatectomy
RPLND	retroperitoneal lymph node dissection
RR	respiratory rate
RTA	renal tubular acidosis
RUG	retrograde urethrogram
SA	semen analysis
SCC	squamous cell carcinoma
SEEK PP	*Staphylococcus saprophyticus, E. coli, Enterococcus, Klebsiella, Proteus, Pseudomonas*
SFU	Society of Fetal Urology
SLN	sentinel lymph node
SUI	stress urinary incontinence
SWL	(extracorporeal) shockwave lithotripsy
TNM	tumour node metastasis
TMP/SMX	trimethoprim/sulfamethoxazole
TRUS	transrectal ultrasound
TUIP	transurethral incision of the prostate
TUMT	transurethral microwave therapy
TURBT	transurethral resection of bladder tumour
TURP	transurethral resection of the prostate
U/O	urine output
UC	urothelial carcinoma
UMN	upper motor neuron
UPJ	ureteropelvic junction
URS	ureterorenoscopy
UTD	urinary tract dilation
UTI	urinary tract infection
UVJ	ureterovesical junction
VB1	voided bladder, initial (urethra)
VB2	voided bladder, midstream (bladder)
VB3	voided bladder, post-massage/ digital rectal exam
VCUG	voiding cystourethrogram
VIU	visual internal urethrotomy
VUR	vesicoureteral reflux
WHO	World Health Organization

Basic Anatomy Review

- recall that the anatomical position of the penis is erect; therefore, the anatomical ventral side of the penis appears to be the dorsal side of the flaccid penis

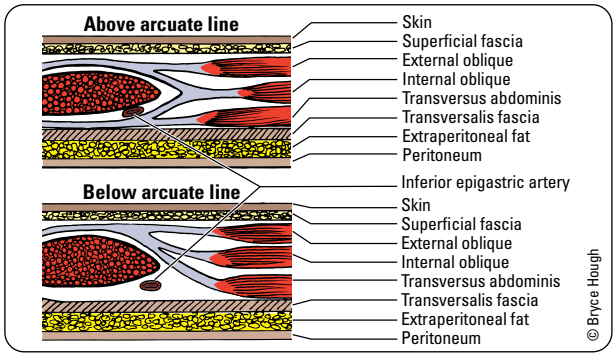

Figure 1. Midline cross-section of abdominal wall

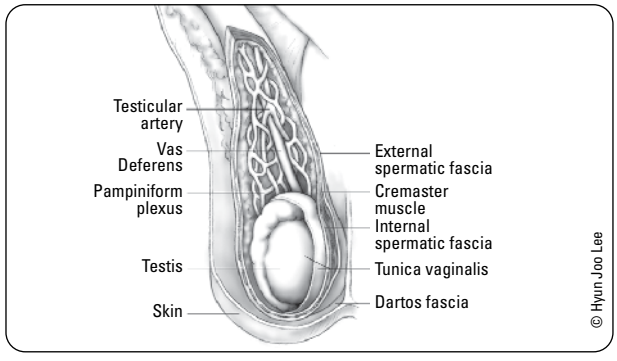

Figure 2. Anatomy of scrotum

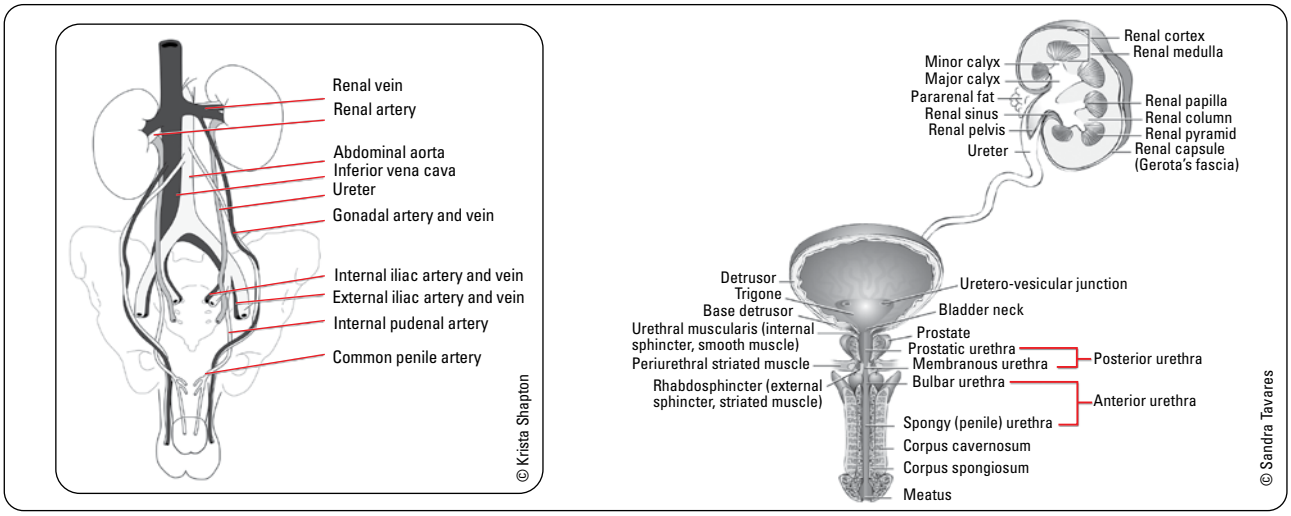

Figure 3. Essential male genitourinary tract anatomy

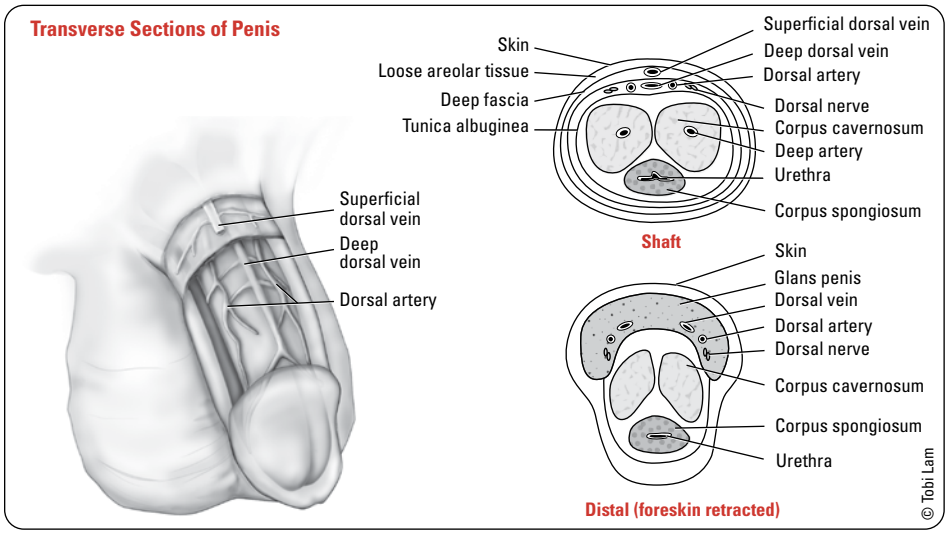

Figure 4. Cross section of the penis

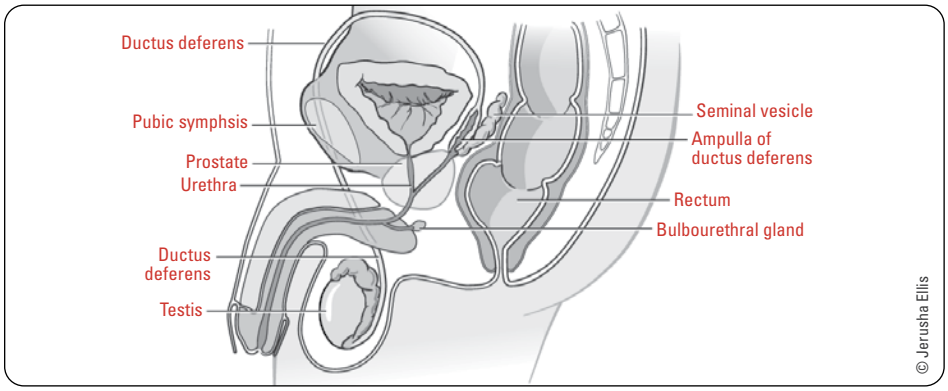

Figure 5. Median sagittal section of the male pelvis and perineum

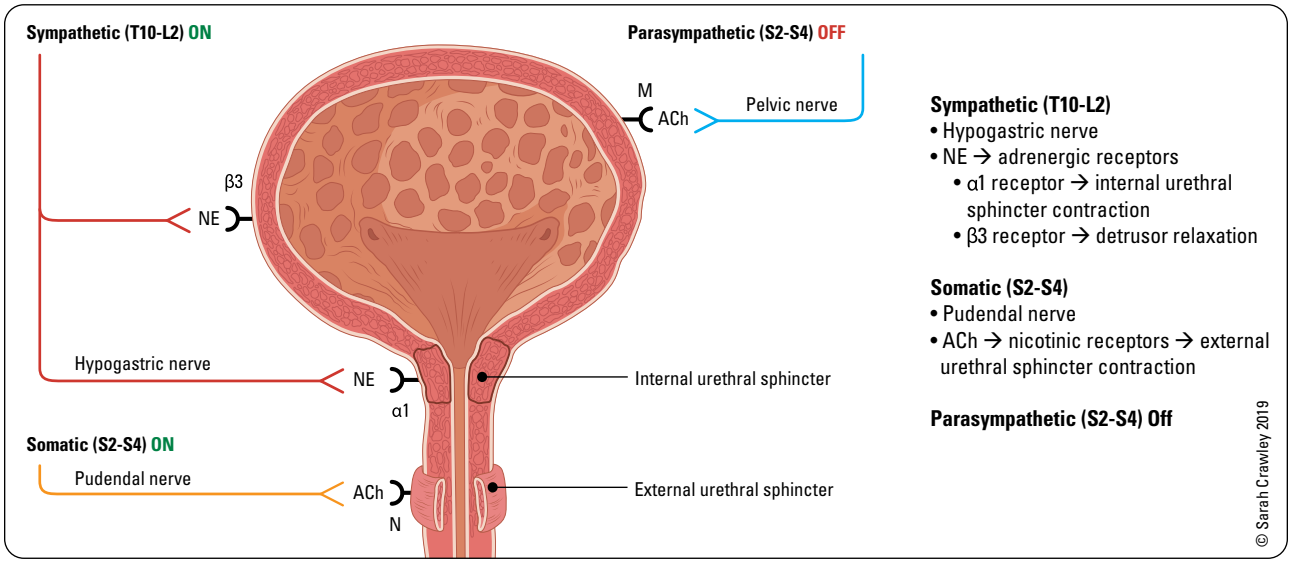

Figure 6. Bladder innervation during storage phase

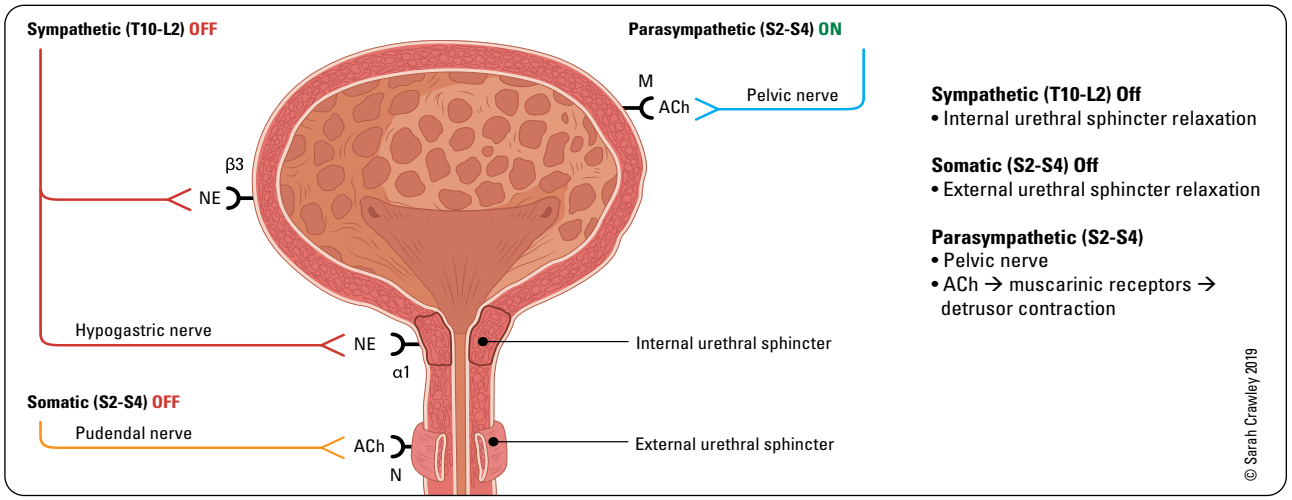

Figure 7. Bladder innervation during voiding phase

Urologic History

- follow OPQRSTU approach
  - note that pain may not be limited to the genital region (e.g. lower abdomen, CVA)
- urinary habits
  - LUTS (see *Lower Urinary Tract Symptoms*, U7)
  - storage symptoms (FUN): frequency, urgency (rush to toilet), nocturia
  - voiding symptoms (SHED): stream changes/straining, hesitancy, incomplete emptying, post-void dribbling
  - dysuria: burning, pain on voiding
  - hematuria: blood clots, red/pink tinged urine (see *Hematuria*)
  - incontinence: stress, urgency, mixed, overflow (see *Urinary Incontinence*, U6)
- sexual function
  - scrotal mass (see *Scrotal Masses*, U32)
  - ED (see *Erectile Dysfunction*, U33)
  - female sexual dysfunction (dyspareunia, low desire, arousal disorder, orgasmic dysfunction)
  - infertility (see *Infertility*, U37)
- associated symptoms
  - N/V
  - bowel dysfunction
- constitutional symptoms
  - fever, chills, unintentional weight loss, night sweats, fatigue, malaise, bone pain
- risk factors: past urologic disease (e.g. UTI, stones, STI, cancers, anatomic abnormalities), FMHx, medications, lifestyle factors (e.g. smoking, alcohol, inactivity), trauma, previous surgical procedures

Always ask about sexual function on history. Change in erectile function can be one of the first symptoms that there is concomitant vascular disease. If there is new onset ED, consider screening for DM and CAD risk factors

Hematuria

Macroscopic (Gross) Hematuria

Gross, painless hematuria in adults is bladder cancer until proven otherwise

Definition
- blood in the urine that can be seen with the naked eye

Classification
- see Nephrology

Etiology

Table 1. Etiology by Age Group

Age (yr)	Etiology	
0-20	UTI, glomerulonephritis, congenital abnormalities	
20-40	UTI, stones, bladder tumour, exercise	
40-60	Male: bladder tumour, stones, UTI, prostate cancer	Female: UTI, stones, bladder tumour
>60	Male: BPH, bladder tumour, UTI, RCC, prostate cancer	Female: bladder tumour, UTI, RCC

Table 2. Etiology by Type

Pseudohematuria	Infectious/ Inflammatory	Malignancy	Benign	Structural	Hematologic
Vaginal bleeding Dyes (beets, rhodamine B in candy and juices) Hemoglobin (hemolytic anemia) Myoglobin (rhabdomyolysis) Drugs (rifampin, phenazopyridine, phenytoin) Porphyria Laxatives (phenolphthalein)	Pyelonephritis Cystitis Urethritis Glomerulonephritis Interstitial nephritis Tuberculosis	RCC (mainly adults) Urothelial cancer Wilms' tumour (mainly paediatric) Prostate cancer Leukemia	BPH Polyps Exercise-induced	Stones Trauma Foreign body Urethral stricture Polycystic kidneys Arteriovenous malformation Infarct Hydronephrosis Fistula	Anticoagulants Coagulation defects Sickle cell disease Thromboembolism

History
- timing of hematuria in urinary stream
  - initial: anterior urethra
  - terminal: bladder neck, prostatic urethra
  - total: bladder and above
- presence of blood clots
- LUTS and associated symptoms
  - pyuria, dysuria: UTI
  - flank pain, radiation: ureteral obstruction
- last menstrual period, history of kidney stones, UTI, or previous urologic surgery
  - recent UTI, post-infectious glomerulonephritis, IgA nephropathy
- medications (anticoagulants, rifampin, phenazopyridine, phenytoin)
- risk factors for malignancy (smoking, chemical exposures, Hx of cyclophosphamide therapy, pelvic radiation)

Common Urologic Causes of Hematuria can be Classified as:

TICS
Trauma/Tumour/Toxins
Infection/Inflammatory
Calculi/Cysts
Surgery/Sickle cell and other hematological causes

Investigations
- U/A, urine C&S, urine cytology
- imaging
  - lower tract: cystoscopy
  - upper tract: CT Urogram (gold standard), U/S
- CBC (rule out anemia, leukocytosis), electrolytes, Creatinine (Cr), Blood Urea Nitrogen (BUN), INR, PTT, PSA (in men)

Upper Tract Imaging Options
- **CT Urography (CTU):** Test of choice to evaluate the renal parenchyma and collecting system. Involves exposure to radiation and IV contrast (assess renal function and allergies)
- **U/S:** Superior to IVP for evaluation of renal parenchyma and renal cysts; limited sensitivity for Urothelial carcinoma and small renal masses; U/S alone may be insufficient for upper tract imaging
- **Magnetic Resonance (MR) Urography:** Evaluation of renal parenchyma, collecting system and congenital anomalies; beneficial in paediatric or pregnant patients or when ionizing radiation has to be avoided. (assess renal function and allergies)

Acute Management of Severe Bladder Hemorrhage
- manual irrigation via catheter with normal saline to remove clots
- continuous bladder irrigation (CBI) using large (20-24 Fr) 3-way Foley to help prevent clot formation
  - should be done after manual irrigation of all clots
- cystoscopy
  - identify tumours or other source(s)
  - coagulate obvious sites of bleeding or transurethral resection of tumours (under general or regional anesthesia)

Microscopic Hematuria

Definition
- blood in the urine that is not visible to the naked eye
- >2 RBCs/HPF on urinalysis of at least two separate samples

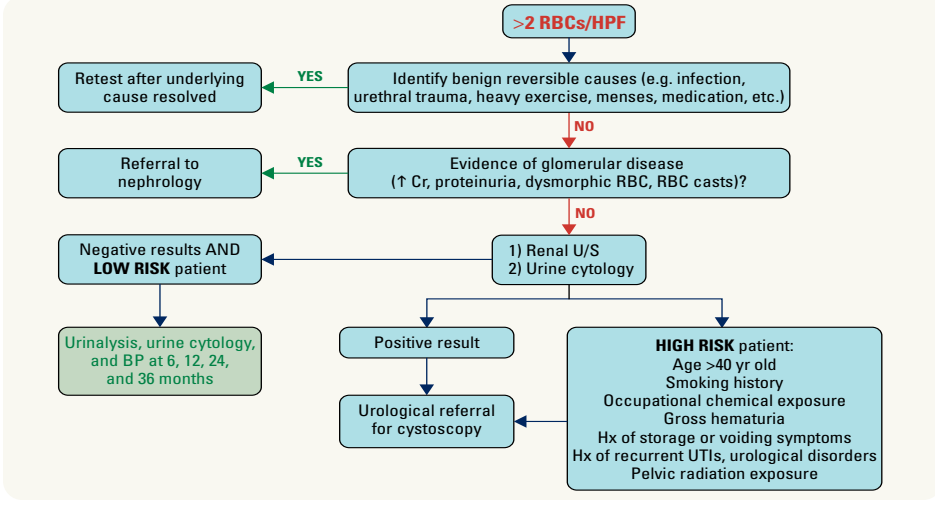

Figure 8. Workup of asymptomatic microscopic hematuria
Based on CUA Guidelines. Alternatively, the AUA recommends cystoscopy and CT urogram for all patients with confirmed microscopic hematuria; follow-up for negative workup is urinalysis yearly for two yr, with repeat anatomic evaluation if microscopic hematuria persists

Lower Urinary Tract Dysfunction

- two phases of lower urinary tract function
  1. storage phase (bladder filling and urine storage) requires:
     - accommodation and compliance
     - no involuntary contraction(s)
  2. voiding phase (bladder emptying) requires:
     - coordinated detrusor contraction
     - synchronous relaxation of outlet sphincters
     - no anatomic obstruction
- lower urinary tract dysfunction can therefore be classified as:
  - failure to store: due to bladder or outlet
  - failure to void: due to bladder or outlet
- three types of symptoms
  - storage (formerly known as irritative)
  - voiding (formerly known as obstructive)
  - post-voiding

Transient Causes of Reversible Urinary Incontinence in the Elderly

DIAPERS
Delirium
Inflammation/Infection
Atrophic vaginitis/urethritis
Pharmaceuticals/**P**sychological
Excess U/O
Restricted mobility/**R**etention
Stool impaction

Urinary Incontinence

Definition
- involuntary leakage of urine

Urgency is the complaint of a sudden compelling desire to void that is difficult to defer; it is not necessarily associated with incontinence

Epidemiology
- variable prevalence in women: 25-45%
- F:M=2:1
- more frequent in the elderly, affecting 5-15% of those living in the community and 50% of nursing home residents

Table 3. Urinary Incontinence: Types and Treatments

Type	Stress	Urgency	Mixed	Overflow
Definition	Leakage with sudden increases in intra-abdominal pressure (cough, sneeze, exertion)	Leakage preceded by strong, sudden urge to void	Leakage with urgency and increased intra-abdominal pressure	Leakage associated with urinary retention
Etiology	Sphincter incompetence Urethral hypermobility Common in middle aged and older women, and men following prostate cancer treatment, or rarely surgical treatment of BPH	Detrusor overactivity Bladder hypersensitivity	Same as stress and urgency incontinence	BPH with overflow incontinence From weak bladder that does not empty (e.g. diabetic cystopathy)
Investigations	Hx: when leakage occurs, number of pads, LUTS, history of neurologic disease, pelvic surgery/radiotherapy, obstetrical history, bowel and sexual function, medications, impact on quality of life P/E: general (edema, neurologic abnormalities, mobility, cognition, dexterity), abdomen (distended bladder), GU (prolapse in women, DRE in men), cough test U/A, urine C&S, voiding diary (type of incontinence, how often, volume of leakage) Urodynamics			See *Urinary Retention*, U7
Management	Risk reduction: weight loss, smoking cessation Kegel exercises pelvic floor muscle therapy (PFMT) Surgery: urethral slings, or artificial sphincter in men	Conservative: fluid management, bladder training, Kegel exercises Medication: anticholinergics, β-3 agonist Botulinum toxin A bladder injection Neuromodulation	Combination of management of stress and urgency incontinence	Catheterization Treat underlying cause

Lower Urinary Tract Symptoms

Urinary Retention

- storage symptoms (FUN): frequency, urgency (strong need to void), nocturia
- voiding symptoms (SHED): stream changes/straining, hesitancy, incomplete emptying, post-void dribbling

Table 4. Etiology of Urinary Retention

Outflow Obstruction	Bladder Innervation	Pharmacologic	Infection
Bladder neck or urethra: calculus, clot, foreign body, neoplasm, neurological (DSD) Prostate: BPH, prostate cancer Urethra: stricture, phimosis, traumatic disruption Miscellaneous: constipation, pelvic mass, severe prolapse in women	Intracranial: CVA, tumour, Parkinson's, cerebral palsy Spinal cord: injury, disc herniation, MS DM Post-abdominal or pelvic surgery	Anticholinergics Narcotics Antihypertensives (ganglionic blockers, methyldopa) OTC cold medications containing ephedrine or pseudoephedrine Antihistamines Psychosomatic substances (e.g. MDMA (ecstasy))	GU: UTI, prostatitis, abscess, genital herpes Infected foreign body Varicella zoster

If a trauma patient is unable to void, has blood at urethral meatus, a scrotal hematoma, or a high riding prostate, there is urethral injury until proven otherwise so catheterization is CONTRAINDICATED unless performed by urology staff or resident

Clinical Features

- suprapubic pain (with acute retention), incomplete emptying, weak stream
- palpable and/or percussible bladder (suprapubic)
- possible purulent/bloody meatal discharge (with UTI)
- increased size of prostate or reduced anal sphincter tone (with neurological disease) on DRE
- neurological: presence of abnormal or absent deep tendon reflexes, reduced "anal wink," saddle anesthesia

Acute vs. Chronic Retention

- **Acute** retention is a medical emergency characterized by suprapubic pain and inability to void
- **Chronic** retention can be painless with greatly increased bladder volume and detrusor hypertrophy followed by atony (late)

Investigations

- CBC, electrolytes, Cr, BUN, U/A and urine C&S, U/S, cystoscopy, urodynamic studies, PVR

Patients with ascites may have a falsely elevated PVR measured by bladder scan

Treatment

- treat underlying cause
- catheterization
  - acute retention
  - immediate catheterization to relieve retention; leave Foley in to drain bladder; follow-up to determine cause; closely monitor fluid status and electrolytes (risk of POD)
  - chronic retention
  - intermittent catheterization by patient may be used; definitive treatment depends on etiology
- suprapubic catheter if obstruction precludes urethral catheter
- for postoperative patients with retention:
  - encourage ambulation
  - α-blockers to relax bladder neck/outlet (men only)
  - may need catheterization
  - definitive treatment will depend on etiology
  - minimize narcotic use

Benign Prostatic Hyperplasia

Definition

- proliferation of epithelial tissue, connective tissue, and smooth muscle in the prostatic transition zone

Etiology

- unknown
  - DHT required (converted from testosterone by 5-α reductase)
  - possible role of impaired apoptosis, estrogens, other growth factors

Epidemiology

- age-related, extremely common (50% of 50 y/o, 80% of 80 y/o)
- 25% of men will require treatment

Clinical Features

- result from outlet obstruction and compensatory and/or age-related changes in detrusor function
- voiding and storage symptoms
- DRE
  - prostate is smooth, rubbery, and may be symmetrically enlarged

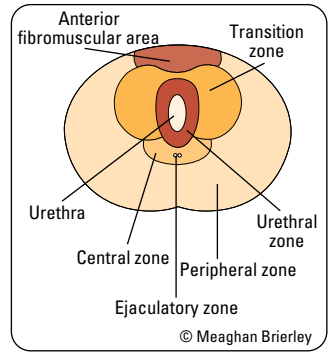

Figure 9. Cross-section of prostate

Prostate size does not correlate well with symptoms in BPH

- complications
  - retention
  - overflow incontinence
  - hydronephrosis
  - renal insufficiency
  - infection
  - gross hematuria
  - bladder stones

Investigations
- mandatory: Hx including LUTS, surgery, trauma, medications (OTC and phytotherapeutic agents), impact of QOL, P/E including DRE, U/A to exclude UTI
- recommended: symptom inventory (IPSS or AUA-Symptom Index (SI)), PSA if >10 yr life expectancy or if it changes management of LUTS
- optional: Cr, urine cytology, uroflowmetry, PVR, voiding diary, sexual function questionnaire
- renal U/S to assess for hydronephrosis
- consider cystoscopy or bladder ultrasound prior to potential surgical management to evaluate outlet and prostate volume
- biopsy if suspicious for malignancy, i.e. elevated PSA or abnormal DRE

Treatment

Table 5. Treatment of BPH (see Table 28, U47, Figure 6, U3, and Figure 7, U4)

	Conservative	Medical	Surgical	Minimally Invasive Surgical Therapies
When to use	Asymptomatic or mildly symptomatic, minimal bother	Moderately to severely symptomatic, bothersome	Absolute or relative indications, significant bother	Patients who wish to avoid or may not tolerate surgery
Options	Watchful waiting: 50% of patients improve spontaneously Lifestyle modifications (e.g. evening fluid restriction, planned voiding)	α-adrenergic antagonists: reduce smooth muscle tone (neck of bladder, prostate, urethra) 5-α reductase inhibitor: block conversion of testosterone to DHT; act to reduce prostate size Combination of α-adrenergic antagonists and 5-α reductase inhibitor is synergistic Antimuscarinics or β-3 agonist (for storage LUTS, without elevated PVR) PDE5 inhibitors (ED and for storage and voiding LUTS) Desmopressin (LUTS with nocturia); risk of hyponatremia in ≥ 65 yr	TURP (see U45) BPKVP (<60 cc) Laser prostatectomy TUIP (<30 cc) Aquablation (<80 cc) Open simple prostatectomy (>100 cc)	TUMT UroLift (<80 cc) Convective water vapour energy ablation (Rezum™) Prostatic stent (for those unfit for surgery)

Approximate Prostate Sizes
20 cc – chestnut
25 cc – plum
50 cc – lemon
75 cc – orange
300 cc – grapefruit

AUA BPH Symptom Score

FUNWISE
Frequency
Urgency
Nocturia
Weak stream
Intermittency
Straining
Emptying, incomplete feeling of

Each symptom graded out of 5
0-7: Mildly symptomatic
8-19: Moderately symptomatic
20-35: Severely symptomatic
Note: dysuria not included in score but is commonly associated with BPH

Initial α-adrenergic antagonist monotherapy for score <20, combination therapy for score >20 (type of medication is size-dependent; 5-α reductase inhibitor beneficial with larger prostates)

Men with planned cataract surgery should avoid starting α-adrenergic antagonists until after their surgery due to the risk of intraoperative floppy iris syndrome

BPH Surgery

Absolute Indication
- Renal failure with obstructive uropathy
- Refractory urinary retention

Relative Indications
- Recurrent UTIs
- Recurrent hematuria refractory to medical treatment
- Renal insufficiency (rule out other causes)
- Bladder stones
- Severe symptoms unresponsive to medical therapies

Urethral Stricture

Definition
- decrease in urethral calibre due to scar formation in urethra
- M>F

Etiology
- congenital
  - failure of normal canalization (e.g. posterior urethral valves)
- trauma
  - instrumentation/catheterization (most common)
  - external trauma (e.g. burns, straddle injury)
  - foreign body
- infection
  - long-term indwelling catheter
  - STI (gonococcal or chlamydial disease)
- inflammation
  - balanitis xerotica obliterans (BXO; lichen sclerosus or chronic progressive sclerosing dermatosis of the male genitalia) causing meatal and urethral stenosis
  - radiation
- malignancy (urothelial carcinoma)
  - most urethral cancers in men are squamous (vs. prostate, bladder, or upper tract that are mostly transitional cell in origin)

Clinical Features
- voiding and storage symptoms +/- gross hematuria
- urinary retention
- hydronephrosis
- related infections: recurrent UTI, secondary prostatitis/epididymitis

Investigations
- laboratory findings
  - flow rates <10 mL/s (normal >15 mL/s) on uroflowmetry
  - urine culture usually negative, but U/A may show pyuria
- radiologic findings
  - RUG and VCUG will demonstrate location
- cystoscopy

Treatment
- urethral dilatation
  - temporarily increases lumen size by breaking up scar tissue
  - healing will often reform scar tissue, recurrence of stricture
- visual internal urethrotomy (VIU)
  - endoscopically incise stricture
  - equal success rates to dilation with mid bulbar strictures <2 cm
  - high rate of recurrence (30-80%), avoid in younger patients
- open surgical reconstruction (urethroplasty)
  - complete stricture excision with anastomosis depending on location and size of stricture
  - may require graft to reconstruct (e.g. buccal mucosa)
  - higher success rate than urethral dilatation or visual internal urethrotomy

Neurogenic Bladder

Definition
- dysfunction of the urinary bladder due to deficiency in some aspect of its innervation, often presents with overflow incontinence and urgency incontinence

Neurophysiology
- see Figure 6, U3 and Figure 7, U4
- stretch receptors in the bladder wall relay information to PMC and activate micturition reflex (normally inhibited by cortical input)
  - micturition (voiding)
  - stimulation of parasympathetic neurons (bladder contraction)
  - inhibition of sympathetic and somatic neurons (internal and external sphincter relaxation, respectively)
  - voluntary relaxation of the pelvic floor and striated urethral sphincter
  - urine storage
  - opposite of micturition
- voluntary action of external sphincter (pudendal nerve roots S2-S4) can inhibit urge to urinate
- cerebellum, basal ganglia, thalamus, and hypothalamus all have input at PMC in the brainstem to inhibit the detrusor reflex

Examples of Neurogenic Lower Urinary Tract Dysfunction
- neurogenic detrusor overactivity (NDO; formerly termed detrusor hyperreflexia)
  - lesion above PMC (e.g. stroke, tumour, MS, Parkinson's disease)
  - loss of voluntary inhibition of voiding
  - intact pathway inferior to PMC maintains coordination of bladder and sphincter
- detrusor sphincter dyssynergia (DSD)
  - suprasacral lesion of spinal cord (e.g. trauma, MS, arteriovenous malformation, transverse myelitis)
  - loss of coordination between detrusor and sphincter (detrusor contracts on closed sphincter and vice versa)
  - component of detrusor overactivity as well
- detrusor atony/areflexia
  - lesion of sacral cord or peripheral nerves (e.g. trauma, DM, disc herniation, MS, congenital spinal cord abnormality, post abdominoperineal resection)
  - flaccid bladder which fails to contract
  - may progress to poorly compliant bladder with high pressures
- peripheral autonomic neuropathy
  - deficient bladder sensation → increasing residual urine → decompensation (e.g. DM, neurosyphilis, herpes zoster)
- muscular lesion
  - can involve detrusor, smooth/striated sphincter

Combination Therapy vs. α-Blocker or 5ARI
BJU Int 2011;107(6):946-54
Purpose: To compare the incidence of acute urinary retention, benign prostatic hyperplasia (BPH)-related surgery and overall clinical progression in patients treated with tamsulosin, dutasteride, and combination therapy.
Methods: 4 yr combination of dutasteride and tamsulosin study was a multicentre double-blind RCT of outcomes in men ≥50 yr with symptomatic BPH, with PSA ≥1.5 ng/mL and ≤10 ng/mL, and prostate volume ≤30 mL. Patients received tamsulosin, dutasteride or combination therapy. Primary endpoint was time to first acute urinary retention or BPH-related surgery; secondary endpoint was clinical progression of BPH/symptoms.
Results: Combination therapy resulted in significantly greater improvements in symptoms compared to dutasteride from 3 mo, and tamsulosin from 9 mo, and in BPH-related health status from 3 and 12 mo, respectively. There was a significant increase in Adverse Drug Events (ADE) with combination therapy vs. monotherapies. However, withdrawal rates due to drug-related adverse events were similar across the treatment groups.
Conclusions: Men with baseline prostate volume ≥40 mL and baseline PSA ≥1.5 ng/mL had greater reductions in relative risk (RR) of BPH-related surgery and RR of clinical progression on combined therapy or dutasteride monotherapy than on tamsulosin monotherapy.

Finasteride for Benign Prostatic Hyperplasia
Cochrane DB Syst Rev 2010;10:CD006015
Purpose: To examine the effectiveness and safety of finasteride vs. placebo or other active controls for the treatment of urinary tract symptoms.
Summary of Findings:
1. Finasteride improved urinary symptoms more than placebo in trials >1 yr duration and significantly lowered the risk of BPH progression.
2. Compared with α-blockers, finasteride was less effective than either doxazosin or terazosin, but equally as effective as tamsulosin.
3. Symptom improvement with finasteride + doxazosin is equal to doxazosin alone.
4. Finasteride treatment resulted in an increased risk of ejaculation disorder, impotence, and lowered libido compared with placebo.
5. Compared with doxazosin and terazosin, finasteride had a lower risk of asthenia, dizziness, and postural hypotension.

Nerve roots in micturition:
"S2-3-4 keeps the urine off the floor"

Neuro-Urologic Evaluation

"Spinal shock" initially manifests as atonic bladder

- Hx and P/E (urologic and general neurologic)
- voiding diary, assess for incontinence, urinary symptoms, and UTI risk (hydration status, catheterization, voiding frequency)
- catheterization volumes in patients with CIC
- all patients: U/A, PVR, renal profile
  - moderate/high-risk (SCI, spina bifida, MS): urodynamics, renal U/S, renal profile
- imaging
  - U/S to rule out hydronephrosis and stones; occasionally CT scanning with or without contrast
- cystoscopy (if suspicion of bladder tumour, hematuria)
- urodynamic studies
  - uroflowmetry to assess flow rate, pattern
  - filling CMG to assess capacity, compliance, detrusor overactivity
  - voiding CMG (pressure-flow study) to assess bladder contractility and extent of bladder outflow obstruction
  - video study to visualize bladder/bladder neck/urethra during CMG using x-ray contrast
  - EMG and video ascertains presence of coordinated or uncoordinated voiding, allows accurate diagnosis of DSD

Treatment

- goals of treatment
  - prevent renal deterioration
  - prevent infections (UTI)
  - achieve social continence
- clean intermittent catheterization (CIC) (if there is associated inability to void)
- treatment options depend on status of bladder and urethra
  - bladder hyperactivity → antimuscarinic medications to relax bladder (see *Urinary Incontinence*, U6)
    - if refractory
      - botulinum toxin injections into bladder wall (detrusor muscle)
      - occasionally augmentation cystoplasty (enlarging bladder volume and improving compliance by grafting section of detubularized bowel onto the bladder)
      - occasionally urinary diversion (ileal conduit or continent diversion) in severe cases if bladder management unsuccessful
  - flaccid bladder → CIC

Dysuria

Definition

- painful urination

Etiology

Table 6. Differential Diagnosis of Dysuria

Infectious	Cystitis, urethritis, prostatitis, epididymitis/orchitis (if associated with lower tract inflammation), cervicitis, vulvovaginitis, perineal inflammation/infection, tuberculosis, vestibulitis
Neoplasm	Kidney, bladder, prostate, penis, vagina/vulva, BPH
Calculi	Bladder stone, urethral stone, ureteral stone
Inflammatory	Seronegative arthropathies (reactive arthritis: arthritis, uveitis, urethritis), drug side effects, autoimmune disorders, chronic pelvic pain syndrome (CPPS), interstitial cystitis
Hormonal	Endometriosis, hypoestrogenism
Trauma	Catheter insertion, post-coital cystitis (honeymoon cystitis)
Psychogenic	Somatization disorder, depression, stress/anxiety disorder
Other	Contact sensitivity, foreign body, radiation/chemical cystitis, diverticulum

Investigations

- focused Hx and P/E to determine cause (fever, d/c, conjunctivitis, CVA tenderness, back/joint pain)
  - any d/c (urethral, vaginal, cervical) should be sent for gonococcus/chlamydia testing; wet mount if vaginal d/c
  - U/A and urine C&S
  - if suspect infection, may start empiric ABx treatment (see Table 9, U16)
  - ± imaging of urinary tract (tumour, stones)

Hydronephrosis

Definition
- the upper urinary tract consists of the kidneys and ureters
- dilation of the renal pelvis, calyces, and ureters, generally caused by obstruction of antegrade urine flow (i.e. pelvicaliectasis)

Etiology
- mechanical
  - congenital: see *Congenital Abnormalities*, U39
  - acquired
    - intrinsic: trauma, inflammation and bleeding, calculi, urologic neoplasms, BPH, urethral stricture, phimosis, previous urological surgery
    - extrinsic: trauma, neoplasms (uterine fibroid; colorectal, uterine, and cervical malignancies; lymphoma), aortic aneurysm, pregnancy (gravid uterus)
- functional
  - neuropathic: neurogenic bladder, diabetic neuropathy, spinal cord disease
  - hormonal: pregnancy (progesterone decreases ureteral tone)

Investigations
- focused Hx, inquiring about pain (flank, lower abdomen, testes, labia), U/O, medication use, pregnancy, trauma, fever, Hx of UTIs, calculi, PID, and urological surgery
- CBC, electrolytes, Cr, BUN, U/A, urine C&S
- imaging studies (U/S is >90% sensitive and specific)
  - CT: helps delineate anatomy and potential causes (e.g. obstructing stone), but does not provide much functional information
  - mercaptoacetyltriglycine (MAG3) diuretic renogram: provides little anatomic structural information but evaluates differential renal function and demonstrates if functional obstruction exists
  - retrograde pyelogram: helps to delineate anatomy and can allow for stent insertion to decompress if obstruction is present

Treatment
- hydronephrosis can be physiologic (e.g. pregnancy)
- treatment should be guided at improving symptoms, treating infections, or improving renal function
- urgent treatment may require percutaneous nephrostomy tube or ureteral stenting to relieve pressure
- treatment can include pyeloplasty to repair an obstructed UPJ in congenital or acquired UPJ obstruction

Post-Obstructive Diuresis

Definition
- polyuria resulting from relief of obstructive uropathy (i.e. elevated creatinine)
- >3 L/24 h or >200 cc/h for two consecutive hours

Pathophysiology
- physiologic POD secondary to excretion of retained urea, Na^+, and H_2O (high osmotic load) after relief of obstruction
  - self-limiting; usually resolves in 48 h with PO fluids but may persist to pathologic POD
- pathologic POD is a Na^+-wasting nephropathy secondary to impaired concentrating ability of the renal tubules due to:
  - decreased reabsorption of NaCl in the thick ascending limb and urea in the collecting tubule
  - increased medullary blood flow (solute washout)
  - increased flow and solute concentration in the distal nephrons

Management
- admit patient and closely monitor hemodynamic status and electrolytes (Na^+ and K^+ q6-12 h and replace prn; follow Cr and BUN to baseline)
- monitor U/O q2 h and ensure total fluid intake <U/O by replacing every 1 mL U/O with 0.5 mL 1/2 normal saline (NS) IV (PO fluids if physiologic POD)
- avoid glucose-containing fluid replacement (iatrogenic diuresis)

Overactive Bladder

Definition
- a symptom complex that includes urinary urgency with or without incontinence, urinary frequency (voiding ≥8 times in a 24 h period), and nocturia (awakening ONE or more times at night to void)

Etiology
- multiple etiologies proposed (neurogenic, myogenic, idiopathic)
- symptoms thought to be from involuntary contractions of the detrusor muscle
- may be associated with other conditions such as SUI in women and BPH in men (see Table 5, U8)

Epidemiology
- F:M=1:1
- prevalence increases with age. 42% in males ≥75 y/o; 31% in females ≥75 y/o
- women experience incontinence more commonly than men

Diagnosis
- the diagnostic process should document symptoms that define overactive bladder and exclude other disorders that could cause the patient's symptoms
- minimal requirements for the process consist of:
  - focused history including past genitourinary disorders and conditions outlined in Table 7, questionnaires of LUTS and diaries of urination frequency, volume and pattern (3 d micturition diary)
  - P/E including genitourinary, pelvic and rectal examination
  - U/A to rule out hematuria and infection
- in some patients, the following investigations could be considered
  - post-void residual
  - cystoscopy to rule out recurrent infections, carcinoma *in situ* and other intravesical abnormalities
- urodynamics to rule out obstruction in older men

Treatment
- non-pharmacological: behaviour therapies such as bladder training, bladder control strategies, pelvic floor muscle training, fluid management, weight reduction (if overweight), and avoidance of caffeine and alcohol
- pharmacological (see Table 29, U48)
  - antimuscarinics: oxybutynin hydrochloride, tolterodine, solifenacin, fesoterodine, darifenacin, propiverine, or trospium
  - β3-adrenoceptor agonist: mirabegron
- refractory patients may be treated with:
  - neuromuscular-junction inhibition: botulinum toxin bladder injection
- others
  - percutaneous tibial nerve stimulation (not used commonly in Canada)
  - sacral neuromodulation

Table 7. Conditions that Could Contribute to Symptoms of Overactive Bladder

Lower Urinary Tract Conditions	UTI, obstruction, impaired bladder contractility
Neurological Conditions	Stroke, MS, dementia, diabetic neuropathy
Systemic Diseases	CHF, sleep disorders (primarily nocturia)
Functional and Behavioural	Excessive caffeine and alcohol, constipation, impaired mobility
Medication	Diuretics, anticholinergic agents, narcotics, calcium-channel blocker, cholinesterase inhibitors

Infectious and Inflammatory Diseases

Table 8. Antibiotic Treatment of Urological Infections

Condition	Drug	Duration
Urethritis	**Non-Gonococcal**	
	azithromycin (1 g PO)	x 1 d
	OR	
	doxycycline (100 mg PO BID)	7 d
	Gonococcal	
	ceftriaxone (250 mg IM) AND treat for *Chlamydia trachomatis*	x 1
Simple, Uncomplicated UTI	TMP/SMX (160 mg/800 mg PO BID)	3 d
	OR	
	nitrofurantoin (100 mg PO BID)	5 d
Complicated UTI	ciprofloxacin (1 g PO once daily OR 400 mg IV q12 h)	up to 2-3 wk
	OR	
	ampicillin (1 g IV q6 h) + gentamicin (1 mg/kg IV q8 h) (used for relatively short courses because of toxicity)	up to 2-3 wk
	OR	
	ceftriaxone (1-2 g IV q24 h)	up to 2-3 wk
Recurrent/Chronic Cystitis	Prophylactic Treatment	
	Continuous: TMP-SMX (40 mg/200 mg PO QHS OR 3x/wk)	6-12 mo
	OR	
	nitrofurantoin (50-100 mg PO QHS)	6-12 mo
	Post-Coital: TMP-SMX (40 mg/200 mg-80 mg/400 mg)	within 2 h of coitus
	OR	
	nitrofurantoin (50-100 mg PO once daily)	within 2 h of coitus
Acute Prostatitis	ciprofloxacin (500-750 mg PO BID)	2-4 wk
	OR	
	TMP-SMX (160 mg/800 mg PO BID)	4 wk
	OR	
	IV therapy with gentamicin and ampicillin, penicillin with β-lactamase inhibitor, 3rd gen cephalosporin, OR a fluoroquinolone	4 wk (IV and oral step-down)
Chronic Prostatitis	ciprofloxacin (500 mg PO BID)	4-6 wk
	± α-blockers, anti-inflammatories	
Epididymitis/Orchitis	<35 yr (presumed STI) ceftriaxone (200 mg IM)	x 1
	AND	
	doxycycline (100 mg PO BID)	10 d
	≥35 yr (presumed urinary source)	
	ofloxacin (300 mg PO BID)	10 d
Acute Uncomplicated Pyelonephritis	ciprofloxacin (500 mg PO BID)	7 d
	± ceftriaxone (1 g IV) OR ciprofloxacin (400 mg IV)	x 1
	OR	
	IV therapy with a fluoroquinolone, gentamicin and ampicillin, extended spectrum cephalosporin, extended spectrum penicillin, OR a carbapenem	14 d total IV and oral step-down

Antibiotic therapy should always be based on local resistance patterns and adjusted according to culture and sensitivity results

Acute uncomplicated pyelonephritis: suspected or confirmed *Enterococcus* infection requires treatment with ampicillin

Urinary Tract Infection

- for UTIs during pregnancy, see Obstetrics, OB31

Definition

- symptoms suggestive of UTI + evidence of pyuria and bacteriuria on U/A or urine C&S
  - if asymptomatic + 100000 CFU/mL = asymptomatic bacteriuria; only requires treatment in certain patients (e.g. pregnancy, immunosuppressed, prior to urologic surgery)

Classification

- uncomplicated: lower UTI in a setting of functionally and structurally normal urinary tract
- complicated: structural and/or functional abnormality, male patients, immunocompromised, diabetic, iatrogenic complication, pregnancy, pyelonephritis, catheter-associated
- recurrent: see *Recurrent/Chronic Cystitis*, U14

Risk Factors

- stasis and obstruction
  - residual urine due to impaired urine flow (e.g. PUVs, reflux, medication, BPH, urethral stricture, cystocele, neurogenic bladder)
- foreign body
  - introduce pathogen or act as nidus of infection (e.g. catheter, instrumentation)
- decreased resistance to organisms
  - DM, malignancy, immunosuppression, spermicide use, estrogen depletion, antimicrobial use
- other factors
  - trauma, anatomic abnormalities, female, sexual activity, menopause, fecal incontinence

Clinical Features
- storage symptoms: frequency, urgency
- voiding symptoms: hesitancy, post-void dribbling, dysuria
- other: suprapubic pain, hematuria, foul-smelling urine
- pyelonephritis – if present: typically presents with more severe symptoms (e.g. fever/chills, CVA tenderness, flank pain)

Indications for Investigations
- pyelonephritis
- persistence of pyuria/symptoms following adequate antibiotic therapy
- severe infection with an increase in Cr
- recurrent/persistent infections
- atypical pathogens (urea splitting organisms)
- Hx of structural abnormalities/decreased flow

Investigations
- U/A, urine C&S (only if symptomatic)
  - U/A: leukocytes ± nitrites ± hematuria
  - C&S: midstream, catheterized, or suprapubic aspirate
- if hematuria present, retest post-treatment, if persistent need hematuria workup (see *Microscopic Hematuria*, U5)
- U/S, CT scan if recurrent or treatment-resistant UTIs, suspected anatomic abnormalities, history indicates complicated cystitis
- pelvic examination for women if recurrent UTI

Treatment
- see Table 8, *Antibiotic Treatment of Urological Infections*, U13
- asymptomatic bacteriuria should not be treated (exceptions: pregnancy, before urological procedure)
- if febrile, consider admission with IV therapy and rule out obstruction

Prevention of UTIs
- maintain good hydration (emerging evidence re: cranberry preparations and D-mannose)
- void regularly (do not hold urine for prolonged periods of time)
- avoid feminine hygiene sprays and scented douches
- empty bladder immediately before and after intercourse

Organisms
- typical organisms: SEEK PP (*E. coli* 75-95%)
- atypical organisms
  - tuberculosis (TB)
  - *Chlamydia trachomatis*
  - *Mycoplasma* (*Ureaplasma urealyticum*)
  - fungi (*Candida*)

Prevention of UTIs
- Maintain good hydration (try cranberry preparations or D-mannose)
- Avoid feminine hygiene sprays and scented douches
- Empty bladder immediately before and after intercourse
- Vaginal estrogen therapy for peri- and post-menopausal women with recurrent UTIs

Recurrent/Chronic Cystitis

Definition
- ≥3 UTIs/yr

Etiology
- bacterial reinfection (80%) vs. bacterial persistence (relapse)
  - bacterial reinfection
    - recurrence of infection with either 1) a different organism, 2) the same organism if cultured >2 wk following therapy, or 3) with any organism with an intermittent sterile culture
  - bacterial persistence
    - same organism cultured within 2 wk of sensitivity-based therapy

Investigations
- assess predisposing factors
- investigations may include cystoscopy, U/S, CT

Treatment
- lifestyle changes (limit caffeine intake, increase fluid/H_2O intake)
- ABx (various strategies): continuous low-dose daily suppression vs. post-coital only vs. self-start therapy
- post-menopausal women: consider topical estrogen therapy
- no treatment for asymptomatic bacteriuria except in pregnant women or patients undergoing urinary tract instrumentation

Interstitial Cystitis (Painful Bladder or Bladder Pain Syndrome)

Definition
- bladder pain, chronic urgency, and frequency without other identifiable causation

Classification
- non-ulcerative (more common) and ulcerative (Hunner's lesions)

Etiology
- unknown

Epidemiology
- prevalence: 20 in 100000
- 90% of cases are in females, 94% are white
- median age is 40 yr (non-ulcerative seen in younger to middle-aged, while ulcerative seen in middle-aged to older)

Clinical Features
- pelvic pain (typically supra-pubic tenderness)
- storage symptoms (frequency > urgency > nocturia)
- negative U/A, urine C&S, urine cytology
- cystoscopy: glomerulations (submucosal petechiae), Hunner's lesions

Cystoscopic evaluation is not necessary to make a diagnosis

Differential Diagnosis
- urology: non-infectious cystitis (radiation, chemical, eosinophilic, TB), OAB, bladder calculi, prostate-related pain
- gynaecology: endometriosis, vulvar disorders
- neurology: pudendal nerve entrapment
- MSK: pelvic floor disorders
- drugs: ketamine, tiaprofenic acid

Investigations
- Hx, P/E, frequency volume chart
- symptom scores to establish baseline and response to treatment
- U/A, urine C&S, urine cytology
- cystoscopy

Treatment
- first line: patient education, dietary modifications, bladder retraining, stress management
  - pelvic floor physiotherapy can be added for patients with pelvic floor dysfunction or pelvic pain
- second line: guided by symptom phenotype
  - oral: amitriptyline, cimetidine, hydroxyzine, pentosan polysulfate (PPS), gabapentin, quercetin
  - intravesical: dimethylsulfoxide, heparin, lidocaine, PPS, oxybutynin
- third line: hydrodistension, botulinum toxin A, sacral neuromodulation
  - endoscopic treatment if Hunner's lesions (cauterization, resection, triamcinolone injection)
- fourth line: radical surgery (substitution cystoplasty or urinary diversion ± cystectomy)

Acute Pyelonephritis

Definition
- infection of the renal parenchyma with local and systemic manifestations
- clinical diagnosis of flank pain, fever, and elevated WBC

Etiology
- ascending from lower UTI (usually Gram-negative bacilli) or hematogenous route (usually Gram-positive cocci)
- causative microorganisms
  - Gram positives: *Enterococcus faecalis, S. aureus, S. saphrophyticus*
  - Gram negatives: *E. coli, Klebsiella, Proteus, Pseudomonas, Enterobacter*
- common underlying causes of pyelonephritis
  - stones, strictures, prostatic obstruction, vesicoureteric reflux, neurogenic bladder, catheters, DM, sickle-cell disease, PCKD, immunosuppression, post-renal transplant, instrumentation, pregnancy

Clinical Features
- rapid onset (<24 h)
- LUTS including frequency, urgency, hematuria; NOT dysuria unless concurrent cystitis
- fever, chills, nausea, vomiting, myalgia, malaise
- CVA tenderness and/or exquisite flank pain

Investigations
- U/A, urine C&S
- CBC and differential: leukocytosis, left shift
- imaging if complicated pyelonephritis or symptoms do not improve with 48-72 h of treatment
  - abdominal/pelvic U/S
  - CT
- nuclear medicine: DMSA scan can be used to help secure the diagnosis
  - a photopenic defect indicates active infection or scar; if normal alternative diagnoses should be considered

Treatment
- hemodynamically stable
  - outpatient oral ABx treatment ± single initial IV dose (see Table 8, U13)
- severe or non-resolving
  - admit, hydrate, and treat with IV ABx (see Table 8, U13)
- emphysematous pyelonephritis
  - most patients receive nephrectomy after IV ABx started and patient stabilized
  - consider temporization with nephrostomy tubes
- renal obstruction
  - admit for emergent stenting or percutaneous nephrostomy tube

Prostatitis/Prostatodynia

Epidemiology
- prevalence: 9% of men/yr, 6% with bothersome symptoms
- most common urologic diagnosis in men <50 y/o, 3rd most common in men >50 y/o

Classification

Table 9. Comparison of the Four Types of Prostatitis

	Acute Bacterial Prostatitis (Category I)	Chronic Bacterial Prostatitis (Category II)	Chronic Pelvic Pain Syndrome (Category III)	Asymptomatic Prostatitis (Category IV)
Etiology	Acute infection SEEK PP (80% *E. coli*)	Chronic infection ± prostatitis symptoms	Symptoms without evidence of infection IIIA: inflammatory IIIB: non-inflammatory	Incidental inflammation
Clinical Features	LUTS, pelvic pain Systemic signs: fever, chills, malaise Leukocytosis in prostatic fluid Positive bacterial cultures	LUTS, pelvic pain No systemic signs Recurrent UTIs Leukocytosis in prostatic fluid Positive bacterial cultures	LUTS, pelvic pain IIIA: leukocytosis in prostatic fluid IIIB: no leukocytosis in prostatic fluid	No symptoms Leukocytosis in prostatic fluid
Investigations	Hx, P/E (abdominal, external genitalia, perineum, prostate) U/A, urine C&S TRUS if suspect abscess	Hx, P/E (same as Category I + pelvic floor) 4 glass test for culture: VB1 (urethra) VB2 (bladder) EPS (post-massage) VB3 (post-massage)	Hx, P/E (same as Category II) Symptom score (NIH-CPSI*) 4-glass test Consider psychological assessment	No investigations unless considering ABx for elevated PSA or infertility
Treatment	ABx (see Table 8, U13) Catheterization if severe obstructive Drainage if abscess is present	ABx (see Table 8, U13) α-blocker if obstruction	Supportive measures ABx if ABx naïve Multimodal therapy (UPOINT), including: α-blockers Anti-inflammatories Phytotherapy (quercetin, cernilton)	ABx if elevated PSA, infertility, or planned prostate biopsy

*NIH-CPSI: National Institute of Health Chronic Prostatitis Symptom Index

Epididymitis and Orchitis

Etiology
- common infectious causes
  - <35 yr: *Neisseria gonorrhoeae* or *Chlamydia trachomatis*
  - ≥35 yr or penetrative anal intercourse: GI organisms (especially *E. coli*)
- other causes
  - mumps infection may involve orchitis, post-parotitis
  - TB
  - syphilis
  - granulomatous (autoimmune) in elderly men
  - amiodarone (involves only head of epididymis)
  - chemical: reflux of urine into ejaculatory ducts

Risk Factors
- UTI
- unprotected sexual contact
- instrumentation/catheterization
- increased pressure in prostatic urethra (straining, voiding, heavy lifting) may cause reflux of urine along vas deferens ➔ sterile epididymitis
- immunocompromised

Clinical Features
- sudden onset scrotal pain and swelling ± radiation along cord to flank
- scrotal erythema and tenderness
- Prehn's Sign (relief of pain with lifting of testicle)
- fever
- storage symptoms, purulent d/c
- reactive hydrocele

Investigations
- U/A, urine C&S
- ± urethral d/c: Gram stain/culture
- if diagnosis uncertain, MUST rule out testicular torsion (U/S Doppler)
- U/S can confirm diagnosis with increased vascularity

Treatment
- rule out torsion (see Table 23, *Investigations*, U32)
- see Table 8, U13 for ABx therapy
- scrotal support, bed rest, ice, analgesia

Complications
- if severe ➔ testicular atrophy
- 30% have persistent infertility problems
- inadequately treated acute epididymitis may lead to chronic epididymitis or epididymo-orchitis

If unsure between diagnoses of epididymitis and torsion, always go to OR
Remember: torsion >6 h has poor prognosis

Urethritis

Etiology
- infectious or inflammatory (e.g. reactive arthritis)

Table 10. Infectious Urethritis: Gonococcal vs. Non-Gonococcal

	Gonococcal	Non-Gonococcal
Causative Organism	*Neisseria gonorrhoeae*	Usually *Chlamydia trachomatis*
Diagnosis	Hx of sexual contact, thick, profuse, yellow-grey purulent d/c, LUTS Gram stain (GN diplococci), urine PCR and/or culture from urethral specimen	Hx of sexual contact, mucoid whitish purulent d/c, ± storage LUTS Gram stain demonstrates >4 PMN/oil immersion field, no evidence of *N. gonorrhoeae*, urine PCR and/or culture from urethral specimen
Treatment	See Table 8, U13	See Table 8, U13

Reactive Arthritis (formerly known as Reiter's syndrome)
Urethritis, uveitis (or conjunctivitis), and arthritis
(can't pee, can't see, can't climb a tree)

If culture negative or unresponsive to treatment consider: *Ureaplasma urealyticum, Mycoplasma genitalium, Trichimonas vaginalis*, HSV, or adenovirus

Stone Disease

Epidemiology
- prevalence: ~8% and increasing
- M:F=2:1
- peak incidence 30-50 yr of age
- recurrence rate: 10% at 1 yr, 50% at 5 yr, 60-80% lifetime
- calcium oxalate most common stone type; others include uric acid, struvite, calcium phosphate, cystine, etc.

Risk Factors
- **hereditary**: RTA, Glucose-6-phosphate dehydrogenase deficiency, cystinuria (defect in the proximal renal tubular reabsorption of cystine), COLA syndrome (defect in resorption of cystine, ornithine, lysine and arginine), xanthinuria, hyperoxaluria, etc.
- **lifestyle**: minimal fluid intake (most common risk factor); excess vitamin C, oxalate, purines, calcium; living or working in extreme heat
- **medications**: loop diuretics (furosemide, bumetanide), acetazolamide, topiramate, zonisamide, indinavir, acyclovir, sulfadiazine, triamterene
- **medical conditions**: UTI (with urea-splitting organisms: *Proteus, Pseudomonas, Providencia, Klebsiella, Mycoplasma, Serratia, S. aureus*), myeloproliferative disorders, inflammatory bowel disease, gout, DM, hypercalcemia disorders (hyperparathyroidism, tumour lysis syndrome, sarcoidosis, histoplasmosis), obesity (BMI >30)
- **bladder stones**: bladder outlet obstruction, catheters, neurologic disease, DM (requires different management)

Key Points in Stone Hx
- Diet (especially FLUID INTAKE)
- Predisposing medical conditions
- Predisposing medications
- Previous episodes/investigations/ treatments
- FMHx (1st degree relative)

Clinical Features
- urinary obstruction ➔ upstream distention ➔ pain
  - flank pain from renal capsular distention (non-colicky)
  - severe waxing and waning pain that can radiate from flank to groin, testis, or tip of penis from distended collecting system or ureter (ureteral colic)
- writhing, persistent discomfort, nausea, vomiting, hematuria (90% microscopic), diaphoresis, tachycardia, tachypnea
- occasionally symptoms of trigonal irritation (frequency, urgency), if the stone is in the lower ureter
- bladder stones result in: storage and voiding LUTS, terminal hematuria, suprapubic pain
- if fever, rule out concurrent pyelonephritis and/or obstruction
- can also present incidentally, without any pain or symptoms

The Four Narrowest Passage Points for Upper Tract Stones
- UPJ
- Pelvic brim
- Under vas deferens/broad ligament
- UVJ

Table 11. Differential Diagnosis of Renal Colic

GU	Abdominal	Neurological
Pyelonephritis Ureteral obstruction from other cause: UPJ obstruction, clot colic secondary to gross hematuria, sloughed papillae Gynaecological: ectopic pregnancy, torsion/ rupture of ovarian cyst, PID	Abdominal aortic aneurysm (AAA) Bowel ischemia Pancreatitis Other acute abdominal crisis (appendicitis, cholecystitis, diverticulitis)	Radiculitis (L1): herpes zoster, nerve root compression Neuromuscular (MSK) back pain

Location of Stones
- calyx: may cause flank discomfort, persistent infection, persistent hematuria, but if non-obstructive, likely remains asymptomatic
- pelvis: tend to cause obstruction at UPJ, may cause persistent infection
- ureter: <5 mm diameter will pass spontaneously in 75% of patients but can do so with varying degrees of pain

	Radiopaque	Radiolucent
KUB	Calcium	Uric acid
	Struvite	Indinavir
	Cystine	Atazanavir
CT	Calcium	Indinavir
	Struvite	Atazanavir
	Cystine	
	Uric acid	

Stone Pathogenesis
- supersaturation of stone constituents (at appropriate temperature and pH)
- stasis, low flow, and low volume of urine (dehydration)
- crystal formation and stone nidus
- loss of inhibitory factors
  - citrate (forms soluble complex with calcium)
  - magnesium (forms soluble complex with oxalate)
  - pyrophosphate
  - Tamm-Horsfall glycoprotein

Approach to Renal Stones

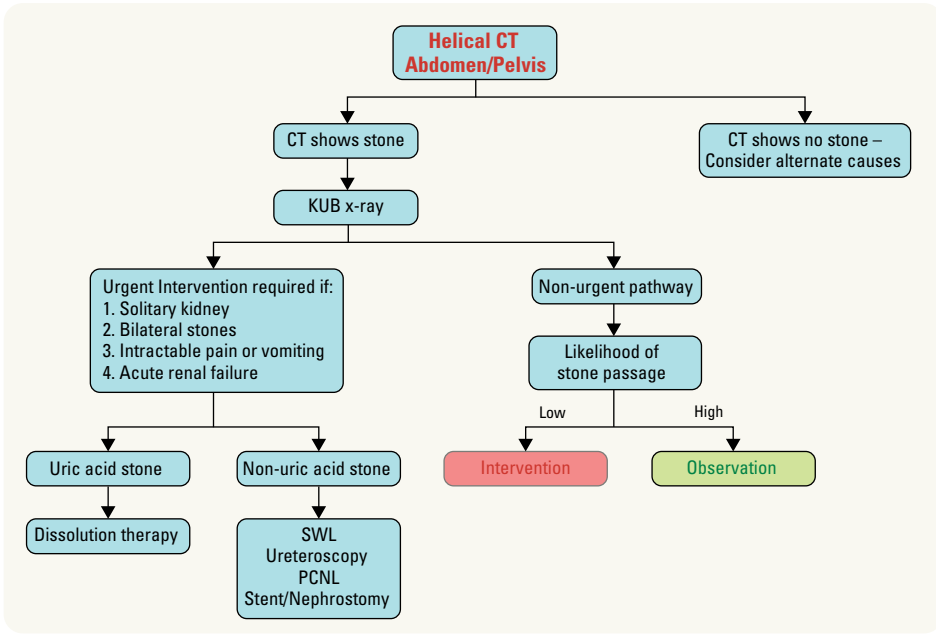

Figure 10. Approach to renal stones

Although hypercalciuria is a risk factor for stone formation, decreasing dietary calcium is NOT recommended to prevent stone formation. Low dietary calcium leads to increased GI oxalate absorption and higher urine levels of calcium oxalate

Stones and Infection
If septic, urgent decompression via ureteric stent or percutaneous nephrostomy is indicated. Definitive treatment of the stone should be delayed until the sepsis has cleared

Indications for PCNL
Size >2 cm
- Staghorn
- UPJ obstruction with correction of obstruction
- Calyceal diverticulum
- Large cystine stones (poorly fragmented with SWL)
- Anatomical abnormalities preventing retrograde access
- Failure of less invasive modalities

Investigations

Table 12. Investigations for Renal Stones

	CBC, U/A, Urine C&S	KUB x-ray	CT Scan (non-contrast)	Abdominal Ultrasound	Cystoscopy	Uric Acid	PTH, 24 h urine x 2 for volume, Cr, Ca^{2+}, Na^{+}, PO_4^{3-}, Mg^{2+}, oxalate, citrate, ± cystine
Who gets it?	Everyone	Most	First episode renal colic	Paediatric cases, pregnant patients, recurrent stone formers, unsure of Dx	± Those concerning for bladder stone	Stone not seen on KUB	Recurrent Ca^{2+} stone formers ± paediatric cases
Why is it done?	May show signs of infection, ± sensitivities	90% of stones are radiopaque Good for follow-up Helps rule out uric acid stones (not visible on x-ray)	Able to see adjacent organs, exact location of stone(s), plan for surgery, etc. Can assess density of stone Gold standard diagnostic test	Identify and follow up stone without radiation exposure Visualize hydronephrosis	Visualize bladder Can provide access to ureter for stent placement if needed	Suspected uric acid stone (urine PH <5.5 might suggest uric acid stone)	Need to rule out metabolic cause for stones
Cautions	Presence of leukocytes NOT always indicative of infection	Not all stones visible on x-ray Do not mistake phleboliths for stones!	Radiation (especially if female of child bearing age) Must be a non-contrast scan	—	—	—	—

Treatment

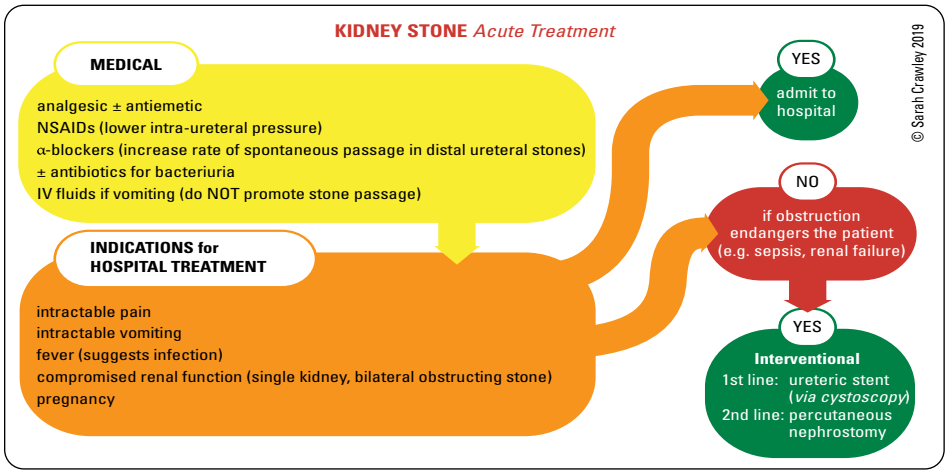

Figure 11. Acute treatment of kidney stone

24 h urine collections must be done AFTER discontinuing stone preventing/promoting medications

Detailed metabolic studies are NOT recommended unless complex patient (recurrent stone formers, pregnancy, paediatric patients, strong FMHx, underlying kidney or systemic disease, rare stone types, etc.)

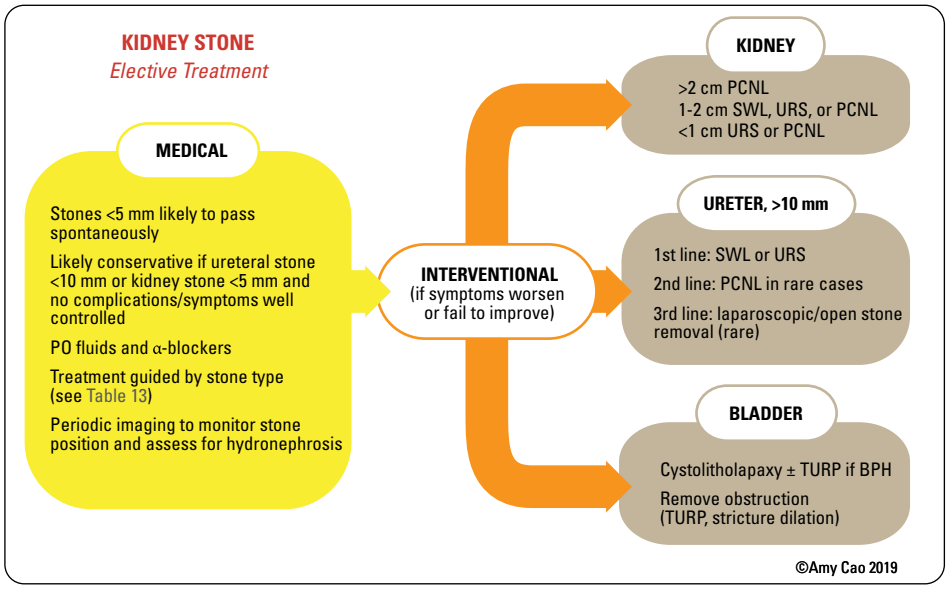

Figure 12. Elective treatment of kidney stone

Prevention

- dietary modification
  - increase fluid (>2 L/d), citrate intake (lemon juice, orange juice)
  - reduce animal protein, oxalate, Na^+, sucrose, and fructose intake
  - avoid high-dose vitamin C supplements
- medications
  - thiazide diuretics for hypercalciuria
  - allopurinol for hyperuricosuria
  - potassium citrate for hypocitraturia, hyperuricosuria

α-Blockers as Medical Expulsive Therapy for Ureteral Stones
Cochrane DB Syst Rev 2018;4:CD008509
Purpose: To assess effects of α-blockers compared with standard therapy for ureteral stones 1 cm or smaller in adult patients presenting with symptoms of ureteral stone disease.
Methods: meta-analysis of 67 RCTs for ureteral stone passage in 10509 adult patients.
Results: Treatment with an α-blocker resulted in increased stone clearance (RR 1.45, 95% CI:1.36-1.55, low quality evidence). Subgroup analyses suggest that α-blockers may be less effective for smaller stones (≤5 mm).
Conclusions: α-blockers likely increase stone clearance, but also slightly increase the risk of major adverse events.

Main Elective Treatment Options
1. Conservative medical management
2. Extracorporeal shockwave lithotripsy (SWL): less invasive (sedation only, no internal instrumentation), less successful
3. Ureteroscopic (URS) laser lithotripsy: slightly more invasive (usually GA or spinal, instrumentation required, usually outpatient), more successful
4. Percutaneous n.phrolithotomy (PCNL): more invasive (requires GA, involves puncture of kidney, often needs admission), most successful for larger stones
5. Laparoscopic or open surgery: rare in modern era unless performing other concomitant procedure (e.g. UPJ obstruction correction)

Table 13. Stone Classification

Type of Stone	Calcium (75-85%)	Uric Acid (5-10%)	Struvite (5-10%)	Cystine (1%)
Etiology	Hypercalciuria Hyperuricosuria (25% of patients with Ca^{2+} stones) Hyperoxaluria (<5% of patients) Hypocitraturia (12% of patients) Other causes: Hypomagnesemia – associated with hyperoxaluria and hypocitraturia High dietary Na^+ Decreased urinary proteins High urinary pH, low urine volume (e.g. GI water loss) Hyperparathyroidism, obesity, gout, DM	Uric acid precipitates in low volume, acidic urine with a high uric acid concentration: Hyperuricosuria alone Drugs (ASA, thiazides) Diet (purine-rich red meats) Hyperuricosuria with hyperuricemia Gout High rate of cell turnover or cell death (leukemia, cytotoxic drugs)	Infection with urea-splitting organisms (*Proteus, Pseudomonas, Providencia, Klebsiella, Mycoplasma, Serratia, S. aureus*) results in alkaline urinary pH and precipitation of struvite (magnesium ammonium phosphate)	Autosomal recessive defect in small bowel mucosal absorption and renal tubular absorption of dibasic amino acids results in "COLA" in urine (cystine, ornithine, lysine, arginine)
Key Features	Radiopaque on KUB x-ray Reducing dietary Ca^{2+} is NOT an effective method of prevention/treatment	Radiolucent on KUB x-ray Radiopaque on CT Acidic urine, pH <5.5 (NOT necessarily elevated urinary uric acid)	Perpetuates UTI because the stone itself harbours organism Stone and all foreign bodies must be cleared to avoid recurrence Associated with staghorn calculi Positive urine dip and cultures Note: *E. coli* infection does not cause struvite stones M:F=3:1, UTI more common in female	Aggressive stone disease seen in children and young adults Recurrent stone formation, FMHx Often staghorn calculi Faintly radiopaque on KUB x-ray Positive urine sodium nitroprusside test, urine chromatography for cystine
Treatment Medical if stone <5 mm and no complications Procedural/Surgical treatment if stone >5 mm or presence of complications Can observe selected, asymptomatic renal stones	Fluids to increase urine volume to >2 L/d For calcium stones: increase citrate in diet, reduce salt, moderate oxalate-rich foods, weight loss Calcium oxalate: thiazides, ± potassium citrate, ± allopurinol Mixed calcium and struvite: ABx (stone must be removed to treat infection)	Increased fluid intake Alkalinization of urine to pH 6.5 to 7 (potassium citrate, sodium bicarbonate) ± allopurinol Be careful not be make urine too alkaline (pH >7), can result in calcium phosphate stones	Complete stone clearance ABx for 6 wk Regular follow-up urine cultures	Increased fluid intake (3-4 L of urine/d) Alkalinize urine (bicarbonate, potassium citrate), penicillamine/α-mercaptopropionylglycine or Captopril (form complex with cystine) SWL not effective

Urological Neoplasms

Approach to Renal Mass

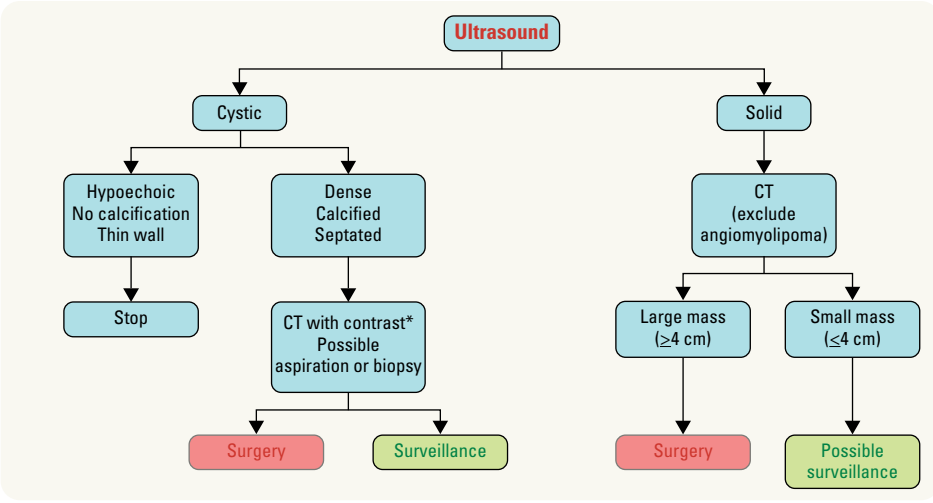

Figure 13. Workup of a renal mass
*Imaging modality may be different in cases of contrast allergy or elevated creatinine

There is controversy over optimal management of small renal masses

Percutaneous needle biopsies of cystic renal masses may lead to peritoneal seeding

Tuberous Sclerosis
- Syndrome characterized by mental retardation, epilepsy, and adenoma sebaceum
- 45-80% of patients also present with angiomyolipomas, which are often multiple and bilateral

Benign Renal Neoplasms

CYSTIC KIDNEY DISEASE

- simple cysts: usually solitary or unilateral
  - very common: up to 50% at age 50
  - usually incidental finding on abdominal imaging
  - Bosniak Classification is used to stratify for risk of malignancy based on cyst features from contrast CT
- polycystic kidney disease
  - autosomal recessive: multiple bilateral cysts, often leading to early renal failure in infants
  - autosomal dominant: progressive bilateral disease leading to HTN and renal failure, adult-onset
- medullary sponge kidney: cystic dilatation of the collecting ducts
  - usually benign course, but patients are predisposed to stone disease
- von Hippel-Lindau syndrome: multiple bilateral cysts and/or renal cell carcinomas (50% incidence of RCC)
  - renal cysts, cerebellar, spinal and retinal hemangioblastomas, pancreatic and epididymal cysts, pheochromocytomas

Table 14. Bosniak Classification of Renal Cysts

Class	Features	Risk of Malignancy	Management Plan
I (simple cyst)	Round, no septa/calcifications/ enhancement, homogeneous, <20 HU	Near zero	No follow-up
II (simple cyst)	Thin septum (<1 mm), fine calcification, no enhancement, <3 cm, >20 HU	Minimal	No follow-up
IIF (minimally complex cyst)	Multiple thin septa, calcifications, no enhancement, >3 cm, >20 HU	5-20%	Follow-up, imaging q6-12 mo, surgical resection if lesion evolves
III (complex cyst)	Irregular, thickened, calcified septa with enhancement	>50% * growing literature suggesting might be lower	Surgical resection * growing literature suggesting surveillance might be safe
IV (likely malignant)	Irregular, thickened, calcified septa with enhancement, enhancing soft-tissue components	>90%	Surgical resection

Table 15. Benign Renal Masses

	Angiomyolipoma (Renal Hamartoma)	Renal Oncocytoma
Epidemiology	<10% of adult renal tumours F>M 20% associated with tuberous sclerosis (especially if multiple, recurrent)	3-7% of renal tumours M>F Oncocytomas also found in adrenal, thyroid, and parathyroid glands
Characteristics	Clonal neoplasm consisting of blood vessels (angio-), smooth muscle (-myo-), and fat (-lipoma) May extend into regional lymphatics and other organs and become symptomatic	Spherical, capsulated with possible central scar Histologically organized aggregates of eosinophilic cells originating from intercalated cells of collecting duct
Diagnosis	Incidental finding on CT Negative attenuation (-20 HU) on CT is pathognomonic Rare presentation of hematuria, flank pain, and palpable mass (same as RCC)	Incidental finding on CT Difficult to distinguish from RCC on imaging – treated as RCC until proven otherwise Biopsy may be performed to rule out malignancy
Management	May consider surgical excision or embolization if symptomatic (pain, bleeding) or higher risk of bleeding (e.g. pregnancy) Potential role for mechanistic target of rapamycin (mTOR) inhibitors in unresectable/metastatic disease Follow with serial U/S	Surveillance for most Partial/radical nephrectomy for large masses

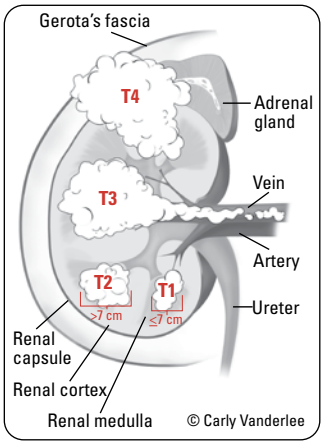

Figure 14. RCC staging

Malignant Renal Neoplasms

RENAL CELL CARCINOMA

Etiology
- cause unknown
- originates from proximal convoluted tubule epithelial cells in clear cell subtype (most common)
- hereditary forms seen with von Hippel-Lindau syndrome and hereditary papillary renal carcinoma

Epidemiology
- 85% of primary malignant tumours in kidney, ~3% of all malignancies
- M:F=1.5:1
- peak incidence at ages 50-60

Pathology
- histological subtypes: clear cell (75-85%), papillary (10-15%), chromophobe (5-10%), collecting duct (<1%), other (<1%)
- sarcomatoid elements in any subtype is a marker of poor prognosis

Risk Factors
- top 3 risk factors: smoking, HTN, obesity
- end-stage renal disease (acquired renal cystic disease)
- role of environmental exposures (aromatic hydrocarbons, etc.) remains an unproven risk factor for development of RCC

Clinical Features
- usually asymptomatic: frequently diagnosed incidentally by U/S or CT (>50%)
- indicators for poor prognosis: weight loss, weakness, anemia, bone pain
- classic "too late triad" found in 10-15%
  - gross hematuria 50%
  - flank pain <50%
  - palpable mass <30%
- metastases: seen in a 1/3 of new cases; additional 20-40% will go on to develop metastases (mostly in late presentations or large tumours)
  - most common sites: bone, brain, lung, and liver
  - may invade renal veins and inferior vena cava (IVC) lumen
  - this may result in ascites, hepatic dysfunction, right atrial tumour, varicocele, and pulmonary emboli

Role of environmental exposures (aromatic hydrocarbons, etc.) remains an unproven risk factor for development of RCC

RCC Systemic Effects: Paraneoplastic Syndromes (10-40% of Patients)
- Hematopoietic disturbances: anemia, polycythemia, raised Erythrocyte Sedimentation Rate (ESR)
- Endocrinopathies: hypercalcemia (increased vitamin D hydroxylation), erythrocytosis (increased erythropoietin), HTN (increased renin), production of other hormones (prolactin, gonadotropins, TSH, insulin, and cortisol)
- Hepatic cell dysfunction or Stauffer syndrome: abnormal LFTs, decreased WBC count, fever, areas of hepatic necrosis; no evidence of metastases; reversible following removal of primary tumour
- Hemodynamic alterations: systolic HTN (due to arteriovenous shunting), peripheral edema (due to caval obstruction)

Investigations
- routine labs for paraneoplastic syndromes (CBC, ESR, LFTs, extended electrolytes)
- U/A
- renal U/S: solid vs. cystic lesion
- contrast-enhanced CT: higher sensitivity than U/S for detection of renal masses and for staging purposes
- MRI: useful for evaluation of complex cystic lesions indeterminate on CT; good way to assess IVC thrombus
- renal biopsy: to confirm diagnosis, if considering observation or other non-surgical ablative therapy
- genetic testing: consider if FHx of von Hippel-Lindau syndrome, non-clear cell carcinoma, bilateral/multifocal tumour, onset ≤45 yr, FHx of renal tumour, or any renal tumour with Hx of pneumothorax, dermatologic findings, associated tumours, lymphangiomyomatosis, or childhood seizure disorder

Staging
- involves abdo/pelvis CT, CXR, liver enzymes and LFTs, bone/head imaging (if symptoms dictate)

Table 16. 2018 TNM Classification of Renal Cell Carcinoma (AJCC 8th edition)

T	N	M
TX: primary tumour cannot be assessed	**NX**: regional lymph nodes cannot be assessed	**cM0**: no evidence of distant metastasis
T1: tumour <7 cm, confined to renal parenchyma **T1a**: <4 cm **T1b**: 4-7 cm	**N0**: no regional lymph node metastasis **N1**: metastasis in regional lymph nodes	**cM1**: presence of distant metastasis **pM1**: presence of distant metastasis, microscopically confirmed
T2: tumour >7 cm, confined to renal parenchyma **T2a**: >7 cm but ≤10 cm **T2b**: >10 cm	**N Suffix** **(sn)**: regional lymph node metastasis identified by SLN biopsy only **(f)**: regional lymph node metastasis identified by FNA or core needle biopsy only	
T3: tumour extends into major veins or perinephric tissues, but NOT into ipsilateral adrenal or beyond Gerota's fascia **T3a**: into renal vein or sinus fat **T3b**: into infradiaphragmatic IVC **T3c**: into supradiaphragmatic IVC		
T4: tumour extends beyond Gerota's fascia including extension into ipsilateral adrenal		
T Suffix **(m)**: if synchronous primary tumours are found in single organ		

Treatment
- surgical (open, laparoscopic, robotic)
  - radical nephrectomy: en bloc removal of kidney, tumour, ipsilateral adrenal gland (in upper pole tumours) and intact Gerota's capsule
  - partial nephrectomy (parenchyma-sparing): small tumour (roughly <4 cm) or solitary kidney/bilateral tumours
  - surgical removal of solitary metastasis may be considered
- ablative techniques (percutaneous or lap-assisted)
  - radiofrequency ablation (RFA)
  - cryoablation
  - palliative radiation to painful bony lesions
- therapy for advanced stage
  - new immunologic inhibitors (e.g. pembrolizumab, ipilimumab, nivolumab)
  - tyrosine kinase inhibitors for metastatic disease (e.g. sunitinib, sorafenib)
  - IFNα: monotherapy has been largely replaced by molecularly targeted agents listed above

Prognosis
- stage at diagnosis most important prognostic factor
  - T1: 90-100% 5 yr survival
  - T2-T3: 60% 5 yr survival
  - metastatic disease: <5% 10 yr survival
- predictors of relapse: tumour grade, local extent of the primary tumour, presence of local metastases, histological subtype

Carcinoma of the Renal Pelvis and Ureter

Etiology
- risk factors include:
  - smoking
  - dietary/chemical exposures (aristolochic acid, industrial dyes and solvents: aniline dyes)
  - analgesic misuse (acetaminophen, ASA, and phenacetin)
  - Balkan nephropathy
  - prior exposure to cyclophosphamide

Epidemiology
- rare: accounts for 5% of all UC
- frequently multifocal, 2-5% are bilateral
- M:F=3:1
- relative incidence: bladder:renal:ureter=100:10:1
- consider Lynch syndrome if PMHx for other malignancies (e.g. colorectal, stomach, prostate, endometrial, etc.)

Pathology
- 85% are papillary UC; others include SCC and adenocarcinoma
- UC of ureter and renal pelvis are histologically similar to bladder UC

Clinical Features
- gross/microscopic hematuria
- flank pain
- storage or voiding symptoms (dysuria only if lower urinary tract involved)
- flank mass ± hydronephrosis (10-20%)

Investigations
- CT urogram
- cystoscopy and retrograde pyelogram

Treatment
- radical nephroureterectomy with excision of ipsilateral bladder cuff
- distal ureterectomy for distal ureteral tumours with concomitant ureteral reimplant
- segmental resection with uretero-ureterostomy for some mid-ureteral tumours is also done
- emerging role for endoscopic laser ablation in patients with low grade disease, poor baseline renal health

Bladder Carcinoma

Etiology
- unknown, but environmental risk factors include:
  - smoking (main factor – implicated in 60% of new cases)
  - aromatic amines: naphthylamines, benzidine, tryptophan, phenacetin metabolites
  - cyclophosphamide
  - prior Hx of radiation treatment to the pelvis
  - *Schistosoma hematobium* infection (associated with SCC)
  - chronic irritation: cystitis, chronic catheterization, bladder stones (associated with SCC)
  - aristolochic acid: associated with Balkan nephropathy (renal failure, upper tract UC) and Chinese herbal nephropathy

Epidemiology
- 2nd most common urological malignancy
- M:F=3:1, more common among whites than blacks
- mean age at diagnosis is 65 yr

Pathology
- classification
  - UC >90%
  - SCC 5-7%
  - adenocarcinoma 1%
  - others <1%
- stages and prognoses of UC at diagnosis
  - non-muscle invasive (75%) ➔ >80% overall survival
    - 15% of these will progress to invasive UC
    - majority of these patients will have recurrence
  - invasive (25%) ➔ 50-60% 5 yr survival
    - 85% have no prior history of superficial UC (i.e. *de novo*)
    - 50% have occult metastases at diagnosis, and most of these will develop overt clinical evidence of metastases within 1 yr – lymph nodes, lung, peritoneum, liver

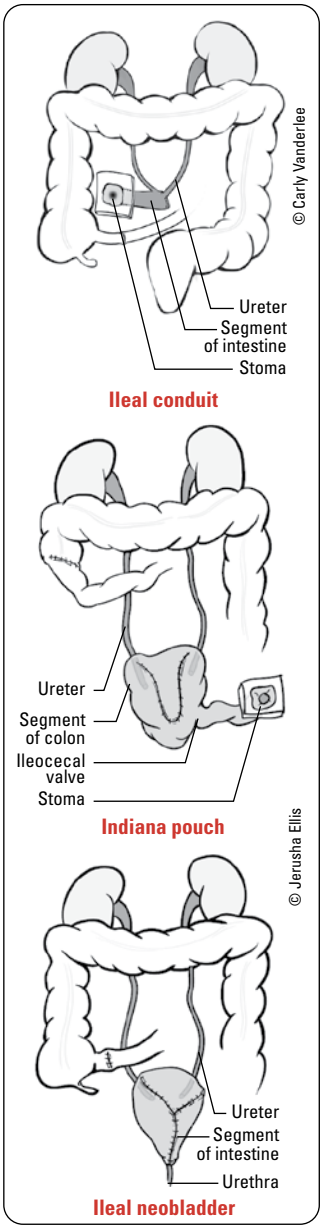

Figure 15. Ileal conduit, Indiana pouch, ileal neobladder

Differential Diagnosis of Filling Defect in Urinary Tract
- Urothelial carcinoma (differentiate via cytology and CT scan)
- Uric acid stone (differentiate via cytology and CT scan)
- Blood clot
- Pyelitis cystica
- Papillary necrosis
- Fungus ball
- Gas bubble from gas producing organisms

- carcinoma *in situ* ➔ flat, non-papillary erythematous lesion characterized by dysplasia confined to urothelium
  - more aggressive, worse prognosis, higher recurrence rates following radical cystectomy, associated with radioresistance
  - usually multifocal
  - may progress to invasive UC

Clinical Features
- asymptomatic (20%)
- hematuria (key symptom: 85-90% at the time of diagnosis)
- pain (50%) ➔ location determined by size/extent of tumour (e.g. flank, suprapubic, perineal, abdominal, etc.)
- clot retention (17%)
- storage urinary symptoms ➔ consider carcinoma *in situ*
- palpable mass on bimanual exam ➔ likely muscle invasion
- obstruction of ureters ➔ hydronephrosis and uremia (N/V and diarrhea); bad prognostic factor

Investigations
- U/A, urine C&S, urine cytology
- U/S
- CT scan with contrast ➔ look for filling defects in upper tracts
- cystoscopy with biopsy (if small lesion)
- TURBT (gold standard, diagnostic, and often therapeutic) ➔ establish diagnosis and determine depth of penetration
  - involvement of muscularis propria confirms muscle invasion (T2)
- specific bladder tumour markers (e.g. NMP-22, BTA, Immunocyt, FDP); utility in clinical practice debatable

Grading
- low grade: ≤10% invasive, 60% recur locally
- high grade: 50-80% are invasive or are expected to progress to invasive over time

Staging
- for invasive disease: examination under anesthesia following TURBT, CT, or MRI of abdomen and pelvis, CT or MR urography, CT chest or CXR, bone scan in setting of bony pain/hypercalcemia/elevated ALP (metastatic workup)

Table 17. 2018 TNM Classification of Bladder Carcinoma (AJCC 8th edition)

T	N	M
TX: primary tumour cannot be assessed	**NX**: lymph nodes cannot be assessed	**cM0**: no distant metastasis
T0: no evidence of primary tumour **Ta**: noninvasive papillary carcinoma **Tis**: carcinoma *in situ*: "flat tumour"	**N0**: no lymph node metastasis	**cM1**: distant metastasis **cM1a**: distant metastasis limited to lymph nodes beyond the common iliacs **cM1b**: non-lymph-node distant metastasis
T1: tumour invades subepithelial connective tissue	**N1**: single regional lymph node metastasis in the true pelvis (hypogastric, obturator, external iliac, or presacral lymph node)	**pM1**: distant metastasis, microscopically confirmed **pM1a**: distant metastasis limited to lymph nodes beyond the common iliacs, microscopically confirmed **pM1b**: non-lymph-node distant metastasis microscopically confirmed
T2: tumour invades muscularis propria **pT2a**: tumour invades superficial muscularis propria (inner half) **pT2b**: tumour invades deep muscularis propria (outer half)	**N2**: multiple regional lymph node metastasis in the true pelvis (hypogastric, obturator, external iliac, or presacral lymph node metastasis)	
T3: tumour invades perivesical tissue **pT3a**: microscopically **pT3b**: macroscopically (extravesical mass)	**N3**: lymph node metastasis to the common iliac lymph nodes	
T4: tumour invades any of the following: prostatic stroma, seminal vesicles, uterus, vagina, pelvic wall, abdominal wall **T4a**: tumour invades prostatic stroma, uterus, vagina **T4b**: tumour invades pelvic wall, abdominal wall	**N Suffix** **(sn)**: regional lymph node metastasis identified by SLN biopsy only **(f)**: regional lymph node metastasis identified by FNA or core needle biopsy only	
T Suffix **(m)**: synchronous primary tumours are found in single organ		

The "field defect" theory helps to explain why UC has multiple lesions and has a high recurrence rate. The entire urothelium (pelvis to bladder) is bathed in carcinogens

The ENTIRE urinary tract must be evaluated in patients with hematuria unless there is clear evidence of glomerular bleeding (e.g. red cell casts, dysmorphic RBCs, etc.)

Cystoscopy is the initial procedure of choice for the diagnosis and staging of urothelial malignancy

Unexplained hematuria in any individual >40 y/o must be investigated to rule out a malignancy

Tumour grade is the single most important prognostic factor for progression

See Landmark Urology Trials table for more information on neoadjuvant chemotherapy plus cystectomy compared with cystectomy alone for improved outcomes in patients with locally advanced bladder cancer.

NMIBC and BCG
AHRQ Publication 2015:15-EHC017-EF #153
Summary: BCG is the only intravesical therapy associated with decreased risk of bladder cancer progression; however, it is also associated with a high rate of adverse events. More research is needed to define optimal dose/regimen.
Methods: Review of Ovid Medline, Cochrane Central Register of Controlled Trials, Cochrane Database of SR, Health Technology Assessment, National Health Sciences Economic Evaluation, Database of Abstract of Review of Effects for studies on NMIBC interventions, including intravesical therapy.
Results: BCG is superior in prevention of bladder cancer recurrence compared to no intravesical therapy. BCG is superior to doxorubicin, epirubicin, and mitomycin in prevention of bladder cancer recurrence.

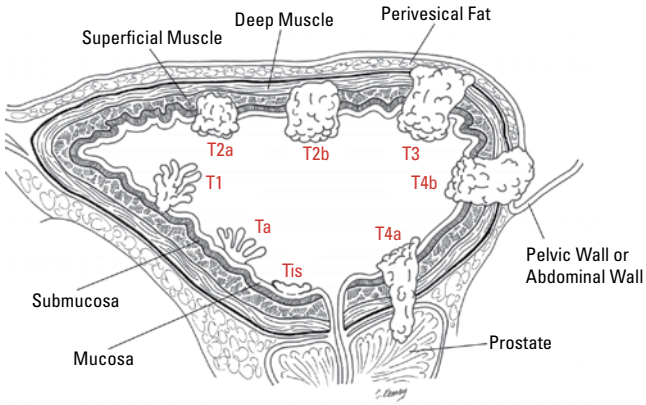

Figure 16. UC of bladder

See Landmark Urology Trials table for more information on 10-yr outcomes for patients with localized prostate cancer after monitoring, surgery, or radiotherapy.

Treatment

Non-muscle invasive	Muscle invasive	Advanced/Metastatic
Low risk (Ta low-grade) TURBT + intravesical chemo Follow up with cystoscopy and cytology **Intermediate risk (Multifocal, recurrent Ta)** TURBT + intravesical chemo BCG (1 yr) **High risk (T1, Tis, Ta high-grade)** TURBT ± intravesical chemo Repeat TURBT (2-6 wk) BCG (3 yr)	**T2, T3** Radical cystectomy + PLND + urinary diversion (see Figure 15) – Radical cystectomy (male): Removal of bladder and prostate en bloc – Radical cystectomy (female): Removal of bladder, uterus, ovaries and anterior vagina (reproductive organs may be spared with anterior tumours) Radical local treatment Maximal TURBT + chemoradiation	**T4, N+, M+** Chemo ± radiation ± cystectomy

©Amy Cao 2019

Figure 17. Treatment for bladder carcinoma
*Radical cystectomy (male): removal of bladder and prostate en block, (female): removal of bladder, uterus, ovaries, and anterior vagina (reproductive organs may be spared with anterior tumours)

Prognosis
- depends on stage, grade, size, number of lesions, recurrence, and presence of CIS
  - T1: 90% 5 yr survival
  - T2: 55% 5 yr survival
  - T3: 30% 5 yr survival
  - T4/N+/M+: <5% 5 yr survival

Prostate Cancer

Etiology
- not known
- risk factors
  - age >50 yr, risk increases 1% per yr after 65 yr
  - increased incidence in persons of African descent
  - high dietary fat (2x)
  - FMHx
    - 1st degree relative (2x)
    - 1st and 2nd degree relatives (9x)
  - positive BRCA (BReast CAncer gene) mutation

Epidemiology
- most prevalent cancer in males
- 3rd leading cause of male cancer deaths (following lung and colon)
- up to 50% risk of CaP at age 50
- lifetime risk of death from CaP is 3%
- 75% diagnosed between ages 60 and 85; mean age at diagnosis is 65

Pathology
- adenocarcinoma
  - >95%, often multifocal
- urothelial carcinoma of the prostate (4.5%)
  - associated with UC of bladder; does NOT follow TNM staging below; not hormone-responsive
- endometrial (rare)
  - carcinoma of the utricle

Anatomy
- 60-70% of nodules arise in the peripheral zone
- 10-20% arise in the transition zone
- 5-10% arise in the central zone

Clinical Features
- usually asymptomatic
- most commonly detected by DRE, elevated PSA, or as an incidental finding on TURP
  - DRE: hard irregular nodule or diffuse dense induration involving one or both lobes
  - PSA: see *PSA Screening*, U29
- locally advanced disease
  - storage and voiding symptoms, ED (all uncommon without spread)
- metastatic disease
  - bony metastases to axial skeleton common
  - visceral metastases are less common (liver, lung, and adrenal gland most common sites)
  - leg pain and edema with nodal metastases obstructing lymphatic and venous drainage

Early Detection of Prostate Cancer: American Urological Association Guidelines
J Urol 2013;190: 419.
1. For men aged 55 to 69 yr who are considering PSA screening, it is strongly recommended to proceed based on values and preferences following shared decision-making.
2. Routine PSA screening in men between ages 40 to 54 yr at average risk is NOT recommended .
3. Routine PSA screening in men age 70+ yr or any man with less than a 10 to 15 yr life expectancy is NOT recommended.

Methods of Spread
- local invasion
- lymphatic spread to regional nodes
  - obturator > iliac > presacral/para-aortic
- hematogenous dissemination occurs early

Investigations
- DRE
- PSA elevated in the majority of patients with CaP
- TRUS-guided needle biopsy
- bone scan (only if bone pain, high-risk disease, Gleason score >7, or PSA >20 ng/mL)
- CT scanning to assess metastases
- MRI: being investigated for possible role in detection, staging, MRI-guided biopsy, and active surveillance

Table 18. 2018 TNM Classification of Prostate Carcinoma (AJCC 8th edition)

T	N	M
TX: primary tumour cannot be assessed	**NX**: regional lymph nodes were not assessed	**M0**: no distant metastasis
T0: no evidence of primary tumour	**N0**: no regional lymph node metastasis	**cM1**: distant metastasis **cM1a**: nonregional lymph nodes **cM1b**: bone(s) **cM1c**: other site(s) with or without bone disease
T1: clinically undetectable tumour, normal DRE and TRUS **T1a**: tumour incidental histologic finding in <5% of tissue resected **T1b**: tumour incidental histologic finding in >5% of tissue resected **T1c**: tumour identified by needle biopsy (due to elevated PSA level)	**N1**: spread to regional lymph nodes **N Suffix** **(sn):** regional lymph node metastasis identified by SLN biopsy only **(f):** regional lymph node metastasis identified by FNA or core needle biopsy only	**pM1**: distant metastasis, microscopically confirmed **pM1a**: nonregional lymph nodes, microscopically confirmed **pM1b**: bone(s) microscopically confirmed **pM1c**: other site(s) with or without bone disease, microscopically confirmed
T2: palpable, confined to prostate **T2a**: tumour involving ≤ one half of one lobe **T2b**: tumour involving > one half of one lobe, but not both lobes **T2c**: tumour involving both lobes		
T3: tumour extends through prostate capsule **T3a**: extracapsular extension (unilateral or bilateral) **T3b**: tumour invading seminal vesicle(s)		
T4: tumour invades adjacent structures (besides seminal vesicles)		
T Prefix **(c)**: clinical T **(p)**: pathological T. There is no pathological T1		
T Suffix **(m)**: synchronous primary tumours are found in single organ		

Table 19. Prostate Cancer Mortality Risk

	Low-Risk (if any of following)	Intermediate-Risk (if any of following)	High-Risk (if any of following)
PSA	<10	10-20	>20
Gleason Score	<7 (Gleason Group 1)	7 (Gleason Group 2 and 3)	8-10 (Gleason Group 4 and 5)
Stage	pT1-2a	pT2b-T2c	pT3/4

Treatment

- T1/T2 (localized, low-risk)
  - if adequate life expectancy or no other significant comorbidities, consider active surveillance vs. definitive local treatment (RP, brachytherapy, or EBRT)
  - active surveillance for low-risk, small volume Gleason score <7 prostate cancer shown to be safe for most
  - minimal differences in cure or recurrence rates between definitive treatment modalities
  - in older population: watchful waiting and palliative treatment for symptomatic progression
  - alternative treatment options include: HIFU, cryoablation, focal laser ablation
- T1/T2 (intermediate or high-risk)
  - definitive therapy over active surveillance
  - watchful waiting in elderly or infirm
- T3, T4
  - ADT (with calcium, vitamin D, bisphosphonates) + EBRT/docetaxel/abiraterone
  - enzalutamide, apalutamide
  - radiation therapy for oligometastatic disease (case-by-case basis)
- N >0 or M >0
  - requires hormonal therapy/palliative radiotherapy for metastases; may consider combined androgen blockade
  - bilateral orchiectomy – decreases testosterone production by 90%
  - GnRH agonists (e.g. leuprolide, goserelin), see Table 28, U47, GnRH antagonist (e.g. degarelix)
  - antiandrogens (e.g. bicalutamide)
  - local irradiation of painful secondaries or half-body irradiation
- castration-resistant prostate cancer (CRPC)
  - ADT should be maintained
  - non-metastatic CRPC: observation vs apalutamide, enzalutamide, or darolutamide
  - metastatic CRPC: abiraterone, enzalutamide, docetaxel-based chemotherapy
    - post-docetaxel: second-line chemotherapy cabazitaxel
    - if symptomatic without visceral metastases: radium-223
    - HRR mutation: olaparib
    - bone metastases: denosumab and/or zoledronic acid is recommended +/- palliative radiation

Table 20. Treatment Options for Localized Prostate Cancer

Modality	Population Considered	Limitations
Watchful Waiting	Short life expectancy (<5-10 yr); will likely only receive non-curative hormonal therapy if disease progresses	Disease progression
Active Surveillance (serial PSA, DRE, and biopsies)	Low grade disease, good follow-up; is still considering more curative treatment if disease progresses	Disease progression; decrease in QOL associated with serial testing; risks associated with biopsies; no optimal monitoring schedule has been defined to date
Brachytherapy	Low volume, low PSA (<10), low grade	ED (50%), long-term effectiveness not well-established
EBRT	Locally advanced disease, older patients	Radiation proctitis (5%), ED (25-50%), risk of rectal and bladder cancer
RP	Young patients (<75 yr), high-risk disease	Incontinence (10%), ED (30-50%)

*Other options include cryosurgery, HIFU, hormonal ablation

Prognosis

- T1-T2: comparable to normal life expectancy
- T3-T4: 40-70% 10 yr survival
- N^+ and/or M^+: 4% 5 yr survival
- prognostic factors: tumour stage, tumour grade, PSA value, PSA doubling time

PSA Screening

Digital Rectal Exam
- should be included as part of initial screening
- suspicious findings: abnormal feeling, nodularity, focal lesion, discrete change in texture/fullness/symmetry

Prostate Specific Antigen
- glycoprotein produced by epithelial cells of prostate gland
- leaks into circulation in setting of disrupted glandular architecture
- value of <4 ng/mL traditionally considered as cut-off to differentiate normal from pathologic value, but no single justifiable cut-off point
- measured serum PSA is a combination of free (15%) and bound PSA (85%)
- decreased free:total PSA, elevated PSA velocity and elevated PSA density associated with increased CaP rates

Screening Recommendations

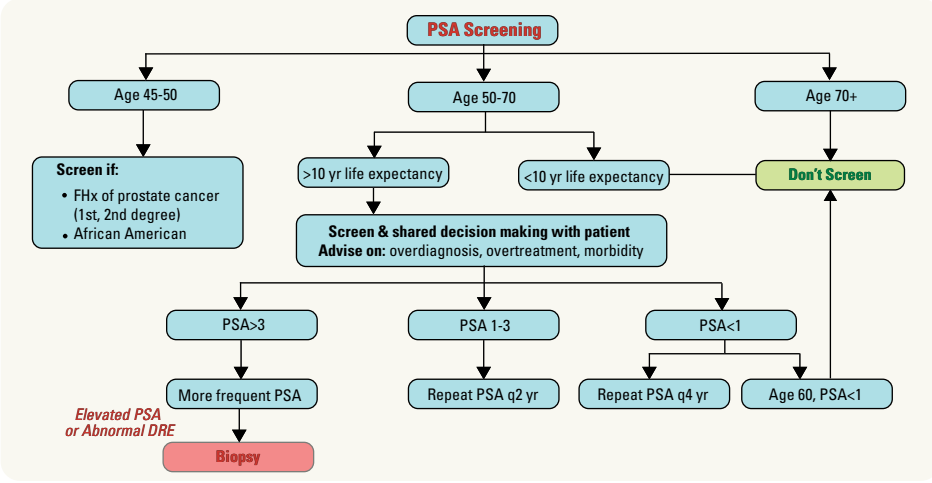

Figure 18. Canadian Urological Association guidelines on PSA screening (2017)

Causes of Increased PSA
BPH, prostatitis, prostatic ischemia/infarction, prostate biopsy/surgery, prostatic massage, acute urinary retention, urethral catheterization, cystoscopy, TRUS, strenuous exercise, perineal trauma, ejaculation, acute renal failure, coronary bypass graft, radiation therapy

PSA is specific to the PROSTATE, but NOT to prostate cancer

Long-Term Follow-Up on PSA Screening
Lancet 2014;384:2027-2035
Summary: At 13 yr follow-up, PSA screening is favourable, showing a significant 21% relative prostate cancer mortality reduction. The number needed to screen and to treat from this trial were lower than those observed in breast cancer trials. However, the risks associated with screening need to be considered when considering population-level screening programs.
Methods: Multi-centre RCT with predefined central database, analysis, and core age group (55-69 yr) evaluating PSA in 8 European countries. Incidence and mortality truncated at 9, 11, and 13 yr follow-up in the intervention arm was compared to control arm.
Results: RR of PCa incidence between intervention and control arms was 1.91 after 9 yr follow-up, 1.66 at 11 yr follow-up, and 1.67 at 13 yr follow-up. RR of PCa mortality was 0.85, 0.78, and 0.79, at 9, 11, 13 yr follow-up, respectively. At 13 yr follow-up in PSA screening group, relative RR is 21%, and absolute RR from death is 1.28 per 1000 men.

Testicular Tumours

Etiology/Risk Factors
- cryptorchidism, atrophy, sex hormones, HIV infection, infertility, FMHx, PMHx of testicular cancer

Epidemiology
- rare, but most common solid malignancy in young males 15-35 yr
- any solid testicular mass or acute hydrocoele in young patient – must rule out malignancy
- slightly more common in right testis (corresponds with slightly higher incidence of right-sided cryptorchidism)
- 2-3% bilateral (simultaneously or successively)

Pathology
- primary
  - 1% of all malignancies in males
  - cryptorchidism has increased risk (10-40x) of malignancy
  - 95% are germ cell tumours (all are malignant)
    - seminoma (35%) ➔ classic, anaplastic, spermatocytic
    - NSGCT ➔ embryonal cell carcinoma (20%), teratoma (5%), choriocarcinoma (<1%), yolk sac (<<1%), mixed cell type (40%)
  - 5% are non-germ cell tumours (usually benign) ➔ Leydig (testosterone, precocious puberty), Sertoli (gynecomastia, decreased libido)
- secondary
  - male >50 yr
  - usually lymphoma or metastases (e.g. lung, prostate, GI)

Clinical Features
- painless testicular enlargement (painful if intratesticular hemorrhage or infarction)
- dull, heavy ache in lower abdomen, anal area, or scrotum
- associated hydrocele (10%)
- coincidental trauma (10%)
- infertility (rarely presenting complaint)

- gynecomastia due to secretory tumour effects
- supraclavicular and inguinal lymphadenopathy
- abdominal mass (retroperitoneal lymph node metastases)

Methods of Spread

- local spread follows lymphatics
  - right ➔ medial, paracaval, anterior, and lateral nodes
  - left ➔ left lateral and anterior paraaortic nodes
  - "cross-over" metastases from right to left are fairly common, but no reports from left to right
- hematogenous most commonly to lung, liver, bones, and kidney

Investigations

- diagnosis is established by pathological evaluation of specimen obtained by radical inguinal orchidectomy
- tumour markers (β-hCG, LDH, AFP)
  - β-hCG and AFP are positive in 85% of non-seminomatous tumours
  - elevated marker levels return to normal postoperatively if no metastasis
  - β-hCG positive in 7% of pure seminomas, AFP never elevated with seminoma
- testicular U/S (hypoechoic area within tunica albuginea = high suspicion of testicular cancer)
- evidence of testicular microlithiasis is not a risk factor for testicular cancer
- needle aspiration contraindicated

Testes and scrotum have different lymphatic drainage, therefore trans-scrotal approach for biopsy or orchiectomy should be avoided

Staging

- clinical: CXR (lung metastases), markers for staging (β-hCG, AFP, LDH), CT abdomen/pelvis (retroperitoneal lymphadenopathy)
  - stage I: disease limited to testis, epididymis, or spermatic cord
  - stage II: disease limited to the retroperitoneal nodes
  - stage III: disease metastatic to supradiaphragmatic nodal or visceral sites

Table 21. 2018 TNM Classification of Testicular Carcinoma (AJCC 8th edition)

T	N	M
TX: primary tumour cannot be assessed	**NX**: regional lymph nodes were not assessed	**M0**: no distant metastases
T0: no evidence of primary tumour	**N0**: no regional lymph node metastasis	**cM1**: distant metastases **cM1a**: non-retroperitoneal nodal or pulmonary metastases **cM1b**: non-pulmonary visceral metastases
Tis: intratubular germ cell neoplasia	**N1**: metastasis with a lymph node mass 2 cm or less in greatest dimension; or multiple lymph nodes, none more than 2 cm in greatest dimension	**pM1**: distant metastases, microscopically confirmed **pM1a**: non-retroperitoneal nodal or pulmonary metastases, microscopically confirmed **pM1b**: non-pulmonary visceral metastases, microscopically confirmed
T1: limited to testis and epididymis without lymphovascular invasion **T1a**: tumour <3 cm **T1b**: tumour >3 cm	**N2**: metastasis with a lymph node mass more than 2 cm but not more than 5 cm in greatest dimension	
T2: limited to testis and epididymis with lymphovascular invasion or invading hilar soft tissue or epididymis, or penetrating visceral mesothelial layer covering the external surface of tunica albuginea with or without lymphovascular invasion	**N3**: metastasis with a lymph node mass more than 5 cm in greatest dimension	
T3: invasion of the spermatic cord ± lymphovascular invasion	**N Prefix** **(c)**: clinical N **(p)**: pathological N	
T4: invasion of the scrotum ± invasion	**N Suffix** **(sn)**: regional lymph node metastasis identified by SLN biopsy only **(f)**: regional lymph node metastasis identified by FNA or core needle biopsy only	
T Prefix **(c)**: clinical T. except for Tis confirmed by biopsy an T4, the extent of primary tumour is classified by radical orchiectomy **(p)**: pathological T. subclassification of pT1 applies only to pure seminoma		
T Suffix **(m):** synchronous primary tumours are found in single organ		

Management

- radical orchiectomy through inguinal incision for all stages - ligate spermatic cord inside inguinal canal
- consider sperm banking, testicular prosthesis
- adjuvant therapies (see Figure 19, U31)

Orchiopexy
Surgical descent (orchiopexy) of undescended testis does not eliminate the risk of malignancy, but allows for earlier detection by self-examination and reduces the risk of infertility

Prognosis

- 99% cured with stage I and II disease
- 70-80% complete remission with advanced disease

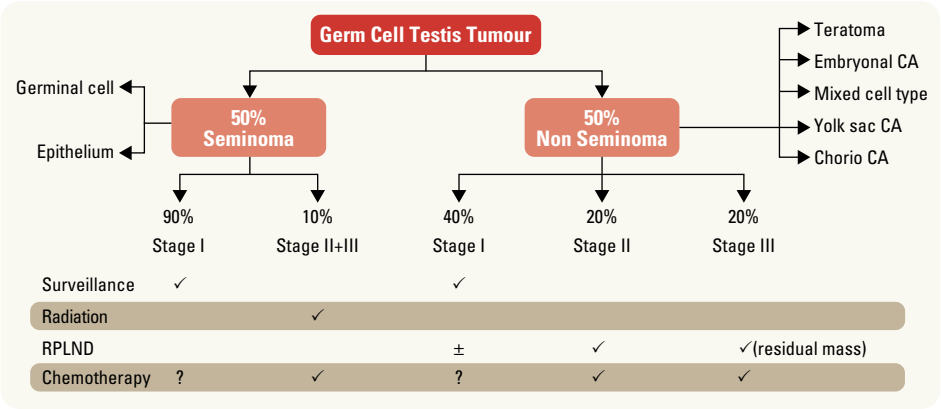

Figure 19. Adjuvant management of testicular cancer post-orchiectomy
Adapted from Dr. MAS Jewett

Layers of the Scrotum

Dartos muscle and fascia
External spermatic fascia
Cremasteric fascia
Internal spermatic fascia
Tunica vaginalis
Tunica albuginea

Penile Tumours

Epidemiology
- rare (<1% of cancer in males in U.S.)
- most common in ages 50-59

Benign
- cyst, hemangioma, nevus, papilloma

Pre-Malignant
- balanitis xerotica obliterans, leukoplakia, Buschke-Lowenstein tumour (large condyloma)

Pre-invasive Cancer
- carcinoma *in situ*
  - Bowen's disease ➔ crusted, red plaques on the shaft
  - erythroplasia of Queyrat ➔ velvet red, ulcerated plaques on the glans
  - treatment options: local excision, laser, radiation, topical 5-fluorouracil

Malignant
- risk factors
  - chronic inflammatory disease
  - STI
  - phimosis
  - uncircumcised penis
- 2% of all urogenital cancers
- SCC (>95%), basal cell, melanoma, Paget's disease of the penis (extremely rare)
- definitive diagnosis requires full thickness biopsy of lesion
- lymphatic spread (superficial/deep inguinal nodes ➔ iliac nodes) >> hematogenous

Treatment
- wide surgical excision with tumour-free margins (dependent on extent and area of penile involvement) ± lymphadenectomy
- consider less aggressive treatment modalities in CIS (cryotherapy, laser therapy, etc.), if available

Scrotal Masses

Table 22. Differentiating between Scrotal Masses

Condition	Pain	Palpation	Additional Findings
Torsion	+	Diffuse tenderness Horizontal lie of testicle	Absent cremaster reflex, negative Prehn's sign
Epididymitis	+	Epididymal tenderness	Present cremaster reflex, positive Prehn's sign
Orchitis	+	Diffuse tenderness	Present cremaster reflex, positive Prehn's sign
Hematocele	+	Diffuse tenderness	No transillumination
Hydrocele	–	Testis not separable from hydrocele, cord palpable	Transillumination, Hx of trauma
Spermatocele	–	Testis separable from spermatocele, cord palpable	Transillumination
Varicocele	–	Bag of worms	No transillumination, increases in size with valsalva, decrease in size if supine
Indirect Inguinal	– (+ if strangulated)	Testis separable from hernia, cord not palpable, cough impulse may transmit, may be reducible	No transillumination
Tumour	– (+ if hemorrhagic)	Hard lump/nodule	
Generalized/ Dependent Edema	–	Diffuse swelling	Often postoperative or immobilized, check for liver dysfunction
Idiopathic	–		

Varicocele Grading
Grade 1: palpable only with Valsalva manoeuvre
Grade 2: palpable without Valsalva
Grade 3: visible through scrotal skin

Suspect a Retroperitoneal Mass/ Process in a Patient with a Varicocele if:
Acute onset
Right sided (isolated)
Palpable abdominal mass
Does not reduce while supine

Table 23. Benign Scrotal Masses

Type	Varicocele	Spermatocele	Hydrocele	Testicular Torsion	Inguinal Hernia
Definition	Dilatation and tortuosity of pampiniform plexus	A benign, sperm-filled epididymal retention cyst	Collection of serous fluid that results from a defect or irritation in the tunica vaginalis	Twisting of the testicle causing venous occlusion and engorgement as well as arterial ischemia and infarction	Protrusion of abdominal contents through the inguinal canal into the scrotum
Etiology	15% of men Due to incompetent valves in the testicular veins 90% left-sided	Multiple theories, including: Distal obstruction Aneurysmal dilations of the epididymis Agglutinated germ cells	Usually idiopathic Found in 5-10% testicular tumours Associated with trauma/ infection Communicating: patent processus vaginalis, changes size during day (paediatric) Non-communicating: non-patent processus vaginalis (adult)	Trauma Cryptorchidism "Bell clapper deformity" Many occur in sleep (50%) Necrosis of glands in 5-6 h	Indirect (through internal ring, often into scrotum): congenital Direct (through external ring, rarely into scrotum): abdominal muscle weakness
Hx/P/E	"Bag of worms" Often painless Pulsates with Valsalva	Non-tender, cystic mass Transilluminates	Non-tender, intrascrotal mass Cystic Transilluminates	Acute onset severe scrotal pain, swelling GI upsets cases Retracted and transverse testicle (horizontal lie) Negative Phren's sign Absent cremasteric reflex	A small bulge in the groin that may increase in size with Valsalva and disappear when lying down Can present as a swollen or enlarged scrotum Discomfort or sharp pain – especially when straining, lifting, or exercising
Investigations	P/E Valsava	P/E U/S to rule out tumour	U/S to rule out tumour	U/S Doppler with probe over testicular artery Decrease uptake on 99mTc-pertechnetate scintillation scan (doughnut sign)	Hx and P/E Invagination of the scrotum Valsalva
Treatment	Conservative Surgical ligation of testicular veins Percutaneous vein occlusion (coils) Repair may improve sperm count/motility	Conservative Excise if symptomatic	Conservative Needle drainage (high rate of surgical recurrence) Surgical	Emergency surgical exploration and bilateral orchiopexy Definitive diagnosis NOT necessary to take to OR Orchiectomy if absent restoration of flow to testicle	Surgical repair

TORSION OF TESTICULAR APPENDIX

- twisting of testicular/epididymal vestigial appendix

Signs and Symptoms

- clinically similar to testicular torsion, but vertical lie and cremaster reflex preserved
- "blue dot sign"
  - blue infarcted appendage seen through scrotal skin in children (can usually be palpated as small, tender lump)

Indications for Treatment of Varicocele
- Impaired sperm quality or quantity
- Pain or dull ache affecting QOL
- Affected testis fails to grow in adolescents
- Cosmetic indications (especially in adolescents)

Treatment
- analgesia – most will subside over 5-7 d
- surgical exploration and excision if refractory pain

HEMATOCELE
- trauma with bleed into tunica vaginalis
- U/S helpful to exclude fracture of testis which requires surgical repair

Treatment
- ice packs, analgesics, surgical drainage, and hydrocele repair

Acute scrotal swelling/pain in young boys is torsion until proven otherwise

Transillumination refers to light being transmitted through tissue (i.e. due to excess fluid)

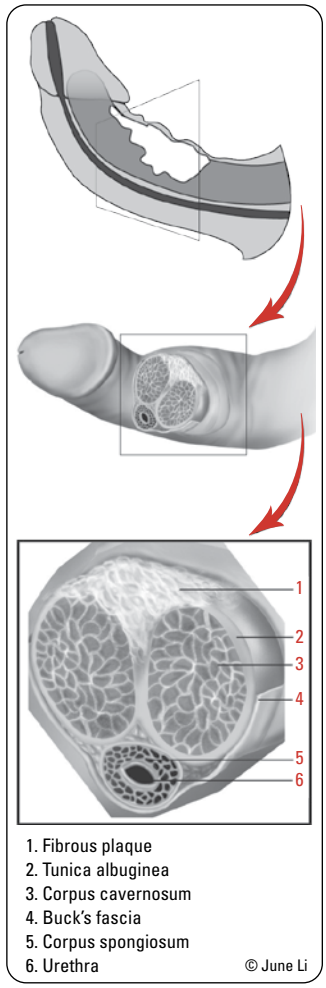
Differential of a Benign Scrotal Mass

HIS BITS
Hydrocele
Infection (epididymitis/orchitis)
Sperm (spermatocele)
Blood (hematocele)
Intestines (hernia)
Torsion
Some veins (varicocele)

Penile Complaints

Table 24. Penile Complaints

Type	Peyronie's Disease	Priapism	Paraphimosis	Phimosis	Premature Ejaculation
Definition	Acquired curvature of penile shaft secondary to fibrous thickening of tunica albuginea	Prolonged erection lasting >4 h in the absence of sexual excitement/desire	Retracted foreskin (behind glans penis) that cannot be reduced	Inability to retract foreskin over glans penis	Ejaculation prior to when one or both partners desire it, either before or soon after intimacy
Etiology	Etiology unknown Trauma/repeated inflammation Familial predisposition Associated with DM, vascular disease, autoimmunity, Dupuytren's contracture, erectile dysfunction, urethral instrumentation	50% idiopathic **Ischemic (common):** Thromboembolic (sickle cell) Non-Ischemic: Trauma Medications Neurogenic	Iatrogenic (post cleaning/ instrumentation) Trauma Infectious (balanitis, balanoposthitis), sexual activity	Congenital (90% natural separation by age 3) Balanitis Poor hygiene	Psychological factors Primary: no period of acceptable control Secondary: symptoms after a period of control, not associated with general medical condition
Hx/P/E	Penile curvature/ shortening Pain with erection Poor erection distal to plaque	Painful erection ± signs of necrosis Note: non-ischemic (*high flow*) priapism may present without pain	Painful, swollen glans penis, foreskin Constricting band proximal to corona Dysuria, decreased urinary stream in children	Limitation and pain when attempting to retract foreskin Balanoposthitis (infection of prepuce)	Ejaculatory latency ≥1 min Inability to control or delay ejaculation Psychological distress
Investigations	Hx and P/E	Hx and P/E Cavernosal blood gas analysis Doppler U/S of the penis	Hx and P/E	Hx and P/E	Hx and P/E Testosterone levels if in conjunction with impotence
Treatment	**Supportive measures:** PDE5 inhibitor for ED NSAID for pain **Medical management:** Traction device Intralesional verapamil Intralesional collagenase **Surgical management:** Incision/excision of plaque Plication surgery Penile prosthesis	Treat reversible causes **High-flow:** Self-limited Consider arterial embolization **Low-flow:** Needle aspirated decompression Phenylephrine intracorporeal injection q3-5 min Surgical shunt no response within 1 h	Manual pressure (with analgesia) Dorsal slit Circumcision (urgent or elective to prevent recurrence)	Proper hygiene Topical corticosteroids Dorsal slit Circumcision	Rule out medical condition Address psychiatric concerns, counselling Medication: SSRI or clomipramine Topical lidocaine-prilocaine



1. Fibrous plaque
2. Tunica albuginea
3. Corpus cavernosum
4. Buck's fascia
5. Corpus spongiosum
6. Urethra

© June Li

Figure 20. Peyronie's disease

Erectile Dysfunction

Definition
- consistent (>3 mo duration) or recurrent inability to obtain or maintain an adequate erection for satisfactory sexual performance

Physiology
- erection involves the coordination of psychologic, neurologic, hemodynamic, mechanical, and endocrine components

- nerves: sympathetic (T11-L2), parasympathetic (S2-4), somatic (dorsal penile/pudendal nerves (S2-4))
- erection ("POINT")
  - parasympathetics ➔ NO release ➔ increased cGMP within corpora cavernosa leading to:
    1. arteriolar dilatation
    2. sinusoidal smooth muscle relaxation ➔ increased arterial inflow and compression of penile venous drainage (decreased venous outflow)
- emission ("SHOOT")
  - sensory afferents from glans
  - secretions from prostate, seminal vesicles, and ejaculatory ducts enter prostatic urethra (sympathetics)
- ejaculation ("SHOOT")
  - bladder neck closure (sympathetic)
  - spasmodic contraction of bulbocavernosus and pelvic floor musculature (somatic)
- detumescence
  - sympathetic nerves, norepinephrine, endothelin-1 ➔ arteriolar and sinusoidal constriction ➔ penile flaccidity

Erections POINT AND SHOOT
parasympathetics = **point**; and sympathetics/somatics = **shoot**

Classification

Table 25. Classification of Erectile Dysfunction

	Psychogenic*	Organic*
Prevalence	Less common	More common
Onset	Sudden	Gradual
Frequency	Sporadic	All circumstances
Variation	With partner and circumstance	No
Age	Younger	Older
Organic Risk Factors (HTN, DM, dyslipidemia)	No organic risk factors	Risk factors present
Nocturnal/Morning Erection	Present	Absent

*Combination can co-exist

Etiology ("IMPOTENCE")
Iatrogenic: pelvic surgery, pelvic radiation
Mechanical: Peyronie's, post-priapism
Psychological: depression, stress, anxiety, PTSD, widower syndrome
Occlusive: arterial HTN, DM, smoking, hyperlipidemia, PVD, impaired veno-occlusion
Trauma: penile/pelvic, bicycling
Extra factors: renal failure, cirrhosis, COPD, sleep apnea, malnutrition
Neurogenic: CNS (e.g. Parkinson's, MS, spinal cord injury, Guillain-Barré, spina bifida, stroke), PNS (e.g. DM, peripheral neuropathy)
Chemical: antihypertensives, sedatives, antidepressants, antipsychotics, anxiolytics, anticholinergics, antihistamines, antiandrogens (including 5-α reductase inhibitors), statins, GnRH agonists, illicit drugs
Endocrine: DM, hypogonadism, hyperprolactinemia, hypo/hyperthyroid

Diagnosis

- complete Hx (include sexual, medical, and psychosocial aspects)
- self-administered questionnaires (e.g. International Index of Erectile Function, Sexual Health Inventory for Men Questionnaire, ED Intensity Scale, ED Impact Scale)
- focused P/E, including vascular and neurologic examinations, secondary sexual characteristics
- lab investigations, dependent on clinical picture
  - risk factor evaluation: fasting blood glucose or HbA1c, cholesterol profile
  - optional: TSH, CBC, U/A, testosterone (free and total), prolactin, LH
- specialized testing including nocturnal penile tumescence monitoring usually unnecessary
- evaluation of penile vasculature only relevant with past history of trauma (e.g.pelvic fracture)

Testosterone deficiency is an uncommon cause of ED

Treatment

- can often be managed by family physician, see sidebar for when to refer
- must fully inform patient/partner of options, benefits and complications
- non-invasive
  - lifestyle changes (alcohol, smoking, physical activity), psychological (sexual counselling and education)
  - change precipitating medications
  - treat underlying causes (DM, CVD, HTN, endocrinopathies)
- minimally invasive
  - oral medication (see *Common Medications*, U47)
    - sildenafil, tadalafil, vardenafil, avanafil (not available in Canada): inhibits PDE5 to increase intracavernosal cGMP levels
      - all four have similar effectiveness, difference in onset of action is not clinically significant
      - tadalafil has longer half-life, no cyanopsia, and can be taken on empty or full stomach
  - vacuum devices: draw blood into penis via negative pressure, then put ring at base of penis
  - MUSE: male urethral suppository for erection – vasoactive substance (PGE1) capsule inserted into urethra
- invasive
  - intracavernous vasodilator injection/self-injection
  - triple therapy (papaverine, phentolamine, PGE1), bimix (papaverine and phentolamine) or PGE1 alone
  - complications: priapism (overdose), fibrosis of tunica albuginea at site of repeated injections (Peyronie's plaque), and injection site injuries (pain, hematoma, etc.)
- surgical
  - penile implant (last resort): malleable or inflatable

PDE5 inhibitors are contraindicated in patients on nitrates/nitroglycerin due to severe hypotension

Initial trial of MUSE® or intracavernosal injection should be done under medical supervision

Penile vascular abnormalities may be a marker of risk for CV disease. Young men with vascular ED have 50x higher risk of having a CV event

Trauma

- see Emergency Medicine, ER7

Renal Trauma

Classification According to Severity
- minor
  - contusions and superficial lacerations/hematomas: 90% of all blunt traumas, surgical exploration seldom necessary
- major
  - laceration that extends into medulla and collecting system, major renal vascular injury, shattered kidney

Etiology
- 80% blunt (MVC, assaults, falls) vs. 20% penetrating (stab wounds and gunshots)

Clinical Features
- mechanism of injury raises suspicion
- can be hemodynamically unstable secondary to renal vascular injury and/or other sustained injuries: ABCs
- upper abdominal tenderness, flank tenderness, flank contusions, lower rib/vertebral transverse process fracture

Investigations
- U/A
  - hematuria: requires workup but degree does not correlate with the severity of injury
- imaging
  - CT (contrast, triphasic) if patient stable: look for renal laceration, extravasation of contrast, retroperitoneal hematoma, and associated intra-abdominal organ injury

Staging (does not necessarily correlate well with clinical status)
- I: contusion/hematoma
- II: <1 cm laceration without urinary extravasation
- III: >1 cm laceration without urinary extravasation
- IV: laceration causing urinary extravasation and/or main arterial or vein injury with contained hematoma
- V: shattered kidney or avulsion of pedicle

Treatment
- microscopic hematuria + isolated well-staged minor injuries ➔ no hospitalization
- gross hematuria + contusion/minor lacerations ➔ hospitalize, bedrest, repeat CT if bleeding persists
- surgical intervention/minimally invasive angiography and embolization (majority now managed conservatively, nonoperatively)
  - absolute indications
    - hemorrhage and hemodynamic instability
  - relative indications
    - non-viable tissue and major laceration
    - urinary extravasation
    - vascular injury
    - expanding or pulsating perirenal mass
    - laparotomy for associated injury
- follow-up with U/S or CT before discharge, and at 6 wk

Complications
- HTN in 5% of renal trauma

Bladder Trauma

Classification
- contusions: no urinary extravasation, damage to mucosa or muscularis
- intraperitoneal ruptures: often involve the bladder dome
- extraperitoneal ruptures: involve anterior or lateral bladder wall in full bladder

Etiology
- blunt (MVC, falls, and crush injury) vs. penetrating trauma to lower abdomen, pelvis, or perineum
- blunt trauma is associated with pelvic fracture in 97% of cases

Clinical Features
- abdominal tenderness, distention, peritonitis, and inability to void
- can be hemodynamically unstable secondary to pelvic fracture, other sustained injuries: ABCs
- suprapubic pain

Investigations
- U/A: gross hematuria in 90%
- imaging (including CT cystogram and post-drainage films for extravasation)

Treatment
- penetrating trauma ➔ surgical exploration
- contusion ➔ urethral catheter until hematuria completely resolves
- extraperitoneal bladder perforations ➔ typically non-operative with foley insertion, and follow with cystograms
  - surgery if: infected urine, rectal/vaginal perforation, bony spike into bladder, laparotomy for concurrent injury, bladder neck involvement, persistent urine leak, and failed conservative management
- intraperitoneal rupture usually requires surgical repair and suprapubic catheterization

Complications
- complications of bladder injury itself are rare
- mortality is around 20%, and is usually due to associated injuries rather than bladder rupture

Urethral Injuries

Etiology
- posterior urethra
  - common site of injury is junction of membranous and prostatic urethra due to blunt trauma, MVCs, pelvic fracture
  - shearing force on fixed membranous and mobile prostatic urethra
- anterior urethra
  - straddle injury can crush bulbar urethra against pubic rami
- other causes
  - iatrogenic (instrumentation, prosthesis insertion), penile fracture, masturbation with urethral manipulation
- always look for associated bladder rupture

Clinical Features
- blood at urethral meatus
- high-riding prostate on DRE
- swelling and butterfly perineal hematoma
- penile and/or scrotal hematoma
- sensation of voiding without U/O
- distended bladder

All patients with suspected urethral injury should undergo RUG

Investigations
- generally will perform RUG or cystoscopy prior to attempt at catheterization

Treatment
- simple contusions
  - no treatment
- partial urethral disruption
  - very gentle attempt at catheterization by urologist
  - with no resistance to catheterization ➔ Foley x 2-3 wk
  - with resistance to catheterization ➔ suprapubic cystostomy or urethral catheter alignment
- periodic flow rates/urethrograms to evaluate for stricture formation
- complete disruption
  - immediate repair if patient stable, delayed repair if unstable (suprapubic tube in interim)

Complications
- stricture

Infertility

Definition
- failure to conceive after 1 yr of unprotected and properly timed intercourse
- incidence
  - 15% of all couples (35-40% female, 20% male, 25-30% combined)

Female Factors

- see Gynaecology, GY23

Male Factors

Male Reproduction
- hypothalamic-pituitary-testicular axis (HPTA)
  - pulsatile GnRH from hypothalamus acts on anterior pituitary stimulating release of LH and FSH
  - LH acts on Leydig (interstitial) cells ➔ testosterone synthesis and secretion
  - FSH acts on Sertoli cells ➔ structural and metabolic support to developing spermatogenic cells
  - FSH and testosterone support germ cells (responsible for spermatogenesis)
  - sperm route: epididymis ➔ vas deferens ➔ ejaculatory ducts ➔ prostatic urethra

Etiology
- idiopathic (40-50% infertile males)
- testicular
  - varicocele (35-40% infertile males)
  - tumour
  - congenital (Klinefelter's triad: small, firm testes, gynecomastia, and azoospermia)
  - post-infectious (epididymo-orchitis, STIs, mumps)
  - uncorrected torsion
  - cryptorchidism (<5% of cases)
- obstructive
  - iatrogenic (surgery: see below)
  - infectious (gonorrhea, chlamydia)
  - trauma
  - congenital (absence of vas deferens, CF)
  - bilateral ejaculatory duct obstruction, epididymal obstructions
  - Kartagener's syndrome (autosomal recessive disorder causing defect in action of cilia)
- endocrine (see Endocrinology, E52)
- HPTA (2-3%) e.g. Kallmann's syndrome (congenital hypothalamic hypogonadism), excess prolactin, excess androgens, excess estrogens
- other
  - retrograde ejaculation secondary to surgery
  - medications
  - prior exposure to chemotherapy or pelvic radiation
  - drugs: cannabis, cocaine, tobacco, alcohol
  - increased testicular temperature (sauna, hot baths, tight pants, or underwear)
  - chronic disease: e.g. liver, renal

History
- age of both partners
- medical: past illness, DM, trauma, CF, genetic syndromes, STIs, cryptorchidism
- surgical: vasectomy, herniorrhaphy, orchidopexy, prostate surgery
- fertility: pubertal onset, previous pregnancies, duration of infertility, treatments
- sexual: libido, erection/ejaculation, timing, frequency
- FMHx
- medications: cytotoxic agents, GnRH agonists, anabolic steroids, nitrofurantoin, cimetidine, sulfasalazine, spironolactone, α-blockers
- social Hx: alcohol, tobacco, cocaine, cannabis, school performance/learning disabilities (suggestive of Klinefelter syndrome)
- occupational exposures: radiation, heavy metals

Physical Exam
- general appearance: sexual development, gynecomastia, obesity, pubic hair
- scrotal exam: size, consistency, and nodularity of testicles; palpation of cord for presence of vas deferens; DRE; valsalva for varicocele

Majority of antenatal hydronephroses resolve during pregnancy or within the first year of life

Common Terminology on SA
Teratospermia: Abnormal morphology
Asthenospermia: Abnormal motility
Oligospermia: Decreased sperm count
Azoospermia: Absent sperm in semen
Mixed types: e.g. oligoasthenospermia

Mutation of cystic fibrosis transmembrane conductance regulator (CFTR) gene is associated with congenital bilateral absence of vas deferens and epididymal cysts, even if patient manifests no symptoms of CF

WHO Guidelines
Male Infertility Factors

SPERM COUNT
Systemic factor/Smoking
Psychological illness
Endocrinopathy
Retrograde ejaculation
Medications
Chronic disease
Obstructive
Unexplained
Narcotics
Testicular

Normal Semen Values
- Volume: 1.5-7.6 mL
- Concentration: >15 million sperm/mL
- Morphology: 30% normal forms
- Motility: >40% adequate forward progression
- Liquefaction: complete in 20 min
- pH: 7.2-7.8
- WBC: <10/HPF or <106 WBC/mL semen

Hypo-gonadal patients interested in fertility preservation should be cautioned against the isolated use of exogenous testosterone and be counseled to pursue treatments that increase endogenous serum testosterone production

Investigations

- semen analysis (SA) ≥2 specimens, collected 1-2 wk apart
- hormonal evaluation
  - indicated with abnormal SA (rare to be abnormal with normal SA)
  - testosterone and FSH
  - serum LH and prolactin are measured if testosterone or FSH are abnormal
- genetic evaluation
  - chromosomal studies (Klinefelter syndrome – XXY)
  - genetic studies (Y-chromosome microdeletion, CF gene mutation)
- immunologic studies (antisperm antibodies in ejaculate and blood)
- testicular biopsy
- scrotal U/S (varicocele, testicular size)
- vasography (assess patency of vas deferens)

Treatment

- assessment of partner
- lifestyle
  - regular exercise, healthy diet
  - eliminate alcohol, tobacco, and illicit drugs
- medical
  - endocrine therapy (see Endocrinology, E54)
  - treat retrograde ejaculation
  - discontinue anti-sympathomimetic agents, may start α-adrenergic stimulation (phenylpropanolamine, pseudoephedrine, or ephedrine)
  - treat underlying infections
- surgical
  - varicocelectomy (if indicated)
  - vasovasostomy (vasectomy reversal) or epididymovasostomy
  - transurethral resection of blocked ejaculatory ducts
- assisted reproductive technologies (ART)
  - refer to infertility specialist
  - sperm washing + intrauterine insemination (IUI)
  - *in vitro* fertilization (IVF)
  - intracytoplasmic sperm injection (ICSI) after CF screening of patient and partner in patients with congenital bilateral absence of vas deferens

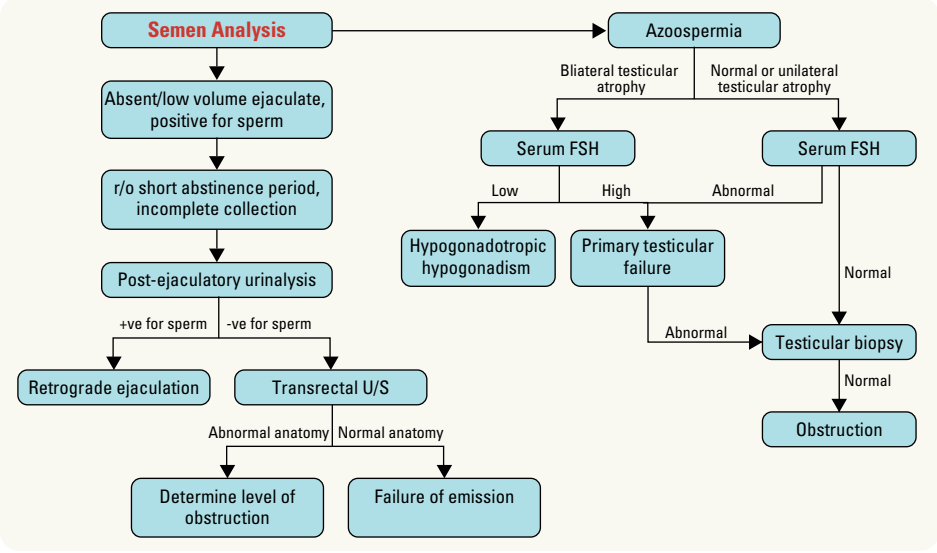


Figure 21. Infertility workup
Note: azoospermic patients with normal FSH may be assumed to be obstructive without a testicular biopsy

SFU Grading of Hydronephrosis

Grade 0
- No dilation, calyceal walls are opposed to each other
- Grade 1 (mild)
- Dilation of renal pelvis without dilation of the calyces
- No parenchymal atrophy

Grade 2 (mild)
- Dilation of renal pelvis and calyces (pelvicalyceal pattern is retained)
- No parenchymal atrophy

Grade 3 (moderate)
- Moderate dilation of renal pelvis and calyces
- Mild calyceal thinning, blunting of fornices, and flattening of papillae

Grade 4 (severe)
- Gross dilation of renal pelvis and calyces with loss of borders
- Cortical thinning

Note: SFU grading should be supplemented with UTD grading to address the shortcomings of this grading system.

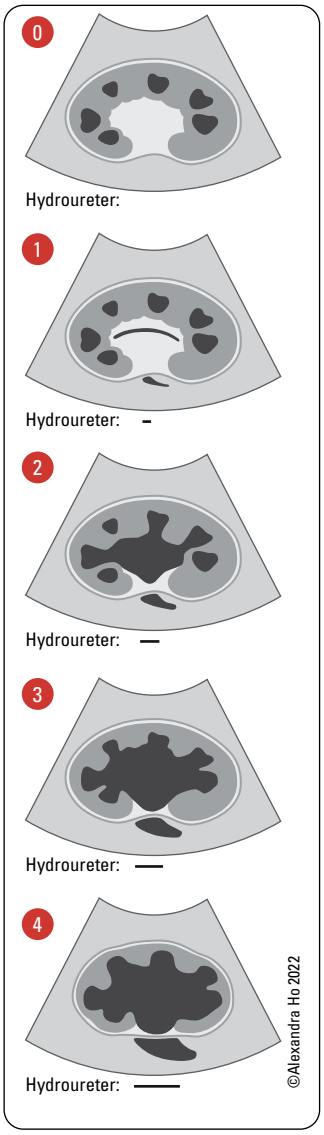

Figure 22. SFU grading (based on ultrasound)

Paediatric Urology

Congenital Abnormalities

- not uncommon; 1 in 200 have congenital abnormalities of the GU tract
- six common presentations of congenital urological abnormalities

1. ANTENATAL HYDRONEPHROSIS

Epidemiology
- 1-5% fetal U/S, some detectable as early as first trimester
- most common urological consultation in perinatal period and one of most common U/S abnormalities of pregnancy

Differential Diagnosis
- transient primary hydronephrosis
- UPJ obstruction
- VUR
- UVJ obstruction or primary non-obstructive megaureter
- ureterocele
- ectopic ureter
- causes of megacystitis (e.g. PUV, Prune Belly syndrome)

Treatment
- antenatal *in utero* intervention rarely indicated unless evidence of lower urinary tract obstruction with oligohydramnios
- ABx prophylaxis at birth to reduce UTI rates is controversial but may be beneficial to infants with high grade hydronephrosis, dilated ureter, or bladder abnormality. Commonly used ABx include: amoxicillin, cephalexin, and trimethoprim

2. POSTERIOR URETHRAL VALVES

Epidemiology
- the most common congenital obstructive urethral lesion in male infants

Pathophysiology
- abnormal mucosal folds at the distal prostatic urethra causing varying degrees of obstruction

Clinical Features
- dependent on age
  - antenatal: bilateral hydronephrosis, distended bladder, oligohydramnios
  - neonatal (recognized at birth): palpable abdominal mass (distended bladder, hydronephrosis), urinary ascites (transudation of retroperitoneal urine), respiratory distress (pulmonary hypoplasia from oligohydramnios), weak urinary stream
  - neonatal (not recognized at birth): within weeks present with urosepsis, dehydration, electrolyte abnormalities, failure to thrive; rule out pyloric stenosis, which may present similarly
  - toddlers: UTIs or voiding dysfunction
  - school-aged boys: voiding dysfunction → urinary incontinence
- associated findings include renal dysplasia and secondary VUR

Investigations
- most commonly recognized on prenatal U/S → bilateral hydronephrosis, thickened bladder, dilated posterior urethra ("keyhole sign"), oligohydramnios in a male fetus
- VCUG → dilated and elongated posterior urethra, trabeculated bladder, VUR

Treatment
- immediate catheterization to relieve obstruction, followed by cystoscopic resection of PUV when baby is stable
- if resection of PUV is not possible, vesicostomy is indicated

3. URETEROPELVIC JUNCTION OBSTRUCTION

Etiology
- unclear: adynamic ureteral segment, stenosis, strictures, extrinsic compression, aberrant blood vessels
- can rarely be secondary to tumour, stone, etc. in children

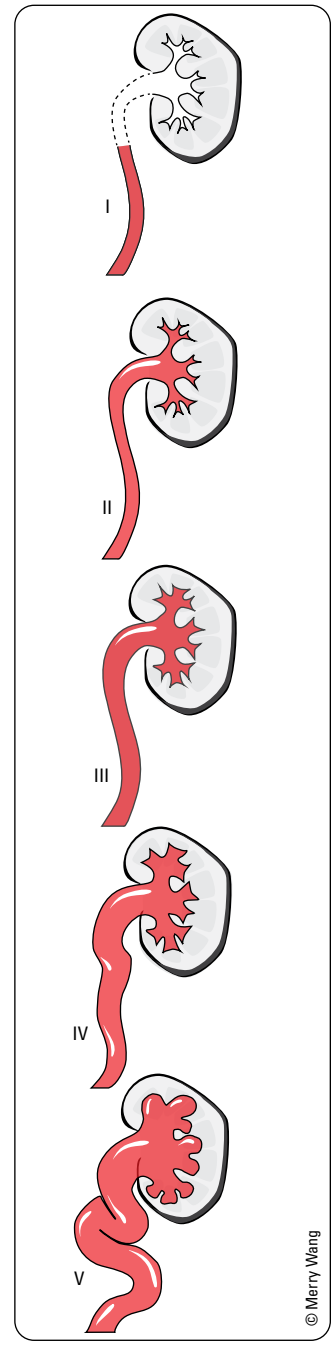

Figure 23. VUR grading
(based on cystogram)

VUR Grading (based on cystogram)
Grade I: ureters only fill
Grade II: ureters and pelvis fill
Grade III: ureters and pelvis fill with some dilatation
Grade IV: ureters, pelvis, and calyces fill with significant dilatation
Grade V: ureters, pelvis, and calyces fill with major dilatation and tortuosity

Defer circumcision in patients with hypospadias

Epidemiology
- the most common congenital defect of the ureter
- M:F=2:1
- up to 40% bilateral, which may be associated with worse prognosis

Clinical Features
- symptoms depend on severity and age at diagnosis (mostly asymptomatic finding on antenatal U/S)
  - infants: abdominal mass, urinary infection
  - children: pain, vomiting, failure to thrive
- some cases are diagnosed after puberty and into adulthood
  - in adolescents and adults, the symptoms may be triggered by episodes of increased diuresis, such as following alcohol ingestion (Dietl's crisis)

Investigations
- antenatal: serial U/S most common, and renal scan ± furosemide

Treatment
- surgical correction (pyeloplasty), consider nephrectomy if <15% differential renal function

4. VESICOURETERAL REFLUX

Definition
- retrograde passage of urine from the bladder, through the UVJ, into the ureter

Classification
- primary reflux: incompetent or inadequate closure of UVJ
  - lateral ureteral insertion, short submucosal segment
- secondary reflux: abnormally high intravesical pressure resulting in failure of UVJ closure
  - often associated with anatomic (PUV) or functional (neuropathic) bladder dysfunction

Epidemiology
- estimated ~1% of newborns, but not well known
- incidence and clinical relevance higher in children with febrile UTIs and prenatal hydronephrosis
- risk factors: race (white > black), female gender, age (<2 yr), genetic predisposition

Investigations
- focused Hx, particularly of voiding dysfunction (frequency, urgency, diurnal enuresis, constipation, encopresis)
  - also screen for infections (UTI, pyelonephritis, urosepsis) and renal failure (uremia, HTN)
- initial evaluation of renal status, growth parameters, and blood pressure is warranted in any child with VUR due to relatively high incidence of renal scarring
  - height, weight, blood pressure
  - serum Cr
  - U/A, C&S
  - renal U/S
  - DMSA renal scan if at high-risk (greater sensitivity in detecting structural defects associated with dysplasia, renal scarring, or pyelonephritis; entails radiation exposure)
  - sibling family screening is controversial

Treatment
- spontaneous resolution in 60% of primary reflux
  - in lower grades (I-III), goal is to prevent infection or renal damage via medical treatment
- medical treatment: daily ABx prophylaxis at half the treatment dose for acute infection (see Table 8, U13 - TMP/SMX, trimethoprim, amoxicillin, or nitrofurantoin)
- surgical treatment: ureteral reimplantation ± ureteroplasty, or subureteric injection with bulking agents (Deflux® or Macroplastique®)
  - indications include failure of medical management, renal scarring (e.g. renal insufficiency, HTN), breakthrough UTIs, persistent high grade (IV or V) reflux

Antimicrobial Prophylaxis for Children with Vesicoureteral Reflux
NJEM 2014;370:2367-2376
Purpose: To determine whether long-term antimicrobial prophylaxis is effective in preventing recurrences of UTI and reducing the likelihood of renal scarring.
Methods: Children with vesicoureteral reflux that were diagnosed after a first or second febrile or symptomatic UTI were randomized to either receive trimethoprim–sulfamethoxazole prophylaxis or placebo.
Results: Prophylaxis reduced the risk of recurrences by 50% and was particularly effective in children whose index infection was febrile and in those with baseline bladder and bowel dysfunction. The occurrence of renal scarring did not differ significantly between the two groups.
Conclusions: Antibiotic prophylaxis given to children with vesicoureteral reflux after a UTI resulted in a reduction of subsequent UTIs, but was not associated with reduced risk of renal scarring.

5. HYPOSPADIAS

Definition
- a condition in which the urethral meatus opens on the ventral side of the penis, proximal to the normal location in the glans penis
- depending on severity, may result in difficulty directing urinary stream, having intercourse, or depositing sperm in vagina

Epidemiology
- very common; 1 in 300 live male births
- distal hypospadias more common than proximal

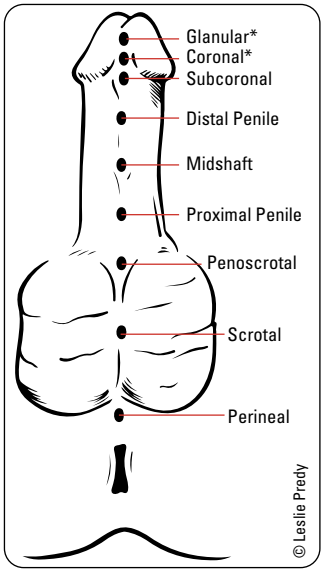

Figure 24. Classification of hypospadias
(*account for 75%)

- white >> black
- may be associated with ventral penile curvature, disorders of sexual differentiation, undescended testicles, or inguinal hernia

Treatment
- early surgical correction; optimal repair before 2 yr
- neonatal circumcision should be deferred because the foreskin may be utilized in the correction

6. EXSTROPHY-EPISPADIAS COMPLEX

Definition
- a spectrum of defects depending on the timing of the rupture of the cloacal membrane
  - bladder exstrophy: congenital defect of a portion of lower abdominal and anterior bladder wall, with exposure of the bladder lumen
  - cloacal exstrophy
    - exposed bladder and bowel with imperforate anus
    - associated with spina bifida in >50%
  - epispadias (least severe)
    - urethra opens on dorsal aspect of the penis, often associated with penile curvature

Etiology
- represents failure of closure of the cloacal membrane, resulting in the bladder and urethra opening directly through the abdominal wall

Epidemiology
- rare: incidence 1 in 30000, M:F=3:1 predominance
- high morbidity → multiple reconstructive surgeries, incontinence, infertility, reflux

Treatment
- surgical correction at birth
- later corrections for incontinence, VUR, and low bladder capacity may be needed

Nephroblastoma (Wilms' Tumour)

Etiology
- arises from abnormal proliferation of metanephric blastema

Epidemiology
- 5-10: 5% of all childhood cancers, 5% bilateral, 10% associated with congenital malformation syndromes
- most common primary malignant renal tumour of childhood
- average age of incidence is 3 yr

Associated Syndromes of Wilms' Tumour
- Wilms' aniridia genital anomaly retardation
- Beckwith-Wiedemann syndrome
- Denys-Drash syndrome

Clinical Features
- abdominal mass: large, firm, unilateral (80%)
- HTN (25%)
- flank tenderness (30-40%)
- microscopic hematuria (12-25%)
- nausea/vomiting

Treatment
- always investigate contralateral kidney and renal vein (for tumour thrombus)
- unilateral disease: radical nephrectomy ± radiation ± chemotherapy
- bilateral disease: nephron-sparing surgery following neoadjuvant chemotherapy

Prognosis
- 5 yr survival 80%

Cryptorchidism/Ectopic Testes

Definition
- abnormal location of testes somewhere along the normal path of descent (external inguinal ring > inguinal canal > abdominal)
- Denis Browne pouch (between external oblique fascia and Scarpa's fascia) most common
- differential diagnosis:
  - retractile testes
  - atrophic testes
  - disorders of sexual differentiation (bilateral impalpable gonads)

Normal Testicular Development and Descent in Utero
- **2nd mo**: Testicle begins to form
- **4th mo**: Begins to take on its normal appearance and migrates from its origin at the kidney to the internal inguinal ring
- **7th mo**: The testis, surrounded in peritoneal covering, begins to descend through the internal ring, inguinal canal, and external ring to terminate in the scrotum

Epidemiology
- 1.0-4.6% of full term newborns, increased risk in preterms
- 0.7-1.0% at 1 yr

Treatment
- orchiopexy
- hormonal therapy not proven to be of benefit over standard surgical treatment

Prognosis
- reduction in fertility
  - untreated bilateral cryptorchidism: ~100% infertility, due to Leydig and germ cell loss
  - paternity rates: 33-65%, 90%, and 93% in formerly bilateral cryptorchid, formerly unilateral cryptorchid, and normal men, respectively
- increased malignancy risk
  - intra-abdominal > inguinal
  - surgical correction facilitates testicular monitoring and may reduce malignancy risk
- increased risk of testicular torsion (reduced by surgical correction)

Disorders of Sexual Differentiation

Definition
- formerly known as intersex disorders: considered social emergency
- abnormal genitalia for chromosomal sex due to the undermasculinization of males or the virilization of females

Classification
1. 46 XY DSD
   - defect in testicular synthesis of androgens
   - androgen resistance in target tissues
   - palpable gonad
2. 46 XX DSD
   - most due to CAH (21-hydroxylase deficiency most common enzymatic defect) ➔ shunt in steroid biosynthetic pathway leading to excess androgens
   - undiagnosed and untreated CAH can be associated with life-threatening electrolyte abnormalities in the newborn (salt-wasting CAH)
3. ovotesticular DSD
4. mixed gonadal dysgenesis (46 XY/45 XO most common karyotype)
   - presence of Y chromosome ➔ partial testis determination to varying degrees

A phenotypic male newborn with bilateral non-palpable testicles should be considered 46 XX with salt-wasting CAH and must undergo proper evaluation prior to discharge

Diagnosis
- thorough FMHx noting any consanguinity
- maternal Hx, especially medication/drug use during pregnancy (maternal hyperandrogenemia)
- P/E: palpable gonad (= chromosomal male), hyperpigmentation, evidence of dehydration, HTN, stretched phallus length, position of urethral meatus
- laboratory tests
  - plasma 17-OH-progesterone (after 36 h of life) ➔ increased in CAH
  - plasma 11-deoxycortisol ➔ increased in 11-β-hydroxylase deficiency
  - basal adrenal steroid levels
  - serum testosterone and DHT pre- and post-hCG stimulation (2000 IU/d for 4 d)
  - serum electrolytes
  - chromosomal evaluation including sex karyotype
- U/S of adrenals, gonads, uterus, and fallopian tubes
- endoscopy and genitography of urogenital sinus

Treatment
- steroid supplementation as indicated (e.g. CAH)
- sex assignment after extensive family consultation
  - must consider capacity for sexually functioning genitalia in adulthood, fertility potential, and psychological impact
- reconstruction of external genitalia between 6 and 12 mo
- long-term psychological guidance and support for both patient and family

Enuresis

- see Paediatrics, P11

Bladder and Bowel Dysfunction

Definition
- bladder and bowel dysfunction (BBD) describes voiding and defecation symptoms without a neurogenic or anatomic cause

Clinical Features
- storage symptoms (urgency, frequency, urge incontinence)
- voiding symptoms (hesitancy, slow flow, intermittency)
- gastrointestinal symptoms (constipation and encopresis)

Treatment
- urotherapy and bladder retraining
- pelvic floor physiotherapy
- anticholinergics (solifenacin, propiverine, tolterodine)
- neuromodulation via transcutaneous electrical nerve stimulation

Selected Urological Procedures

Bladder Catheterization

- catheter size measured by the French (Fr) scale – circumference in mm (30 Fr = 1 cm diameter)
- each 1 mm increase in diameter = approximately 3 Fr increase (standard size 14-18 Fr)
- should be removed as soon as possible to reduce the risk of UTI

Continuous Catheterization
- indications
  - accurate monitoring of U/O
  - relief of urinary retention due to medication, neurogenic bladder, or intravesical obstruction
  - temporary therapy for urinary incontinence
  - perineal wounds
  - clot prevention (22-24 Fr) for CBI
  - intra- and postoperative
  - comfort for end of life care

Alternatives to Continuous Catheterization
- intermittent catheterization
  - PVR measurement
  - to obtain sterile diagnostic specimens for U/A, urine C&S
  - management of neurogenic bladder or chronic urinary retention
- condom catheter
- suprapubic catheter

Causes of Difficult Catheterizations and Treatment
- patient discomfort ➔ use sufficient lubrication (± xylocaine)
- collapsing catheter ➔ lubrication as above ± firmer or larger catheter (silastic catheter)
- meatal/urethral stricture ➔ dilate with progressively larger catheters/balloon catheter
- traumatic injury: repeated prior attempts at catheterization have created traumatic false passage
- BPH ➔ use Coudé catheter as angled tip can help navigate around enlarged prostate (always angle up/anteriorly)
- urethral disruption/obstruction ➔ filiform and followers or suprapubic catheterization
- anxious patient ➔ anxiolytic medication

Complications of Catheterization
- infection: UTI, bladder fistula, bladder perforation (rare)
- meatal/urethral trauma

Contraindications
- trauma: blood at the urinary meatus, scrotal hematoma, pelvic fracture, and/or high riding prostate

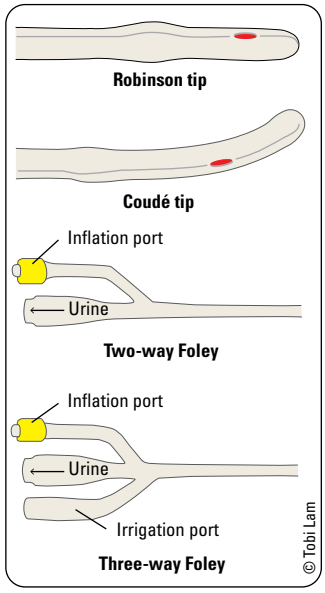

Figure 25. Transurethral (Foley) catheters

Circumcision

Definition
- removal of some or all of the foreskin from the penis

Epidemiology
- 30% worldwide
- frequency varies with geography, religious affiliation, socioeconomic status

Medical Indications
- pathological phimosis and recurrent paraphimosis
- recurrent UTIs (particularly in infants and in association with other urinary abnormalities)
- balanitis xerotica obliterans or other chronic inflammatory conditions

Contraindications
- unstable or sick infant
- congenital genital abnormalities (hypospadias, epispadias, penoscrotal webbing, concealed penis, ventral curvature); may need foreskin to aid in reconstruction
- FMHx of bleeding disorders warrants investigation prior to circumcision

Complications
- early: bleeding, infection, glans injury, amputation, slippage of circumcision device, rarely death
- late: redundant foreskin, cosmetic issues, inclusion cysts, adhesions/skin bridges, suture sinus tracts, ventral curvature, secondary buried penis, phimosis, fistula, meatal stenosis
- 0.6-2% complication rate

Vasectomy

Objective
- permanent form of contraception with high probability of reversibility
- no-scalpel vasectomy has lower risks of early postoperative complications than conventional vasectomy
- fascial interposition and cautery of the vas deferens reduce risk of contraceptive failure
- post-vasectomy semen analyses at approximately 3 and 4 mo
- other contraceptive methods should be used post-vasectomy until one azoospermic ejaculate or two consecutive ejaculates with <100000 immotile spermatozoa

Indications
- fully informed patient desiring permanent surgical sterilization

Complications
- early: infection (0.2-1.5%), bleeding or hematoma (4-20%), primary surgical failure due to recanalization or technical failure (0.2-5%)
- late: chronic scrotal pain (1-14%), delayed vasectomy failure (0.05-1%)
- risk of pregnancy after vasectomy is ~0.1%

Cystoscopy

Objective
- endoscopic inspection of the lower urinary tract (urethra, prostate, bladder, and ureteral orifices), samples for cytology
- scopes can be flexible or rigid
- done under local anesthesia only for vast majority, with no special preparation needed (no NPO, no antibiotics)

Indications
- hematuria
- LUTS (storage or voiding)
- urethral and bladder neck strictures
- bladder stones
- bladder tumour surveillance
- evaluation of upper tracts with retrograde pyelography (ureteric stents, catheters)

Newborn Male Circumcision
Paediatr Child Health 2015;20:311-315
Study: Position Statement by the Canadian Paediatric Society (CPS) reaffirmed Feb 28, 2018
Recommendations: With the exception of some high-risk populations and circumstances where circumcision is indicated for disease prevention, reduction and/or treatment, the routine circumcision of every newborn male is not recommended.

Male Circumcision for Prevention of Heterosexual Acquisition of HIV in Men
Cochrane DB Syst Rev 2009;2:CD003362
Purpose: To evaluate the effectiveness and safety of male circumcision for preventing acquisition of HIV in heterosexual men.
Methods: The analyzed data is from three randomized controlled trials to assess the efficacy of male circumcision for preventing HIV acquisition in men in Africa.
Results: Medical male circumcision reduces the acquisition of HIV by heterosexual men (38-66% over 24 mo).

Laparoscopic and Robotic-Assisted vs. Open Radical Prostatectomy for the Treatment of Localised Prostate Cancer
Cochrane DB Syst Rev 2017;9:CD009625
Purpose: To compare the effects of laparoscopic radical prostatectomy (LRP) and robotic-assisted radical prostatectomy (RARP) to the retropubic open radical prostatectomy (ORP) in men with localised prostate cancer.
Methods: The review identified two unique RCTs with direct comparison of LRP and RARP to ORP in 446 patients.
Results: When compared to ORP, urinary and sexual quality of life related outcomes appear similar for LRP and RARP. Men who undergo LRP and RARP may have shorter hospital stay (MD-.72, 95% CI -2.19 to -1.25) and require fewer blood transfusions (RR 0.24, 95% CI: 0.12-0.46). The intra- and postoperative complication rates appear similar.
Conclusions: Although there is no high-quality evidence to compare LRP and RARP to ORP in terms of oncological outcomes, patients undergoing LRP or RARP may receive fewer blood transfusions and have shorter hospital stays. The interventions did not differ in terms of urinary and sexual quality of life-related outcomes and serious postoperative complication rates.

Complications
- during procedure (very rare)
  - bleeding
  - anesthetic-related
  - perforation (rare)
- post-procedure (short-term)
  - infections (antibiotic prophylaxis recommended only for high-risk, immunosuppressed)
  - urinary retention
- post-procedure (long-term)
  - stricture

Radical Prostatectomy

Objective
- the removal of the entire prostate and prostatic capsule via a lower midline abdominal incision, laparoscopically, or robotically
  - open surgery is extraperitoneal, minimally-invasive surgery is usually intraperitoneal approach
  - internal iliac and obturator lymph nodes may also be dissected and sent for pathology (dependent on risk: clinical stage, grade, PSA)
  - seminal vesicles are also partially or completely removed

Indications
- treatment for localized prostate cancer
  - sometimes done concurrently with radical cystectomy for locally advanced bladder cancer

Complications
- immediate (intraoperative)
  - blood loss
  - rectal injury (extremely rare)
  - ureteral injury (extremely rare)
  - obturator nerve injury (extremely rare)
- perioperative
  - lymphocele formation (if concurrent pelvic lymphadenectomy performed)
  - blood loss
  - urine leak from anastomosis
- late
  - moderate to severe stress urinary incontinence (3-10%)
  - mild stress urinary incontinence (20-30%)
  - ED (~30-50%, depending on whether one, both, or neither of the neurovascular bundles are involved in extracapsular extension of tumour)

Transurethral Resection of the Prostate

Objective
- to partially resect the periurethral portion of the prostate (transition zone) to decrease symptoms of urinary tract obstruction
- accomplished via a transurethral (cystoscopic) approach using an electrocautery loop, irrigation (glycine), and illumination
- not a cancer operation
  - standard TURP done with electrocautery; newer surgical options for BPH include green-light laser photovaporization, bipolar ablation, water-vapour therapy (Rezume)

Indications
- obstructive uropathy (large bladder diverticula, renal insufficiency)
- refractory urinary retention
- recurrent UTIs
- recurrent gross hematuria
- bladder stones
- intolerance/failure of medical therapy

Complications
- acute
  - intra- or extraperitoneal rupture of the bladder
  - rectal perforation
  - incontinence
  - incision of the ureteral orifice (with subsequent reflux or ureteral stricture)
  - hemorrhage
  - epididymitis
  - sepsis

  - transurethral resection syndrome (also called "post-TURP syndrome")
    - caused by absorption of a large volume of the hypotonic irrigation solution used, usually through perforated venous sinusoids, leading to a hypervolemic hyponatremic state
    - characterized by dilutional hyponatremia, confusion, nausea, vomiting, HTN, bradycardia, visual disturbances, CHF, and pulmonary edema
    - treat with diuresis and (if severe) hypertonic saline administration
- chronic
  - retrograde ejaculation (>75%)
  - ED (5-10% risk increases with increasing use of cautery)
  - incontinence (<1%)
  - urethral stricture
  - bladder neck contracture

Extracorporeal Shock Wave Lithotripsy

Objective
- to treat renal and ureteral calculi (proximal, middle, or distal) which cannot pass through the urinary tract naturally
  - usually performed under sedation only; no internal instrumentation required; least invasive treatment option but also least successful
- shockwaves focused onto stone ➔ fragmentation, allowing stone fragments to pass spontaneously and less painfully

Indications
- potential first-line therapy for renal <1.5 cm and ureteral calculi
- individuals with calculi in solitary kidney (consider stenting kidney to prevent obstruction)
- patient preference and wait-times play a large role in stone management
  - performed under fluoroscopic-guidance, so stone needs to be radio-opaque (i.e. NOT for uric acid stones)

Contraindications
- acute UTI or urosepsis
- bleeding disorder or coagulopathy
- pregnancy
- uncontrolled HTN
- obstruction distal to stone (SWL can be used after stent or nephrostomy inserted)
  - not a contraindication but SWL less successful for very dense stones and in obese patients

Complications
- bacteriuria
- bacteremia
- post-procedure hematuria (common to have mild gross hematuria)
- ureteric obstruction (by stone fragments)
- peri-nephric hematoma

Transition-Related Surgeries

- ensure appropriate use of gender pronouns
- some procedures require 1 yr trial of hormone therapy, preoperative letters of evaluation and documentation from mental health professionals as outlined by the World Professional Association for Transgender Health Standards of Care – Version 7 guidelines

Table 26. Surgical Options for Gender Transition (Also known as Gender Affirmation Surgery)

Procedure	Description	Follow-Up
Orchiectomy	Scrotal incision and removal of bilateral testicles Scrotectomy in some patients	Eliminates need for testosterone blockers Allows for tuck with great ease
Penile Inversion Vaginoplasty	Formation of vaginal cavity and vulva (clitoris, urethra, mons, labia) using penile and scrotal skin	Lubrication required for penetration Prostate exams conducted vaginally Regular dilation of vaginal cavity to avoid stenosis Complications: granulation tissue, urinary symptoms, fistula formation, hair growth in neovagina
Radial Forearm Phalloplasty Most common technique for phallic reconstruction	Formation of penis using radial forearm graft of skin, blood vessels and nerves Urethral extension ± future penile and testicular implants	High complication rates related to urethral connection (urethral fistula, stricture, post-void dribbling/stream spraying, urinary retention), skin complications and implant issues
Anterolateral Thigh (ALT) Phalloplasty	Formation of penis using skin, blood vessels, nerves and muscular tissue from thigh Urethral extension ± future penile and testicular implants	High complication rate as above Pedicle flap failure very rare Phallus may be very thick due to subcutaneous fat of thigh Sensory recovery may be poorer than radial arm flap
Metoidioplasty	Formation of a penis through release of hormonally-enlarged clitoris from surrounding ligaments Girth added from neighbouring tissue ± urethroplasty ± vaginectomy and scrotoplasty	Lower complication rates when compared to phalloplasty Not capable of penetrative intercourse Major complications may require revision surgery: urethral strictures, urethral fistulas

Common Medications

Table 27. Erectile Dysfunction Medications

Drug	Class	Mechanism	Adverse Effects
sildenafil tadalafil vardenafil (PDE5s for use when some erection present)	Phosphodiesterase 5 inhibitor	Selective inhibition of PDE5 (enzyme which degrades cGMP) Leads to sinusoidal smooth muscle relaxation, increased blood flow and erection	Severe hypotension (very rare) Flushing, headaches, dyspepsia Contraindicated if Hx of priapism, or in conditions predisposing to priapism (leukemia, myelofibrosis, polycythemia, sickle cell disease) Contraindicated with nitrates
alprostadil (MUSE®), PGE_1 + phentolamine + papaverine mixture	Prostaglandin E_1	Activation of cAMP, relaxing sinusoidal smooth muscle Local release (urethral suppository)	Penile pain Presyncope
alprostadil, papaverine (intracavernosal injection) triple therapy also used: papaverine, phentolamine, PGE_1	See above	See above	Thickening of tunica albuginea at site of repeated injections (Peyronie's plaque) Painful erection Hematoma Contraindicated if Hx of priapism, or in high-risk of priapism

Table 28. Benign Prostatic Hyperplasia Medications

Drug	Class	Mechanism	Adverse Effects
terazosin doxazosin	α_1 blockers	α-adrenergic antagonists reduce stromal smooth muscle tone Reduce dynamic component of bladder outlet obstruction	Presyncope Leg edema Retrograde ejaculation Headache Asthenia Nasal congestion
tamsulosin alfuzosin silodosin	α_{1A} selective		
finasteride dutasteride	5-α reductase inhibitor	Blocks conversion of testosterone to DHT Reduces static component of bladder outlet obstruction Reduces prostatic volume	Sexual dysfunction PSA decreases

Table 29. Prostatic Carcinoma Medications (N>0, M>0)

Drug	Class	Mechanism	Adverse Effects
leuprolide, goserelin *"androgen deprivation therapy"*	GnRH agonist	Initially stimulates LH, increasing testosterone and causing "flare" (initially increases bone pain) Later causes low testosterone	Hot flashes Headache Decreased libido
degarelix	GnRH antagonist	Competitively binds to the pituitary gland GnRH receptors, thereby reducing the release of LH, FSH and consequently testosterone by testes	Back pain Breast enlargement Decreased libido Hot flashes Headache *Slow* or fast heartbeat
*cyproterone acetate	Steroidal antiandrogen	Competes with DHT for intracellular receptors: 1. Prevent flare produced by GnRH agonist 2. Use for complete androgen blockade 3. May preserve potency	
flutamide, bicalutamide	Non-steroidal antiandrogen	As above	Hepatotoxic: AST/ALT monitoring
abiraterone	Non-steroidal antiandrogen	Irreversible cytochrome P450 (CYP) 17 inhibition, blocking synthesis of androgens in tumour, testis, and adrenal glands	Adrenal insufficiency (concurrent treatment with steroids often required) Hypertriglyceridemia Peripheral edema
enzalutamide	Non-steroidal antiandrogen	Androgen receptor signaling inhibitor (full antagonist)	Peripheral edema Fatigue and weakness Hot flashes

*Very rarely used

Table 30. Continence Agents and Overactive Bladder Medications

Drug	Class	Mechanism	Indication	Adverse Effects
oxybutynin	Antispasmodic	Inhibits action of acetylcholine on smooth muscle Decreases frequency of uninhibited detrusor contraction Diminishes initial urge to void	Overactive bladder Urge incontinence + urgency + frequency	Dry mouth Blurred vision Constipation Supraventricular tachycardia
oxybutynin tolterodine trospium solifenacin darifenacin fesoterodine propiverine	Anticholinergic	β-sympathetic receptor blocker in the bladder; relaxes bladder during storage phase	Overactive bladder Urge incontinence + urgency + frequency	As above
mirabegron	β_3 agonist	Sympathomimetic effects: Urinary sphincter contraction Anticholinergic effects: Detrusor relaxation	Overactive bladder Urge incontinence + urgency + frequency	Blood pressure should be monitored
imipramine	Tricyclic antidepressant	Prevents the release of neurotransmitters	Stress and urge incontinence	As above Weight gain Orthostatic hypotension Prolonged PR interval
Botulinum toxin A bladder injections	Neurotoxin	Prevents the release of neurotransmitters	Refractory OAB incontinence both neurogenic and non-neurogenic	Urinary retention, UTI

Note: All anticholinergics are equally effective and long-acting formulations are better tolerated. Newer muscarinic M3 receptor specific agents (solifenacin, darifenacin) are equally efficacious as older drugs, however, RCTs based on head-to-head comparison to long acting formulations are lacking

Landmark Urology Trials

Trial Name	Reference	Clinical Trial Details
BENIGN PROSTATIC HYPERPLASIA		
PCPT	N Engl J Med 2003;349:215-224	**Title**: The Influence of Finasteride on the Development of Prostate Cancer **Purpose**: To determine whether the drug Finasteride (5-alpha reductase inhibitor) could prevent prostate cancer in men ages 55 and older. **Methods**: 18882 men 55 yr or older with a normal digital rectal examination and a (PSA) level equal to or less than 3.0 ng per milliliter were randomly to receive finasteride (5 mg per day) or placebo for 7 yr. **Results**: There was a 24.8% reduction in prostate cancer prevalence over the 7-yr period among the Finasteride arm compared to the placebo arm (95 % confidence interval, 18.6 to 30.6 percent; P<0.001).However there was a significant increase in high-grade disease among men in the finasteride group compared to the placebo (6.4 % vs 5.1% P=0.005). **Conclusion**: The PCPT trial in 2003 was the first study to show that a medication (Finasteride) reduces the likelihood of developing prostate cancer. Upon long term follow-up in 2013, this reduction in risk has been attributed to less likelihood of low-grade cancers in men taking finasteride. Although participants who developed prostate cancer while taking finasteride were more likely to have high-grade cancers, this increase was attributed to better detection of disease rather than medication use.

Trial Name	Reference	Clinical Trial Details
MTOPS	NJEM 2003;349:2387-2398	**Title**: The Long-Term Effect of Doxazosin, Finasteride, and Combination Therapy on the Clinical Progression of Benign Prostatic Hyperplasia **Purpose**: To determine whether therapy with doxazosin (α-blocker) or finasteride (5α-reductase inhibitor), alone or in combination, would delay or prevent clinical progression of benign prostatic hyperplasia (BPH). **Methods**: Participants were followed-up for a mean time of 4.5 yr to compare the effects of the interventions. The primary outcome was overall clinical progression of BPH (≥4 points from baseline in AUA symptoms score, acute urinary retention, urinary incontinence, renal insufficiency, or recurrent UTI). Results: The risk of overall clinical progression was significantly reduced by doxazosin (39% risk reduction, P<0.001) and finasteride (34% risk reduction, P=0.002), as compared with placebo, and the risk was reduced even more with combination therapy (66% for the comparison with placebo, P<0.001) compared with doxazosin (P<0.001) or finasteride (P<0.001) alone. **Conclusions**: Long-term combination therapy with doxazosin and finasteride reduced the clinical progression of BPH significantly more than each therapy alone, as well as reduce the need for invasive therapy in the long term.
BLADDER CARCINOMA		
Neoadjuvant Chemotherapy plus Cystectomy Compared with Cystectomy Alone for Locally Advanced Bladder Cancer	NEJM 2003;349:859-866	**Title**: Neoadjuvant Chemotherapy plus Cystectomy Compared with Cystectomy Alone for Locally Advanced Bladder Cancer **Purpose**: To evaluate whether the addition of neoadjuvant chemotherapy to radical cystectomy improves outcomes in patients with locally advanced bladder cancer. **Methods**: 317 patients with transitional-cell carcinoma of the bladder (T2N0M0 to T4aN0M0) were randomized to undergo radical cystectomy or to receive three cycles of combined chemotherapy followed by radical cystectomy. **Results**: At 5 yr after treatment initiation, 57% of the combination-therapy group vs. 43% of the cystectomy group were alive (P=0.06). In the combination-therapy group, 38% of the patients were pathologically free of cancer at the time of cystectomy vs. 15% of the cystectomy-only group at the time of surgery (P<0.001). **Conclusions**: For locally advanced bladder carcinoma, neoadjuvant chemotherapy significantly reduces tumour volume which is associated with improved survival.
PROSTATE CANCER		
10 Yr Outcomes After Monitoring, Surgery, or Radiotherapy for Localized Prostate Cancer	NEJM 2016;375(15):1415-1424	**Title**: 10 Yr Outcomes After Monitoring, Surgery, or Radiotherapy for Localized Prostate Cancer **Purpose**: To evaluate the effectiveness of active monitoring, radical prostatectomy, and radiotherapy in relation to mortality and the incidence of metastases and disease progression. **Methods**: 1643 men randomized into active monitoring, surgery, and radiotherapy. The primary outcome was prostate-cancer mortality at median 10 yr of follow-up and the secondary outcomes were rate of disease progression, metastases, and all-cause deaths. **Results**: No significant difference among groups in prostate-cancer-specific deaths and in the numbers of deaths from any cause. Metastases developed more in the active monitoring group (33 men) vs. surgery group (13 men) or radiotherapy group (16 men) (P=0.004). Higher rates of disease progression in active-monitoring group (112 events) vs. surgery group (46 events) or radiotherapy group (46 events) (P<0.001). **Conclusions**: At 10 yr, prostate-cancer-specific mortality was low regardless of the treatment, with no significant difference among treatments. Surgery and radiotherapy were associated with lower incidences of disease progression and metastasis compared to active monitoring.
ERSPC	NJEM 2009;360:1320-1328	**Title**: Screening and Prostate-Cancer Mortality in a Randomized European Study **Purpose**: To determine the reduction of prostate-cancer mortality by PSA-based screening. **Methods**: Participants were randomized to a group that received PSA screening an average of once every 4 yr or to a control group that did not receive such screening. The primary outcome was the rate of death from prostate cancer. **Results**: The incidence of prostate cancer was higher in the screening group than in the control group (8.2% vs. 4.2%). The absolute risk difference was 0.71 deaths/1000 men, meaning that 1410 men would need to be screened and 48 additional cases of prostate cancer would need to be treated to prevent one death from prostate cancer. **Conclusions**: PSA-based screening reduced the rate of mortality from prostate cancer by 20% but was associated with a high risk of overdiagnosis.
CHAARTED	NJEM 2015;373(8):737-46	**Title**: Chemohormonal Therapy in Metastatic Hormone-Sensitive Prostate Cancer **Purpose**: To assess whether concomitant treatment with Androgen-deprivation therapy (ADT) plus docetaxel would result in longer overall survival than that with ADT alone. **Methods**: Patients with metastatic, hormone-sensitive prostate cancer were randomized to receive either ADT plus docetaxel or ADT alone. The primary objective was overall survival. **Results**: After a median follow-up of 28.9 months, the median overall survival was 13.6 months longer in the combination therapy group than within the ADT-alone group (P<0.001). The median time to progression was 20.2 months in the combination group and 11.7 months in the ADT-alone group (P<0.001). **Conclusions**: Combination of docetaxel and ADT for hormone-sensitive metastatic prostate cancer resulted in significantly longer overall survival than that with ADT alone.

Acronyms

AAA	abdominal aortic aneurysm
ABI	ankle-brachial index
ACEI	angiotensin converting enzyme inhibitor
AKI	acute kidney injury
ALI	acute limb ischemia
ARB	angiotensin II receptor blocker
BMT	best medical therapy
CAS	carotid artery angioplasty + stenting
CCB	calcium channel blocker
CEA	carotid endarterectomy
CEAP	clinical, etiological, anatomical, pathophysiological (classification of venous disease)
CLTI	chronic limb threatening ischemia
CTA	computed tomography angiography
CVA	cerebrovascular accident
CVD	cerebrovascular disease
CVI	chronic venous insufficiency
DIC	disseminated intravascular coagulation
DVT	deep vein thrombosis
DUS	duplex U/S
Echo	echocardiogram
EVAR	endovascular aortic aneurysm repair
HITT	heparin-induced thrombocytopenia with thrombosis
INR	international normalized ratio
LDL-C	low-density lipoprotein cholesterol
LV	left ventricular
MRA	magnetic resonance angiography
MSK	musculoskeletal
PAD	peripheral arterial disease
PT	prothrombin time
PTT	partial thromboplastin time (i.e. aPTT)
TAA	thoracic aortic aneurysm
TBI	toe-brachial index
TEE	transesophageal echocardiography
TEVAR	thoracic endovascular aortic repair
TIA	transient ischemic attack

Arterial Disease

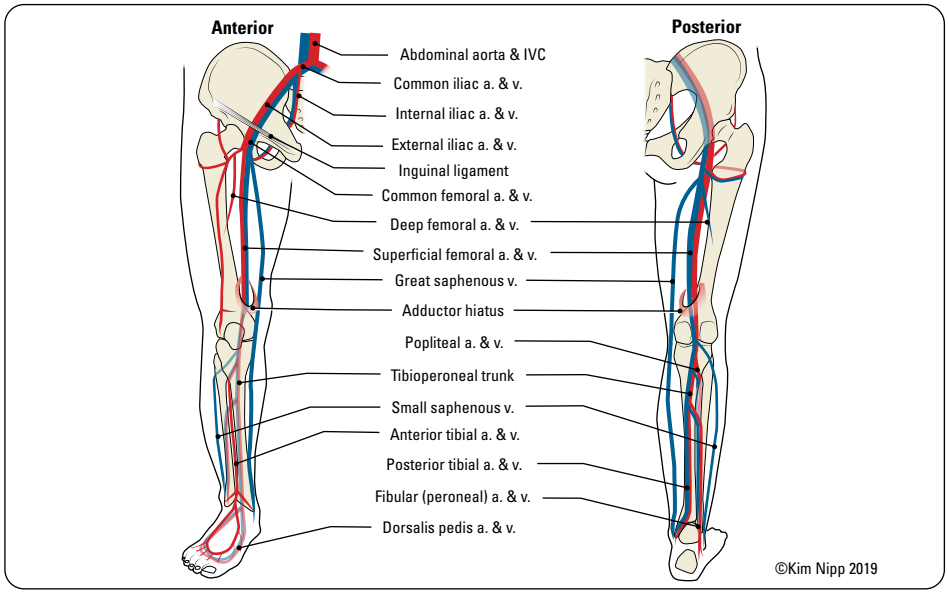

Figure 1. Peripheral vascular anatomy

Acute Limb Ischemia

Definition

- acute occlusion of a peripheral artery that often threatens limb viability
  - urgent management required as skeletal muscle can tolerate 6 h of total ischemia before irreversible damage
  - exception is acute-on-chronic occlusion, where previously developed collaterals provide minimal perfusion
- tends to be lower extremity > upper extremity; femoropopliteal > aortoiliac
- paralysis with complete loss of sensation is sign of late ischemia

Etiology and Risk Factors

- embolism
  - cardiac: arrhythmias (most common cause with atrial fibrillation), endocarditis, MI, LV aneurysm, myxoma/cardiac tumour, paradoxical embolism, valvular heart disease (including endocarditis)
  - non-cardiac: mural thrombus within arterial aneurysms, atheroembolism, ulcerated plaque with distal embolism
- thrombosis (*in situ*)
  - progression of high-grade atherosclerotic plaque to acute occlusion
  - bypass graft occlusion (most common etiology of arterial thrombosis in setting of previous open or endovascular reconstruction)
  - hypercoagulable states
    - hypercoagulability, low arterial flow, or hyperviscosity
    - HITT

  - aortic or arterial dissection
    - aortic dissection typically caused by hypertensive crisis
    - isolated arterial dissection of vessels supplying lower limbs is uncommon but can occur from trauma or collagen disorders
  - trauma (e.g. arterial transection, compression)
  - vasospasm/vasculitis
  - iatrogenic (e.g. occlusion at arterial access site)
- differentiating between embolism and thrombosis
  - embolism is more common than thrombosis
  - embolus typically lodges at arterial bifurcations, where the vessel narrows naturally
  - embolism due to plaque rupture generally results in greater degree of ischemia due to relative lack of collaterals
- suspect embolism in patients with the following features:
  - acute onset (patient able to accurately recall the moment of the event)
  - history of embolism
  - known embolic source (e.g. cardiac arrhythmias), lapse in prescribed anticoagulation
  - no prior history of intermittent claudication
  - normal pulse and Doppler U/S or DUS in unaffected limb
- suspect in-situ thrombus in patients with the following features:
  - prior history of intermittent claudication
  - prior vascular intervention/bypass
  - abnormal pulse examination of the unaffected limb

Virschow's Triad
- Hypercoagulability
- Stasis of flow
- Endothelial injury

Clinical Features

- **6 Ps** – may not all be present
  - **P**olar/**P**oikilothermia: cold
    - leg becomes cold
  - **P**allor: pale
    - within a few h becomes mottled cyanosis
  - **P**ain
    - may be constant or elicited by passive movement
    - absent in 20% of cases
  - **P**ulselessness
    - helpful to determine site of occlusion
  - **P**aresthesia (late sign of ischemia)
    - light touch lost first then other sensory modalities
  - **P**aralysis/**P**ower loss (late sign of ischemia):
    - most important; heralds impending non-salvageable limb

Hypercoagulable States

Congenital
- Group I (reduced anticoagulants)
  - Antithrombin
  - Protein C
  - Protein S
- Group II (increased coagulants)
  - Factor V Leiden
  - Prothrombin
  - Factor VIII
- Other
  - Sickle cell disease
  - Hyperhomocysteinemia

Acquired
- Age
- Obesity
- Smoking
- Immobility
- Cancer
- Pregnancy/systemic hormonal contraceptives
- Antiphospholipid antibody syndrome
- Inflammatory disorders
- Myeloproliferative disorders
- Nephrotic syndrome (acquired deficit in Protein C and S)

Investigations

- history and physical exam are essential: depending on degree of ischemia one may have to forego investigations and go straight to the OR (i.e. an immediately threatened limb)
- DUS: bilateral ultrasound examination; greater accuracy than pulse examination alone; absent arterial signal indicates threatened limb
- determine Rutherford classification (see Table 1, VS4) based on physical findings and Doppler U/S or DUS signals
- ABI: extension of physical exam, easily performed at bedside
- ECG, troponin: rule out recent MI or arrhythmia
- CBC: rule out leukocytosis, thrombocytosis, or thrombocytopenia in patients receiving heparin (may suggest HITT)
- PT/INR, PTT: patient anticoagulated/sub-therapeutic INR
- echo: identify wall motion abnormalities, intracardiac thrombus, valvular disease, or aortic dissection (Type A) (see *Aortic Dissection*, VS6)
- CTA: identify underlying atherosclerosis, aneurysm, aortic dissection; embolic source; other end organs with emboli (e.g. splenic/renal infarcts); identify level of the occlusion and extent
- angiography: can be obtained in OR as part of intervention or for treatment

Table 1. Rutherford ALI Classification

Category	Description/ Prognosis	Findings		Doppler Signals	
		Sensory Loss	Muscle Weakness	Arterial	Venous
I Viable	Not immediately threatened	None	None	Audible	Audible
II Threatened					
IIa Marginally	Salvageable if promptly treated	Minimal (toes) or none	None	Inaudible	Audible
IIb Immediately	Salvageable with immediate revascularization	More than toes, associated with rest pain	Mild, moderate	Inaudible	Audible
III Irreversible	Major tissue loss or permanent nerve damage inevitable	Profound, anesthetic	Profound, paralysis (rigor)	Inaudible	Inaudible

Adapted from: Rutherford RB, Baker JD, Ernst C, et al. Recommended standards for reports dealing with lower extremity ischemia: revised version. J Vasc Surg. 1997;26:517-38.

Treatment
- immediate heparinization with weight-based bolus (70-100 IU/kg) and continuous infusion to titrate PTT to 70-90
- IV fluids, urine output monitoring, analgesia, supplemental O_2
- if impaired neurovascular status: emergent revascularization (Rutherford category IIb)
- if intact neurovascular status: may have time for workup (including CTA)
- identify and treat underlying cause
  - embolus: embolectomy
  - thrombus: thrombectomy ± bypass graft ± endovascular therapy
  - irreversible ischemia (i.e. Rutherford category III): primary amputation or palliation
  - arterial aneurysm: bypass/stent graft
- continue heparin postoperatively; start oral anticoagulant postoperatively when stable x3 mo or longer depending on underlying etiology and other comorbidities

Complications
- local: compartment syndrome secondary to reperfusion (see Orthopaedic Surgery, OR10) with prolonged ischemia; requires 4-compartment (anterior/lateral/superficial and deep posterior) fasciotomy in calf
- heart: risk of arrhythmia, MI, cardiac arrest, and death with reperfusion injury
- kidneys/other organs: renal failure and multi-organ failure due to toxic metabolites from ischemic muscle, rhabdomyolysis
- up to 10% chance of metachronous embolism

Prognosis
- 12-15% mortality rate
- 5-40% morbidity rate (amputation)

Peripheral Arterial Disease

Definition
- chronic ischemia due to inadequate arterial supply to meet cellular metabolic demands during walking (claudication) or at rest (CLTI)

Etiology and Risk Factors
- predominantly due to atherosclerosis (for pathogenesis, see Cardiology and Cardiac Surgery, C30); primarily occurs in the lower extremities
- modifiable risk factors: smoking, DM, hyperlipidemia, HTN, obesity, and sedentary lifestyle
- non-modifiable risk factors: advanced age, and PMHx or FMHx of PAD/CAD/CVD

Clinical Features
- claudication:
  1. pain with exertion: usually in calves or any exercising muscle group
  2. relieved by short rest: less than 5 min and no postural changes necessary
  3. reproducible: same distance or time to elicit pain, same location of pain, same amount of rest to relieve pain
     - the presence of the preceding features differentiates vascular claudication from neurogenic claudication or MSK pain
- CLTI:
  1. includes rest pain, night pain, and/or tissue loss (ulceration or gangrene) in a patient with existing PAD for at least 2 wk
  2. pain most commonly over the forefoot/toes, waking person from sleep, and often relieved by hanging foot off bed

Distinction between CLTI and ALI

ALI: A precipitous decrease and/or cessation in blood flow to a limb threatening viability. Typically, due to arterial embolism or thrombosis, or other acute cause. Characterized by rapidly worsening leg pain that is present for <2 wk (usually h to d) in patients with no history of claudication

CLTI: Severe manifestation of PAD where blood flow to the extremities is markedly reduced. Defined as ischemic foot pain at rest or at night, occurring >2 wk, wounds, or gangrene in patients who may have a history of claudication

Acute Aortoiliac Occlusion
If a patient presents with new onset bilateral ALI, suspect possible occlusion of the aorta or aortoiliac segment. Etiologies include thrombosis or rupture of AAA, aortic dissection, or large saddle embolism

3. ankle pressure 50 mmHg, toe pressure <30 mmHg, and/or ABI <0.40
   - distal pulses are absent
   - signs of poor perfusion: hair loss, hypertrophic nails, shiny skin, atrophic muscle, ulcerations and infections, slow capillary refill, prolonged pallor with elevation and rubor on dependency, and venous troughing (Buerger's sign/Buerger's angle) (collapse of superficial veins of foot)
4. high-risk of 1 yr limb amputation (25%) and mortality (25%)
5. usually the result of multilevel occlusive arterial disease in the lower extremity

Investigations

- routine blood work, fasting metabolic profile
- ankle pressure and ABI: highest ankle pressure (dorsalis pedis or posterior tibial) for each side divided by highest brachial pressure (see Table 2 for cut-offs)
- toe pressure and TBI: highest pressure in the great toe for each side divided by highest brachial pressure; useful in patients with non-compressible vessels
- arterial DUS: combines b-mode and Doppler U/S to visualize blood vessels and characterize flow and plaques
- non-invasive: CTA and MRA excellent for large arteries (aorta, iliac, femoral, popliteal) but may have difficulty with tibial arteries (especially in the presence of significant wall calcification)
  - requires IV injection of iodinated contrast for CTA (contrast-induced nephropathy risk), gadolinium for MRA (avoid in patients with severe renal failure)
  - used primarily for planning interventions
- invasive: arteriography
  - superior resolution to CTA/MRA, better for tibial arteries, can be done intraoperatively as part of intervention
  - can be diagnostic and/or therapeutic

Table 2. Ankle-Brachial Index Cut-Offs

ABI Recording	Degree of PAD
>1.30	Non-compressible vessel (e.g. wall calcification, common in DM)
0.91-1.30	Normal
0.71-0.90	Mild
0.50-0.70	Moderate
<0.5	Severe

Treatment

- goals
  - preserve viability (save the leg)
  - preserve life (avoid complicated procedures in sick patients)
  - improve function and alleviate symptoms
  - prevent deterioration and recurrence
- conservative
  - risk factor modification (smoking cessation, glucose control, treatment of HTN and hyperlipidemia)
  - structured exercise program (30-45 min 3x/wk): improves collateral circulation and muscle oxygenation
  - foot care (especially in DM): trim toenails, check between toes for skin breaks, wear socks and shoes, clear shoes of any debris, keep wounds clean/dry, avoid trauma and pressure on wounds
- pharmacotherapy
  - for global cardiovascular protection since patients with PAD are at increased risk for CAD and CVD
  - antiplatelet agents (e.g. ASA, clopidogrel)
  - anticoagulants (e.g. low-dose rivaroxaban)
  - statin
  - ACEI/ARB
- surgical
  - indications: severe lifestyle impairment, vocational impairment, CLTI
  - revascularization
    - endovascular (angioplasty ± stenting)
    - endarterectomy: removal of plaque and repair with patch (usually distal aorta or common/deep femoral)
    - bypass graft sites:
      - anatomic: aortofemoral, femoropopliteal, popliteal-tibial bypass
      - extra-anatomic: axillofemoral, femorofemoral, femorotibial bypass
    - graft choices: saphenous vein graft (reversed or *in situ*), synthetic (polytetrafluoroethylene graft, e.g. Gore-Tex® or Dacron®), cryo-preserved homograft
- amputation: if not anatomically suitable for revascularization, persistent serious infections/gangrene, unremitting rest pain that is poorly controlled with analgesics, medically unfit for revascularization

Leriche Syndrome
Chronic aortoiliac occlusive disease presenting with a triad of:
1. Claudication (of buttocks and thighs)
2. Decreased femoral pulses
3. Erectile dysfunction/impotence

Subclavian Steal Syndrome
A chronic arterial disease of the upper limb where stenosis or occlusion of the proximal subclavian artery results in retrograde flow from the vertebral artery, compromising vertebrobasilar circulation. Patients can present with pre/syncope and neurological deficits especially upon exertion of the limb (rare), though most usually exhibit diminished BP with an associated finding of retrograde vertebral artery flow

Differential Diagnosis of Lower Extremity Pain

Vascular
- Atherosclerotic disease
- Fibromuscular dysplasia
- Popliteal entrapment syndrome
- Venous claudication/hypertension

Neurogenic
- Neurospinal disease (e.g. spinal stenosis)
- Complex regional pain syndrome
- Radiculopathies
- Diabetic neuropathy

MSK
- Osteoarthritis
- Rheumatoid arthritis/connective tissue disease
- Remote trauma
- Medial tibial stress syndrome
- •Sprain/strain

Treating PAD
Note that symptoms do not necessarily correlate with ABI measurement, e.g. a patient with ABI of 0.45 may be asymptomatic. Intervention is guided mainly by the patient's clinical presentation

The ABCDEs of PAD Treatment
- **A** **ANTI-PLATELET** (ASA, clopidogrel), anti-coagulant (if indicated), **ACEI/ARB**
- **B** BP control; target sBP <140 mmHg, β-blocker (if indicated)
- **C** Cholesterol management (**statin**); target LDL-C <2 mmol/L, smoking cessation
- **D** Diabetic control; target HbA1c <7%, diet/weight management
- **E** Exercise (3x/wk, 30-45 min per session)

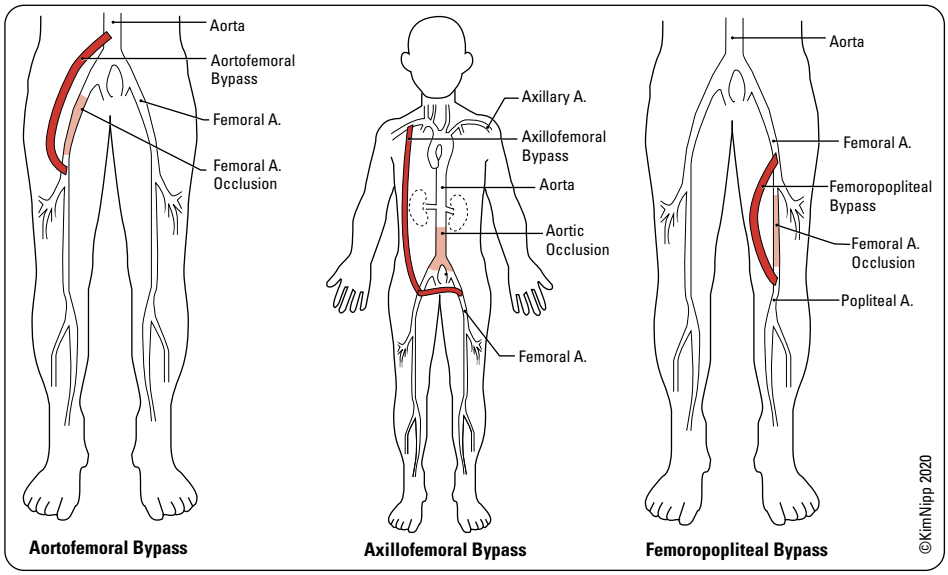

Figure 2. Aortofemoral bypass, axillofemoral bypass, and femoropopliteal bypass

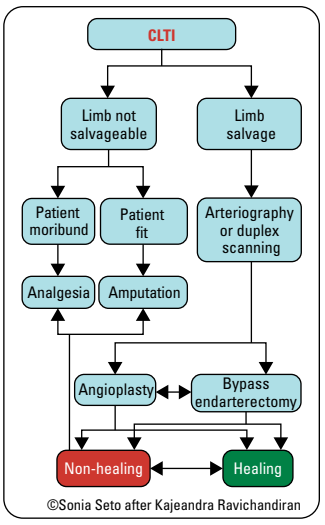

Figure 3. Treatment options for CLTI
Modified from Beard JD. Chronic lower limb ischemia.
BMJ 2000;320:854-857

Prognosis
- claudication: conservative therapy: 60-80% improve, 20-30% stay the same, 5-10% deteriorate, 5% will require intervention within 5 yr, <4% will require amputation
- for patients with CLTI, at 1 yr: 25% risk of mortality (secondary to CVA/MI), 25% risk of major amputation, 50% alive with two limbs, 33% 5 yr survival rate

Aortic Disease

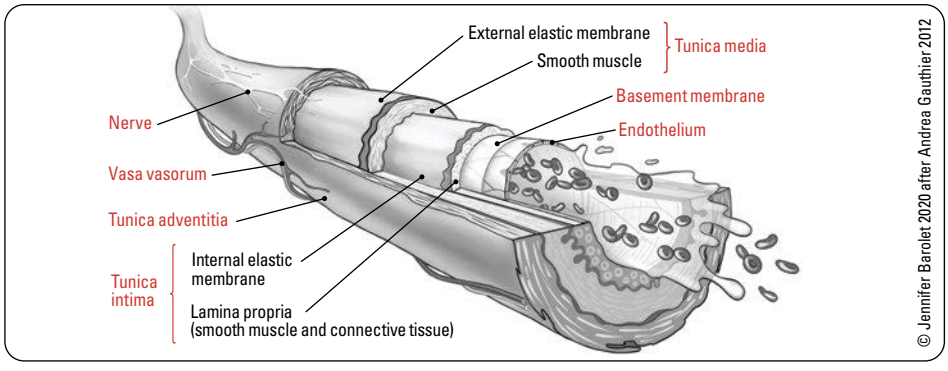

Figure 4. Arterial structure

Aortic Dissection

Definition
- tear in aortic intima allowing blood to dissect into the media
- Stanford classification: Type A (involve the ascending aorta) vs. Type B (distal to left subclavian artery)
- acute <2 wk (initial mortality 1% per h for Type A dissections)
- chronic >2 wk

Etiology
- most common: chronic and/or uncontrolled HTN
- other: connective tissue disease (e.g. Marfan syndrome, Ehlers-Danlos type IV syndrome), cystic medial necrosis, atherosclerosis, congenital conditions (e.g. coarctation of aorta, bicuspid aortic valves, patent ductus arteriosus), infection (e.g. syphilis), trauma, arteritis (e.g. Takayasu's)

Epidemiology
- M:F=3:1
- small increased incidence in African-Canadians (related to higher incidence of HTN); lowest incidence in Asians
- peak incidence: ages 50-65; ages 20-40 with connective tissue diseases

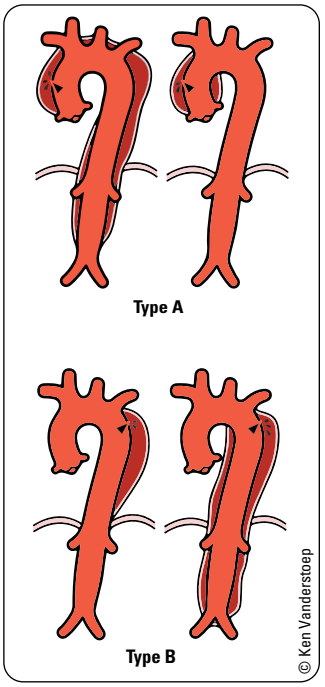

Figure 5. Stanford classification of aortic dissection

Clinical Features
- sudden onset tearing chest or back pain that radiates distally or between the scapulae with:
  - HTN
  - ischemic syndromes due to occlusion of aortic branches: coronary (MI), carotids (ischemic stroke, partial Horner's syndrome), splanchnic (mesenteric ischemia), renal (AKI), peripheral (ischemic leg), intercostal vessels (spinal cord ischemia)
  - "unseating" of aortic valve cusps (new diastolic murmur in 20-30%) in Type A dissection can lead to severe aortic insufficiency
  - rupture into pleura (dyspnea, hemoptysis), retroperitoneum (hypotension, shock), or pericardium (cardiac tamponade in Type A dissection)
  - syncope

Investigations
- CTA is the mainstay for both diagnosis and determining the type and extent of dissection; MRA may also be used if CTA is contraindicated
- ECG to rule out cardiac causes: LV hypertrophy ± ischemic changes, pericarditis, heart block, MI
- CXR: widened mediastinum, hemothorax if ruptured, apical pleural cap
- TEE: can visualize aortic valve and thoracic aorta but not abdominal aorta; rule out intra-cardiac thrombus
- consider: lactate (elevated in ischemic gut, shock), amylase (rule out pancreatitis), troponin (rule out MI), CBC, electrolytes, creatinine (renal failure), LFTs (shock, liver)

Treatment
- Type A dissection needs referral to cardiac surgeon for urgent repair
  - resection of segment with intimal tear; reconstitution of flow through true lumen; replacement of the affected aorta with prosthetic graft
  - postoperative complications: renal failure, intestinal ischemia, stroke, paraplegia, persistent leg ischemia, death
  - 2/3 of patients die of operative or postoperative complications
  - initial mortality rate without surgery is 1% per h for first 24 h, 30% 1 wk, 80% 2 wk
- Type B dissection is usually managed medically in the absence of spinal/mesenteric/limb malperfusion syndrome
  - <10-20% require urgent operation for complications
  - acute therapy is typically with intravenous antihypertensives titrated to sBP of 100-120 mmHg measured by arterial line and HR of 50-65 bpm in critical care setting
  - may transition to oral meds after initial control
  - α and β-blocker to lower BP and decrease cardiac contractility (e.g. labetalol); nondihydropyridine CCB (e.g. diltiazem) if clear contraindications to β-blockers, and as second-line therapy; IV nitroglycerin also used as second-line agent
  - ACEI and/or other vasodilators if insufficient BP or HR control
  - selective intervention (endovascular or surgical) for complications or refractory symptoms/progression despite medical therapy
  - may be a subset of patients who could be well treated with early aortic stent-grafting after initial medical stabilization
  - with treatment, 60% 5 yr survival, 40% 10 yr survival
  - long term complications include aneurysmal degeneration of the aorta
- Type B dissection with spinal/mesenteric/renal/limb malperfusion and/or aortic rupture may be treated with TEVAR or open surgical repair

Aortic Aneurysm

Definition
- localized dilatation of an artery >1.5x normal diameter (3 cm and larger for abdominal aorta)
- true aneurysm: involves all vessel wall layers (intima, media, adventitia)
- false aneurysm (pseudoaneurysm): does not involve all layers; breach in intima/media that allows blood to collect between media and adventitia
- aneurysms can rupture, thrombose, embolize, erode, and fistulize

Classification
- shape
  - fusiform: concentric; involves full circumference of vessel wall
  - saccular: eccentric; involves only a portion of vessel wall (theoretical higher risk of rupture due to unequal distribution of pressure)
- location
  - TAA: ascending, transverse arch, descending
  - thoracoabdominal
  - AAA: 90-98% are infrarenal
    - suprarenal: starts above the renal arteries but does not involve the thoracic aorta
    - pararenal: starts at the renal arteries but the superior mesenteric artery origin is not aneurysmal

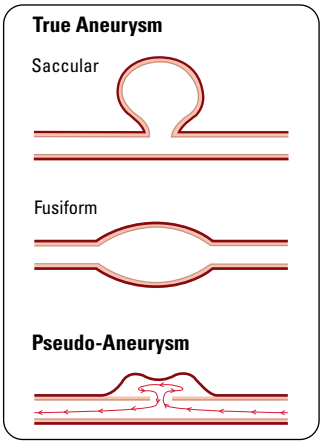

Figure 6. Classification of aneurysms

Ruptured AAA

Classic Triad
- Hypotension/collapse
- Back/abdominal pain
- Palpable, pulsatile abdominal mass (caution in patients with raised BMI)

Initial Management
- Intravenous access with two peripheral large bore IVs
- Permissive hypotension (sBP enough to maintain mental status)

- juxtarenal: starts immediately distal to renal arteries (there is no normal aorta immediately distal to the origin of the renal arteries); renal artery origin is not aneurysmal
- infrarenal: starts distal to the renal arteries (there is some normal aorta immediately distal to the origin of the renal arteries)

Etiology and Risk Factors

- risk factors: smoking (current or prior), advanced age, male sex, White race, FMHx, presence of other large vessel aneurysms, HTN
- degenerative
- traumatic
- mycotic (Salmonella, Staphylococcus, usually suprarenal aneurysms)
- connective tissue disorder (Marfan syndrome, Loeys-Dietz syndrome, Ehlers-Danlos type IV syndrome)
- vasculitis
- infectious (syphilis, fungal)
- ascending thoracic aneurysms are associated with bicuspid aortic valve
- aortic dissection
- congenital (i.e. Turner's syndrome)

Clinical Features

- 75% asymptomatic
- most commonly in the abdominal aorta
- common presentation: due to acute expansion or rupture
  - syncope
  - pain (chest, abdominal, flank, back)
  - hypotension
  - palpable pulsatile mass above the umbilicus
  - airway or esophageal obstruction, hoarseness (left recurrent laryngeal nerve paralysis), hemoptysis, or hematemesis (indicates thoracic or thoracoabdominal aortic aneurysm)
  - distal pulses may be intact

Canadian Society of Vascular Surgery 2018 AAA Screening Guidelines
Recommend:
- One time screening ultrasound for:
  - Men age 65-80
  - Women age 65-80 with smoking history or cardiovascular disease
  - First degree relatives after age 55
- Repeat ultrasound 10 yr after initial screening if aortic diameter >2.5 cm and <3 cm

Investigations

- blood work: CBC, electrolytes, urea, creatinine, PTT, INR, blood type, and crossmatch
- abdominal U/S (approaching 100% sensitivity, up to ± 0.6 cm accuracy in size determination) – useful for screening and surveillance
- CT with contrast (accurate anatomic visualization, size determination, EVAR planning)
- peripheral arterial DUS (rule out aneurysms elsewhere, e.g. popliteal)

Treatment

- conservative (for asymptomatic aneurysms that do not meet the size threshold for repair; see below)
  - cardiovascular risk factor reduction: smoking cessation; control of HTN, DM, hyperlipidemia, regular exercise, watchful waiting, U/S surveillance with frequency depending on size and location
- surgical
  - indications
    - ruptured
    - symptomatic (tenderness on palpation of the aneurysm)
    - AAA: size >5.5 cm (men) or >5.0 cm (women)
    - rapid growth greater than 0.5 cm/6 mo or 1 cm/yr
  - risk of rupture depends on: size, family history of rupture, rate of enlargement (>1 cm/yr in diameter), symptoms, and comorbidities (HTN, COPD, dissection), smoking
  - surgical options for AAA
    - open surgery (laparotomy or retroperitoneal)
      - complications
        - early: renal failure, spinal cord injury (paraparesis or paraplegia), impotence, arterial thrombosis, anastomotic rupture or bleeding, peripheral emboli, ischemia
        - late: graft infection/thrombosis, aortoenteric fistula, anastomotic (pseudo) aneurysm
        - death (2-5%)
    - EVAR
      - newer procedure
      - advantages: preferred to open surgery in higher risk patients with suitable anatomy; decreased perioperative morbidity and mortality, procedure time, need for transfusion, ICU admissions, length of hospitalization, and recovery time
      - disadvantages: endoleak rates as high as 20-50%, device failure increasing as longer follow-up periods are achieved, re-intervention rates 10-30%, cost-effectiveness is an issue, radiation exposure (especially in younger patients due to need for life-long follow-up)

- complications
  - early: immediate conversion to open repair (<1%), groin hematoma, arterial thrombosis, iliac artery rupture and thromboemboli, renal failure, impotence, ischemia
  - late: endoleak, graft kinking, stent fracture, device component separation and migration, thrombosis, rupture of aneurysm, complications of radiation exposure
  - death (1-2%, though may be up to 10% in elective advanced endovascular repair especially with proximal aortic and thoracoabdominal repairs)

Carotid Stenosis

Definition
- narrowing of the internal carotid artery lumen due to atherosclerotic plaque formation, usually near common carotid bifurcation into internal and external carotids (carotid bulb)

Risk Factors
- HTN, smoking, DM, CVD or CAD, dyslipidemia, older age

Clinical Features
- may be asymptomatic
- if symptomatic – TIA, ischemic stroke; may be hemispheric presentation (deficits contralateral to carotid lesion) or ocular presentation (deficits ipsilateral to carotid lesion – amaurosis fugax or retinal artery ischemia)
- physical exam
  - fundoscopy: cholesterol emboli in retinal vessels (Hollenhorst plaques)

Investigations
- CBC, PT/INR, PTT (hypercoagulable states)
- ECG, echo (rule out other causes of stroke)
- carotid duplex U/S or DUS: determines severity of disease (mild/moderate/severe stenosis or occlusion)
- angiography: CTA, MRA

Treatment
- generally the decision to treat with BMT alone vs. BMT + surgical management depends on whether stenosis is asymptomatic or symptomatic (see Table 3, VS10); size of infarct, patient functional recovery, life expectancy, and comorbidities are important in decision-making
- symptomatic carotid stenosis is defined as focal neurologic deficits referable to carotid artery distribution occurring within the past 6 mo with >50% stenosis; ideally surgical treatment should be done within the first 48 h to 2 wk of symptom onset
- lifestyle modifications: smoking cessation, weight loss, dietary changes, exercise

1. medical management
- anti-hyperglycemics: if concomitant DM
- anti-hypertensives: target BP <140/90 or <140/85 if concomitant DM
- statins: aggressive management to achieve LDL-C reduction; plaque stabilization effect
- anti-platelet agents (ASA ± clopidogrel): confer ~25% relative risk reduction

2. surgical management
- CEA or CAS for symptomatic carotid stenosis
- CEA: generally mainstay of treatment
- CAS: indicated if poor surgical access, radiation-induced stenosis, or comorbidities that increase risk of surgery/anesthesia
- aggregate risk of death, stroke, or MI in periprocedural period is not significantly different between CEA or CAS
  - higher risk of periprocedural stroke in CAS
  - higher risk of MI and temporary cranial nerve palsy in CEA

10 Yr Stroke Prevention after Successful Carotid Endarterectomy for Asymptomatic Stenosis (ACST-1): A Multicentre Randomised Trial
Lancet 2010;376:1074-1084
Study: Asymptomatic Carotid Surgery Trial (ACST), an RCT with follow-up at 10 yr.
Patients: 3120 asymptomatic patients with significant carotid artery stenosis (126 centres in 30 countries) were randomized equally between immediate CEA and indefinite deferral of CEA and were followed for up until death or to a median of 9 yr among survivors (IRQ 6-11).
Main Outcome: Perioperative mortality and morbidity (death or stroke within 30 d) and non-perioperative stroke.
Conclusions: In asymptomatic patients under age 75 with significant carotid artery stenosis, successful CEA reduces the 10 yr stroke risk. Net benefit depends on risks from unoperated carotid lesions, future surgical risks, and whether life expectancy exceeds 10 yr.

Table 3. Indications for Medical vs. Surgical Management of Carotid Stenosis

Stenosis	Asymptomatic	Symptomatic
<50%	BMT	BMT
50-60%	BMT	
60-70%	BMT + Surgical management if: • Progression of disease • Young and otherwise healthy • Ocular ischemic syndrome • Life expectancy >5 yr • Surgeon's perioperative morbidity/mortality risk <3% 60-99% stenosis: ARR=1-3%; NNT~33	BMT + Surgical management if: Surgeon's perioperative morbidity/mortality risk <3% 50-70% stenosis: ARR=4.6%, NNT=22
70-99%	BMT + Surgical management if: Surgeon's perioperative morbidity/mortality risk <3% ARR=1-3%; NNT~33	BMT + Surgical management if: Surgeon's perioperative morbidity/mortality risk <3% ARR=16%; NNT~6
100%	BMT No surgical intervention	BMT No surgical intervention

ARR = absolute risk reduction; NNT = number needed to treat

Venous Disease

Venous Thromboembolism

- see Hematology, H36

Chronic Venous Insufficiency

Definition

- wide spectrum of chronic venous disease with advancing symptoms of edema, skin changes, varicosities, or leg ulcers

Epidemiology

- primary venous insufficiency is the most common venous disorder of the lower extremities
- 65% of North American adult population develops some degree of venous insufficiency

Etiology

- spectrum of chronic venous disease involving deep and superficial lower extremity veins caused by calf muscle pump dysfunction, venous obstruction, and chronic valvular incompetence (reflux) due to phlebitis, varicosities, or DVT
- final common pathway is development of venous hypertension, leading to histologic and physiologic inflammatory changes
- primary (99% of cases) venous insufficiency: venous valve incompetence or obstruction
  - suspected risk factors: increasing age, systemic hormonal contraceptive use, prolonged standing, pregnancy, obesity
- secondary venous insufficiency: DVT, malignant pelvic tumours with venous compression, congenital anomalies, arteriovenous fistulae, trauma, pregnancy

Clinical Features and Complications

- pain (most common) described as fullness/tightness and aching; worst at end of the day
- telangiectasias or reticular veins: dilated intradermal and subdermal veins, respectively (<3 mm in diameter) (CEAP classification C1, Table 4)
- varicose veins: visible, long, dilated, and tortuous superficial veins (great or small saphenous veins and tributaries) resulting from incompetent valves in the deep, superficial, or perforator systems (>3 mm in diameter) (CEAP C2)
- ankle and calf edema; relieved by foot elevation (CEAP C3)
- burning, aching, fullness/tightness

May-Thurner Syndrome
In affected individuals, the right common iliac artery compresses the left common iliac vein, resulting in venous congestion and possible DVT of the left leg
Consider in patients presenting with left leg thrombosis and no clear underlying hypercoagulability

- skin changes:
  - eczema, stasis dermatitis, pruritus, brownish hyperpigmentation (hemosiderin deposits) (CEAP C4a)
  - subcutaneous fibrosis if chronic (lipodermatosclerosis or "inverted champagne bottle legs"), atrophie blanche (CEAP C4b)
- ulceration: shallow, above medial malleolus (gaiter area), weeping (wet), painless, irregular outline:
  - healed venous ulcer (CEAP C5)
  - active venous ulcer (CEAP C6)
- recurrent superficial thrombophlebitis and DVT
- bleeding or hematoma of varicosities secondary to trauma

Table 4. CEAP Classification of Venous Disease

	Clinical		Etiological		Anatomical		Pathophysiological
C0	No clinical signs of disease	Ec	Congenital	As	Superficial veins	Pr	Reflux
C1	Telangiectasia or reticular veins	Ep	Primary	Ap	Perforating veins	Po	Obstruction
C2	Varicose veins	Es	Secondary	Ad	Deep veins	Pr,o	Reflux + obstruction
C3	Edema	En	No etiology identified	An	No venous location identified	Pn	No pathophysiology identified
C4: C4a C4b	Skin changes: Eczema, pigmentation Lipodermatosclerosis or atrophie blanche						
C5	Healed venous ulcers						
C6	Active venous ulcers						
S	Symptomatic						
A	Asymptomatic						

Investigations
- ABI (pre-compression to ensure no arterial disease)
- venous Doppler U/S or DUS

Treatment
- conservative
  - elastic compression stockings, ambulation, periodic rest-elevation, avoid prolonged standing
  - ulcers: wound care using multilayer compression bandage ± antibiotics ± debridement PRN
  - medical treatments are variable, e.g. pentoxifylline for venous ulcer healing, flavonoids (e.g. diosmin) for pain, etc.
- surgical
  - surgical destruction of vein with partial or complete removal; techniques include vein ligation/stripping, phlebectomy, perforator ligation
- indications for surgery:
  - documented reflux at the saphenofemoral or saphenopopliteal junction by DUS or Doppler U/S
  - failed trial of conservative treatment for >3 mo
  - signs of CVI (eczema, pigmentation, lipodermatosclerosis, ulceration) or complications associated with varicosities (ulceration due to venous stasis, hemorrhage from superficial varicosity, recurrent superficial thrombophlebitis, stasis dermatitis, varicose eczema, lipodermatosclerosis, unremitting edema/pain affecting quality of life and requiring chronic analgesia)
- 10 yr postoperative recurrence of 20%
- endovenous: laser therapy, radiofrequency ablation, foam/liquid/glue sclerotherapy

Lymphedema

Definition
- impaired lymphatic drainage resulting in accumulation of interstitial fluid and fibroadipose tissue

Etiology
- primary
  - congenital lymphedema (e.g. Milroy disease): presents age <2
  - lymphedema praecox (75% of primary cases): presents in adolescence at onset of puberty
  - lymphedema tarda: presents age >35
- secondary
  - infection: filariasis (roundworm parasitic infection; leading cause worldwide), cellulitis, lymphadenitis, tuberculosis
  - inflammation: rheumatoid arthritis, dermatitis, psoriasis, sarcoidosis
  - malignant infiltration/obstruction: axillary, groin or intrapelvic, pressure from large tumours

- iatrogenic: radiation/surgery (axillary, groin lymphadenectomy) (leading cause in North America), vein surgery, lymph node dissection, scarring
- traumatic injury and burns
- venous disease: CVI

Clinical Features
- classically non-pitting edema and hyperkeratotic cutaneous/subcutaneous changes with progressive disease
- impaired limb mobility, discomfort/pain, psychological distress
- positive Stemmer sign (sensitive): examiner unable to lift skin of thickened skin fold at the base of second toe or finger
- lipodermatosclerosis
- ulcerations

Investigations
- lymphoscintigraphy: most definitive test
- secondary causes of lymphedema must be evaluated and treated appropriately if found

Treatment
- conservative measures: avoid limb injury, treat skin infections early, skin hygiene, limb elevation, avoid prolonged sitting/standing/crossing legs
- external support: intensive (compression bandages) vs. maintenance (compression garments)
- exercise: gentle daily exercise of affected limb, gradually increasing range of motion (must wear compression garment while exercising)
- massage: manual lymph drainage therapy
- surgical: physiological (early disease: increase lymphatic drainage) lymphovenous bypass vs. reductive (advanced disease: remove fibroadipose deposits)

Landmark Vascular Surgery Trials

Trial Name	Reference	Clinical Trial Details
ARTERIAL DISEASE		
BASIL	J Vasc Surg 2010;51(5 Suppl):5S-17S	**Title**: Bypass vs. Angioplasty in Severe Ischemia of the Leg (BASIL) Trial: An Intention-to-Treat Analysis of Amputation-Free and Overall Survival in Patients Randomized to a Bypass Surgery (BSX)-First or a Balloon Angioplasty (BAP)-First Revascularization Strategy **Purpose**: Determine the optimal first line revascularization surgery between bypass surgery and balloon angioplasty in severe leg ischemia. **Methods**: 452 enrolled patients in 27 United Kingdom hospitals, half were randomised to BSX-first and half to BAP-first. All patients were monitored for 3 yr and more than half were monitored for >5 yr. **Results**: AFS (Amputation Free Survival) and OS (Overall Survival) did not differ between treatments during follow-up. BSX-first patients who survived 2 yr post randomization had a reduced hazard ratio for subsequent AFS of 0.85% (CI, 0.5 to 1.07; P=0.108) and for subsequent OS of 0.61% (95% CI, 0.50 to 0.75; P=0.009) in an adjusted time-dependent Cox proportional hazards model. **Conclusions**: No significant difference in amputation-free survival and overall survival between severe limb ischemia patients treated with bypass surgery and those treated with balloon angioplasty.
VOYAGER	NEJM 2020;382:1994-2004	**Title**: Rivaroxaban in Peripheral Artery Disease after Revascularization **Purpose**: To investigate the efficacy and safety of rivaroxaban for patients with PAD who have undergone lower extremity revascularization. **Methods**: Patients with PAD who had undergone revascularization were randomized to receive rivaroxaban plus Aspirin® or placebo plus Aspirin®. The primary efficacy outcome was a combination of acute limb ischemia, major amputation, myocardial infarction, ischemic stroke, or death. The primary safety outcome was major bleeding. **Results**: The 3-yr incidence of the primary efficacy outcome was 17.3% and 19.9% (hazard ratio, 0.85, 95% CI, 0.76 to 0.96; P=0.009) in the rivaroxaban and the placebo group, respectively. The primary safety outcome occurred in 2.65% and 1.87% (hazard ratio, 1.43; 95% CI, 0.97 to 2.10; P=0.07) of the rivaroxaban and the placebo group, respectively. **Conclusions**: In patients with PAD, there was significantly lower mortality and morbidity in patients treated with ASA and rivaroxaban than those treated with ASA alone.
AORTIC DISEASE		
EVAR1	NEJM 2010;362:1863-1871	**Title**: Endovascular vs. Open Repair of Abdominal Aortic Aneurysm **Purpose**: To evaluate the long-term outcome of EVAR compared with open repair of large aneurysms. **Methods**: Between 1999 to 2004, 1252 patients with large AAA (≥5.5 cm in diameter) were randomized to undergo either EVAR or open repair. Patients were followed for rates of death, graft-related complications, reinterventions, and resource use until end of 2009. **Results**: The 30-day operative mortality was 1.8% in the EVAR group and 4.3% in the open-repair group (odds ratio, 0.39; 95% CI, 0.18 to 0.87; P=0.02), but by the end of the study there was no significant difference in the rate of death from any cause (hazard ratio, 1.03; 95% CI, 0.86 to 1.23; P=0.72). The rates of graft-related complications and reinterventions were 3-4 times higher in the EVAR group. **Conclusions**: In patients with large AAAs, there was no significant difference in mortality in patients treated with open surgical repair and those treated with EVAR. Patients treated with EVAR had lower operative mortality but a higher incidence of graft-related complications, graft-related reinterventions, and healthcare costs.
IMPROVE	BMJ 2017;359:j4859	**Title**: Comparative Clinical Effectiveness and Cost Effectiveness of Endovascular Strategy vs. Open Repair for Ruptured Abdominal Aortic Aneurysm: 3-yr Results of the IMPROVE Randomised Trial **Purpose**: To compare the clinical outcomes and cost effectiveness of endovascular repair vs. open repair for patients with suspected ruptured AAA. **Methods**: 502 patients who underwent emergency repair for rupture were randomized to endovascular strategy or open repair. **Results**: Similar mortality between strategies by 90 days. There was lower mortality (48% vs. 56%), improved QALYs of 0.17 (95% confidence interval 0.00 to 0.33), and lower average costs of £2605 (95% confidence interval −£5966 to £702) in the endovascular strategy than the open repair group at 3 yr. **Conclusions**: At 3 yr, endovascular strategy for suspected AAA was associated with better outcomes and was more cost-effective than open repair.

CAROTID DISEASE		
MATCH	Lancet 2004;364:331-337	**Title**: Aspirin® and Clopidogrel Compared with Clopidogrel Alone after Recent Ischaemic Stroke or Transient Ischaemic Attack in High-Risk Patients (MATCH): Randomised, Double-Blind, Placebo-Controlled Trial **Purpose**: To compare the benefits of adding ASA to clopidogrel vs. clopidogrel alone in prevention of vascular events with higher bleeding risk. **Methods**: 7599 patients with recent ischaemic stroke or TIA with vascular risk factor(s) that were already receiving clopidogrel were randomized to either ASA or placebo. The primary endpoint was the first occurrence of an event in the amalgamation of ischaemic stroke and related vascular complications. **Results**: 15.7% of patients in the ASA and clopidogrel group acquired primary endpoint, compared with 16.7% in the clopidogrel alone group (relative risk reduction 6.4%, (95% CI -4.6 to 16.3); absolute risk reduction 1% (-0.6 to 2.7)). Major and life-threatening bleedings were higher in the ASA and clopidogrel group compared to clopidogrel alone group but there was no difference in mortality. **Conclusions**: The addition of ASA to clopidogrel monotherapy in patients with prior ischemic stroke or TIA did not prevent recurrence of ischemic stroke, TIA, or related complications. Dual therapy was associated with a greater risk of major hemorrhage.
CREST	NEJM 2010;363:11-23	**Title**: Stenting vs. Endarterectomy for Treatment of Carotid-Artery Stenosis **Purpose**: To compare outcomes of CAS vs. CEA for patients with symptomatic or asymptomatic extracranial carotid artery stenosis. **Methods**: Patients with symptomatic or asymptomatic carotid stenosis were randomly assigned to CAS or CEA. The primary endpoint was a composite of stroke, myocardial infarction, or death from any cause during the perioperative period or any ipsilateral stroke in the following 4 yr. **Results**: The estimated 4-yr rates of the primary endpoint between the stenting group and the endarterectomy group were 7.2% and 6.8%, respectively (hazard ratio with stenting, 1.11; 95% confidence interval, 0.81 to 1.51; P=0.51), with no differential treatment effect based on symptomatic status (P=0.84). **Conclusions**: In patients with asymptomatic or symptomatic carotid artery stenosis, there were no significant differences in the combined risk of stroke, MI, or death between those who underwent CEA compared to those who underwent CAS. CEA was associated with a greater risk of MI, while CAS was associated with a greater risk of stroke in the postprocedural period.
VENOUS DISEASE		
ESCHAR1	Br J Surg 2005;92:291-297	**Title**: Randomized Clinical Trial of Compression Plus Surgery vs. Compression Alone in Chronic Venous Ulceration (ESCHAR Study)--Haemodynamic and Anatomical Changes **Purpose**: To evaluate the effects of superficial venous surgery and compression on legs with chronic venous ulceration. **Methods**: Patients with open or recently healed leg venous ulceration and saphenous reflux were randomized to either compression bandaging or superficial venous surgery plus compression. Venous refill times (VRTs) were calculated via photoplethysmography before treatment and at 1 yr later. **Results**: Out of 214 legs, 112 underwent compression bandaging and 102 underwent compression plus surgery. Saphenous surgery eliminated deep reflux in 10/ 22 legs with segmental deep reflux and 3/17 with total deep reflux. Median VRT increased from 10 to 15 seconds 1 yr later (P<0.001). **Conclusions**: Superficial venous surgery was effective in improving venous hemodynamics in patients with active or healed venous ulceration.
ESCHAR2	BMJ 2007;335:83	**Title**: Long Term Results of Compression Therapy Alone vs. Compression Plus Surgery in Chronic Venous Ulceration (ESCHAR): Randomised Controlled Trial **Purpose**: To evaluate whether superficial venous surgery in addition to compression bandaging prevents recurrent leg ulcers. **Methods**: Patients with open or recently healed leg ulcers and superficial venous reflux underwent either compression plus saphenous surgery or compression alone. Primary outcomes were ulcer healing and ulcer recurrence. **Results**: At three yr, ulcer healing rates were 93% for the compression plus surgery group and 89% for the compression alone group (P=0.73). At four yr, the rates of ulcer recurrence were 31% for the compression plus surgery group and 56% for the compression alone group (P<0.01). **Conclusions**: Superficial venous surgery and compression bandaging was effective in reducing the recurrence of venous ulcers compared to compression bandaging alone. Superficial venous surgery and compression bandaging did not reduce the healing time of venous ulcers compared to compression bandaging alone.
